PRINCIPAL CONTENTS.

ENCYCLOPÆDIA BRITANNICA.

MOTANABBI, or MOTENEBBI. Abú 'l-Ṭayyib Aḥmed ibn al-Ḥosain of Cufa, called Al-Motanabbi (915/6-965), is the most famous representative of the last period of Arabic poetry, though some Eastern critics place him below Abú Tammám. He was the son of a water-carrier, and is said to have picked up much of the literary knowledge for which he was afterwards famous by haunting the book-stalls of his native city. He spent, too, some years of his youth among the nomads of the Syro-Arabian desert, learning their purer dialect and becoming imbued with their self-reliant spirit. Thus he grew up a brave proud man, a gallant warrior as well as a poet, full of ambition, not easily satisfied either with wealth or honours, indifferent to the Koran and to the fasts and prayers of Islam, but untainted by the looseness of morals common to the poets of those days. Such a character was not well fitted for the part of a courtier, the only career that then lay open to a poet; for, though no Arab poet deems himself humiliated by the most extravagant praises of a generous patron, and none has written in this vein more extravagantly than Abú 'l-Ṭayyib, he was as exacting of due acknowledgment as prodigal of adulation, and was too proud to endure a slight, even where it was dangerous to show resentment. At first he essayed a greater and more perilous road to distinction, appearing in the character of a prophet in the desert between the Euphrates and Syria, where he formed a considerable party, but was arrested by the governor of Emesa. A prison and the pillory cooled his enthusiasm; his prophetic pretensions indeed are hardly a proof of genuine religious fervour, for in the lands of Islam a revolutionary popular leader almost necessarily seeks a supernatural sanction for his attempt. The name of Al-Motanabbi (he who plays the prophet) clung to him, however, and is that by which he is still commonly known. Regaining his liberty, he had to struggle for a time with poverty and neglect. But his poetical talents at length found him patrons, and in 337 A.H. (948/9 A.D.) he became attached to the court of that famous warrior and patron of letters, Saif al-Dawla, prince of Aleppo, to whom many of the best fruits of his muse were dedicated, and by whose side he approved his valour in the field. But he had rivals who knew how to inspire jealousy between him and the prince, and an angry scene with the grammarian Khálawaih, in which the latter closed a philological dispute by striking Motanabbi on the face with a key which he had in his sleeve, in the very presence of the prince and without rebuke from him, led the poet to leave the court and seek a new career in the realm of the Ikhshídites. He now took as his patron and the object of his eulogies Káfúr, the regent of Egypt—a hideous black eunuch whom it was indeed a humiliation to praise, but who knew how to open the poet's lips by great gifts and honours. Motanabbi, however, sought a higher reward, the government of Sidon, and at length broke with Káfúr, wrote satires against him, and had to fly for his life to Cufa. A curious anecdote relating to this part of his career will be found in Lane's *Arabian Nights*, chap. viii. note 18. His next great patron was 'Adud al-Dawla of Shiráz, and on a journey from Shiráz to Cufa he was waylaid and slain, fighting bravely, by a chieftain of the Asad named Fátik, whose kinsfolk he had satirized (Sept. 965).

The poetry of Motanabbi is to European taste much less attractive than the verses of the ancient Arab poets, being essentially artificial and generally unreal, though it has great technical merits and displays lively fancy and considerable inventive power. It is mainly court poetry, but the poet has the credit of never losing his self-respect in the presence of his patrons. Oriental taste, on the other hand, places him on a very high pedestal, as may be judged from the fact that more than four hundred commentaries were written on his *Díwán* (H. Khal., iii 306). Dieterici's edition of the poet, Berlin, 1858-61, gives the commentary of Wáḥidí; the Egyptian edition of 1870 has the commentary of 'Okbarí.

See Abulfeda, *Ann. Mosl.*, ii 482 *sq.*; Ibn Khallikan, ed. De Slane, p. 51 *sq.*, and the notes to De Slane's translation; De Sacy, *Chrest. Ar.*, vol. iii.; Bohlen, *Commentatio de Motenebbio*, Bonn, 1824; Dieterici, *Mutanebbi und Seifuddaula*, Leipsic, 1847.

MOTHER-OF-PEARL. The shells of many molluscous animals display a brilliant pearly and iridescent lustre, resulting from the peculiar manner in which the layers of calcareous matter of which they are composed have been successively formed. Such shells, even when small in size, form bright and, specially to the untutored eye, attractive ornaments, and as such are used for necklaces and similar purposes. When the shells are of sufficient size to cut and shape for purposes of utility, they become an article of some commercial importance under the name of Mother-of-Pearl. This term, though applicable to all pearly shells, is in commerce principally applied to the shells of the bivalve pearl-mussel *Meleagrina margaritifera*, which is

the principal source of the commercial product. The *Meleagrina margaritifera* is a native of tropical seas, and is found around the coasts of all the lands within the tropics. The shells vary in size, the largest reaching to about the dimensions of a dessert plate, with a weight of from 1 to $1\frac{1}{4}$ lb. They also vary in colour to a considerable extent, some being dark and smoky round the outer edge with little iridescence, others dark but possessing a rich play of colours, and the greater part pearly white with varying iridescence. The principal sources of supply are the islands of the East Indian archipelago, the Pacific islands, the north-west Australian coast, the Persian and Red Seas, and the Gulf of Panama. The largest and steadiest consumption of mother-of-pearl is in the button trade, and much is also consumed by cutlers for handles of fruit and dessert knives and forks, pocket-knives, &c. It is also used in the inlaying of Japanese and Chinese lacquers, European lacquered papier-mâché work, trays, &c., and as an ornamental inlay generally. In an innumerable variety of small and fancy articles mother-of-pearl is also employed, its use being limited only by the moderate dimensions and thickness of material obtainable, and its rather brittle nature. The carving of pilgrim shells and the elaboration of crucifixes and ornamental work in mother-of-pearl is a distinctive industry of the monks and other inhabitants of Bethlehem. Among the South Sea Islands the shell is largely fashioned into fishing-hooks, a purpose for which its brilliant conspicuous appearance appears to render it suitable without the addition of any bait or other lure. Among shells other than those of *Meleagrina margaritifera* used as mother-of-pearl may be mentioned the Green Ear or Ormer shell (*Haliotis tuberculata*) and several other species of Haliotis, besides various species of Turbo.

The pearl-shell fishery is an important industry on the north and north-west coasts of Australia, producing about 800 tons yearly, valued at over £100,000, the Papuan islanders of Torres Straits being employed as divers under European supervision, with skilled appliances. The shell of the golden-tipped variety of Avicula found here is much more valuable than the dark-edged one of the South Seas. The value of the fisheries depends much more on the shell than on the occasional pearls found, which indeed are sometimes, along with the "fish," a perquisite of the diver; but on the west coast, about Shark's Bay, a smaller variety of the same mollusc produces valuable pearls, their exciting cause being possibly present there in greater abundance. That the pearl itself is not due to disease, or to the presence of any irritating cause, seems clear from the fact that the mollusc can reject it at will, and often does so when taken (for which reason the diver, in seizing him, at once places his hand over the opening so as to close the shell); but it is believed now that the pearl is secreted and held ready to be dissolved by the powerful acid of the sac, and spread in nacreous layers over the spot irritated by the borer (*Pholas* sp.). Accordingly pearls are seldom found in the young "fish," whose shells are much harder outside, and not susceptible to such attacks. A mass of nacreous layers formed round a point of irritation or "blister" can sometimes be cut out of the shell, and might easily be mistaken for (and sold as) a pearl, but it is never quite perfect all round and is always hollow. Sometimes, after having secured the loose pearls, the fishermen deposit the mollusc again, unharmed, in a secure and accessible locality, and repeat the process for three and four years successively.

MOTHERWELL, a police burgh of Lanarkshire, Scotland, is situated on the Caledonian Railway a short distance from the right bank of the Clyde, 2 miles north-east of Hamilton and 11 east-south-east of Glasgow. The village, which takes its name from an old well dedicated to the Virgin, contained only 900 inhabitants in 1851, and owes its rapid increase to the coal and iron mines in the neighbourhood. It possesses one of the largest ironworks in Scotland, and also extensive engineering works. Motherwell was erected into a police burgh in 1865. The population in 1871 was 5746, and in 1881 it was 12,904.

MOTHERWELL, WILLIAM (1797-1835), poet, antiquary, and journalist, born in 1797, rendered service in the collection of fugitive border poetry and wrote one or two very touching songs in the Scotch dialect, dying before he had fulfilled the promise of his earlier work. His short life was diversified by few incidents. The son of an ironmonger in Glasgow, he was educated partly in Edinburgh and partly in Paisley. At the age of fifteen he was apprenticed in the office of the sheriff-clerk at Paisley, and appointed sheriff-clerk depute there in 1819. The impulse given by Scott to the pursuit of local ballads was still strongly in force, and the young law apprentice spent his leisure in collecting materials for a volume which he published in 1819 under the title of *The Harp of Renfrewshire*. In the course of the next eight years he extended his studies in the same field and published the results in 1827 in *Minstrelsy Ancient and Modern*, prefaced by a very thorough historical introduction. Meantime he made a reputation by casual poems in newspapers and magazines, of which *Jeanie Morrison*, *My Heid is like to break*, and *Wearie's Cauld Well* have taken a fixed place in Scotch literature. These poems are his best work, but he gave most of the energy of his vigorous intellect to writing ballads and songs in English; and he interpreted the martial spirit of the Norse sea-rovers with an enthusiasm and force which one would not expect from the plaintive character of his Scotch poems. His critical power and his learning were probably too great for his executive faculty; but, whatever may be thought of his promise as a poet, it was undoubtedly quenched by his entrance into journalism and the fatiguing work of newspaper editing. He became editor of the *Paisley Advertiser* in 1828, of the *Glasgow Courier* in 1830, and died suddenly of apoplexy in 1835. A trying examination before a Parliamentary Committee was thought to have hastened his end; but Conservative journalism at the time of the Reform Bill was exciting and uphill work, and it is a fair inference from the sad tone of some of his later poems that a baffled longing to achieve enduring fame added to the poet's worries and increased the strain on his constitution. A small volume of his poems was published in 1832, and a larger volume with a memoir in 1849.

MOTHS. See BUTTERFLIES.

MOTLEY, JOHN LOTHROP (1814-1877), the well-known historian of the Dutch Republic, was born on 15th April 1814 at Dorchester, now a part of Boston, Massachusetts, and from 1827 was educated at Harvard, where he graduated in 1831. He then studied for two years at Göttingen and Berlin, and after a period of European travel, chiefly in Italy, returned to America in 1834, where he became a student of law, and ultimately was called to the bar. In 1837 he married, and two years afterwards he published anonymously his earliest literary work, a two-volume novel, entitled *Morton's Hope, or the Memoirs of a Young Provincial*, which attained, and indeed deserved, only a moderate success. In 1841 he received his first diplomatic appointment, being made secretary of legation to the Russian mission, but, finding the atmosphere of St Petersburg uncongenial, he resigned his post within a few months and definitely resolved on a literary career. Besides contributing various historical and critical essays to the *North American Review*, he published in 1849, again anonymously, a second novel entitled *Merry Mount, a Romance of the Massachusetts Colony*. About the year 1846 the project of writing a history of Holland had begun to take shape in his mind, and he had already prepared a considerable quantity of MS., when, finding the materials at his disposal in the United States quite inadequate for the completion of his work, he resolved to migrate to Europe along with his family in 1851. The next five years were spent at Berlin, Dresden, Brussels, and the Hague in laborious investigation of the archives preserved in those capitals, and resulted in 1856 in the publication of *The Rise of*

the Dutch Republic, a History (London and New York, 3 vols. 8vo). This work, which, after a large historical introduction, minutely follows the history of the Low Countries from the abdication of Charles in 1555 down to the assassination of William the Silent in 1584, immediately became highly popular by its graphic manner and the warm and sympathetic spirit in which it was written, while at the same time it was frankly recognized by scholars as a painstaking and conscientious piece of original work. It speedily passed through many English editions, was translated into French (with an introduction by Guizot) in 1859, and also into Dutch (with introduction and notes by Bakhuizen van den Brink, himself a distinguished historian), as well as into German and Russian. Pursuing his researches in England, France, Belgium, and Holland, Motley was able to publish in 1860 the first two volumes of the *History of the United Netherlands*, covering the period from the death of William the Silent in 1584 to shortly after the destruction of the Armada, by which the Spanish project for subjugating England and reconquering the Netherlands was finally defeated. This work, which was on a somewhat larger scale than the preceding, embodied the results of a still greater amount of original research, not only in the Dutch archives, in the copies of the Simancas archives, and in the portions of those archives still retained in Paris, but also in the London State Paper Office, and in the MS. department of the British Museum. By two new volumes published in 1868 the work was brought down to the twelve years' truce in 1609, and it was announced that the author was engaged in writing a continuation which should embrace the history of the Thirty Years' War. Meanwhile Motley from the close of 1861 to 1867 had held the post of United States minister at Vienna; in 1869 he was appointed to a similar position at the court of St James's, but was recalled in 1870. After a short visit to Holland he again took up his residence in England, where *The Life and Death of John Barneveld, Advocate of Holland, with a view of the primary Causes of the Thirty Years' War* (2 vols.) appeared in 1874. Ill health now began to interfere with sustained literary work, and, after a protracted period of failing vigour, he died at Kingston Russell House, near Dorchester, Dorsetshire, on 29th May 1877.

Motley was member of a number of learned societies in Europe and America, and held a variety of honorary degrees. Among minor works not noticed above may be mentioned a pamphlet on the *Causes of the Civil War in America* (1861), which originally appeared in the correspondence columns of the *Times* newspaper, and *Democracy, a Historical Essay* (1869), originally delivered as an address to the New York Historical Society. The merits of Motley as an historian are undeniably great; he has told the story of a stirring period in the history of the world with full attention to the character of the actors and strict fidelity to the numerous vivid details of the action. But it may safely be said that his tale is best where most unvarnished, and probably no writer of the same rank has owed less to the mere sparkle of highly polished literary style.

See *John Lothrop Motley, a Memoir*, by Oliver Wendell Holmes (1878).

MOTMOT, according to Hernandez in his *Historia Avium Novæ Hispaniæ* (p. 52), published at Rome in 1651, was the Mexican name of a bird which he described well enough to leave no doubt as to what he meant; but the word being soon after printed *Momot* by Nieremberg and others gave rise to the Latinized *Momotus*, invented by Brisson as a generic term, which has since been generally adopted by ornithologists,[1] though Motmot has been retained as the English form. Linnæus knew of only one species of Motmot, and referred it to his genus *Ramphastos* (properly *Rhamphastus*) under the name of *R. momota*. This is the *Momotus brasiliensis* of modern ornithologists, and from its geographical range cannot be the original *Motmot* of Hernandez, but is most likely the "*Guira guainumbi*" of Marcgrave.

The Motmots have been for many years recognized as forming a distinct family, *Momotidæ* or *Prionitidæ*, of the heterogeneous assemblage known as *Picariæ* or *Coccygomorphæ*; and the only question among systematists has been as to their position in that group. This has been discussed and illustrated with his usual assiduity by Dr Murie (*Ibis*, 1872, pp. 383-412, pls. xiii.-xv.), who conclusively showed that the TODY (*q.v.*) was the Motmot's nearest existing relative, while he believed that both *Momotidæ* and *Todidæ* might be placed in one section (*Serratirostres*) with the *Coraciidæ* (ROLLER, *q.v.*), *Meropidæ*, and *Alcedinidæ* (*cf.* KINGFISHER, vol. xiv. p. 81). To the latter allocation Garrod (*Proc. Zool. Society*, 1878, pp. 100-102) has since partly demurred, though admitting the Kingfisher affinity, while upholding the former, and even declaring that Motmots and Todies form but a single family. As the conclusions of both these investigators are based on the sure ground of anatomical structure, they are of incomparably greater value than most of those arrived at by prior systematists who judged from external characters alone.

In outward appearance the Motmots have an undoubted resemblance to Bee-eaters, but, though beautiful birds, various shades of blue and green predominating in their plumage, they do not exhibit such decided and brilliant colours; and, while the Bee-eaters are only found in the Old World, the Motmots are a purely Neotropical form, extending from southern Mexico to Paraguay, and the majority of species inhabit Central America. They are said to be solitary birds, or at most living in pairs, among the gloomy forests, where they sit on the underwood nearly motionless, or only jerking their long tail as the cry "houtou" (or something like it) is uttered. Their ordinary food is small reptiles, insects, and fruits. The nest of one species, as observed by Mr Robert Owen, is at the end of a hole bored in the bank of a watercourse, and the eggs are pure white and glossy (*Ibis*, 1861, p. 65). Little else has been recorded of their ways.

The *Momotidæ* form but a small group, containing, according to the latest enumeration of them in 1873 by Messrs Sclater and Salvin (*Nomenclator*, pp. 102, 103), but seventeen species,[2] distributed into six genera, of which last, however, Dr Murie (*l.c.*) would only recognize four—*Momotus*, *Baryphthengus*, *Hylomanes*, and *Eumomota*—the second including *Urospatha*, and the last *Prionorhynchus*. The distinctions between these groups would require more space to indicate than can here be allowed; but it may be stated that, while all have a general resemblance in the serrated edges of the bill and many other characters, *Momotus* has the normal number of twelve rectrices, while the rest have only ten, which in *Hylomanes* have the ordinary configuration, but in adult examples of all the others the shaft of the median pair is devoid of barbs for the space of about an inch a little above the extremity, so as to produce a spatulate appearance, such as is afforded by certain humming-birds known as "Racquet-tails" (HUMMING-BIRD, vol. xii. p. 357), Kingfishers of the genus *Tangsiptera* (KINGFISHER, vol. xiv. p. 82), and Parrots of the group *Prioniturus*. Waterton (*Wanderings*, Journey 2, chap. iii.), mentioning the species *M. brasiliensis* by its native name "Houtou," long ago asserted that this peculiarity was produced by the Motmot itself nibbling off the barbs, and this extraordinary statement, though for

[1] Its barbarous origin induced Illiger to substitute for it the word *Prionites*, and his example has been followed by some nomenclatural purists.

[2] The same number was recognized by the first-named of these gentlemen in his review of the Family (*Proc. Zool. Society*, 1857, pp. 248-260), where they are all diagnosed, a species, subsequently described by Dr Cabanis (*Mus Heineanum*, ii p. 115), not being admitted.

a while doubted, has since been shown by Mr Salvin (*Proc. Zool. Society*, 1873, pp. 429-433), on Mr Bartlett's authority, to be perfectly true. The object with which the operation is performed is wholly unknown. It is sometimes incompletely executed, and the tail has then an asymmetrical form. This must have been the case with the example that Hernandez described (*l.c.*), and brought on himself the criticism of Willughby (*Ornithologia*, p. 298) for so doing. Much of the bibliography of the family is given in Dr Murie's paper already quoted; and it may be remarked that in 1734 Seba, probably misled by wrong information, figured (*Rerum Nat. Thesaur.*, tab. 67, fig. 2) under the name of "Motmot" a bird which has been identified with a species of GUAN (vol. xi. p. 232), and is the *Ortalis motmot* of modern ornithology. (A. N.)

MOTRIL, a town of Spain in the province of Granada, is charmingly situated at the foot of an offshoot of the Sierra Nevada, on the edge of a rich alluvial plain about a mile from the Mediterranean and 40 miles south-south-east from Granada, with which it is connected by a good carriage road. The town has no buildings of special architectural or historical interest. The climate is semi-tropical, and the "vega" or plain of Motril has been found peculiarly adapted for the culture of the sugar-cane, of which the annual average yield has recently been estimated at 113,636 tons. In the district there are five sugar-factories, —two in the immediate vicinity of the town, and three at Salobreña, a village about 3 miles to the westward at the mouth of the Rio Grande (Guadalfeo). Some cotton is also grown and manufactured. This neighbourhood is rich in lead, chiefly wrought by companies having very limited capital; the ore is for the most part smelted on the spot and afterwards sent to Malaga, or direct to England. Zinc and copper are also found, but in smaller quantities. Esparto grass is exported. The population of Motril in 1878 was 16,665. The harbour (El Puerto de Motril) lies about 6½ miles to the south-eastward at the village of Calahonda.

MOTT, VALENTINE (1785-1865), an eminent American surgeon, was born at Long Island, New York, on the 20th August 1785. He graduated at Columbia College, studied under Sir Astley Cooper in London, and also spent a winter in Edinburgh. After acting as demonstrator of anatomy he was appointed professor of surgery in Columbia College in 1809. From 1811 to 1834 he was in very extensive practice as a surgeon, and most successful as a teacher and operator. He tied the innominate artery in 1818; the patient lived twenty-six days. He performed a similar operation on the carotid forty-six times with good results; and in 1827 he was also successful in the case of the common iliac. He is said to have performed one thousand amputations and one hundred and sixty-five lithotomies. After spending seven years in Europe (1834-1841) Mott returned to New York and founded the university medical college of that city. He translated Velpeau's *Operative Surgery*, and was foreign associate of the Imperial Academy of Medicine of Paris. His death occurred on the 26th of April 1865.

MOTTEVILLE, FRANÇOISE BERTAUT, MADAME DE (1621-1689), was born in 1621. She was of fair family (the poet-bishop Jean Bertaut being her kinsman), and by her mother of Spanish blood. This circumstance attracted Anne of Austria to Madame Bertaut, and the child Françoise was made a member of the queen's household and pensioned at seven years old. The influence of Richelieu, however, who constantly endeavoured to deprive the queen of confidantes, exiled mother and daughter to Normandy. There, at the age of eighteen, Françoise married Nicholas Langlois, Seigneur de Motteville, first president of the Chambre des Comptes. She was very soon a widow, but she had before that date (1641) visited the court, renewed her relations with the queen, and been rewarded by a pension increased from 600 to 2000 livres. No sooner did Anne of Austria become her own mistress by the deaths of Richelieu and of her husband than she summoned Madame de Motteville to court and made her her most intimate friend. Through all the intrigues and troubles of the Fronde, Madame de Motteville preserved the honourable reputation of being devoted to her mistress without any party ties or interests. She was also on very intimate terms with Henrietta Maria of England during her residence in France. After Anne of Austria's death Madame de Motteville lived in retirement, but not in absolute seclusion, seeing especially Madame de Sévigné and Madame de la Fayette. She died on 29th December 1689. Some letters of hers are preserved, especially a curious correspondence with "La Grande Mademoiselle" on marriage, but her chief work is her *Mémoires*, which are in effect a history of Anne of Austria, written briefly till the date of Madame de Motteville's return to court, and then with fulness. The author is something of a partisan, but not an intentionally unfair one, and her judgment and power of observation are very considerable. The style of her book is not of the most peculiar or striking, but it is simple, easy, and good. The *Mémoires* may be most conveniently read in Michaud and Poujoulat's *Collection*, vol. xxviii.

MOUKDEN. See MANCHURIA, vol. xv. p. 466.

MOULINS, chief town of the French department of Allier, is situated 195 miles by rail south-south-east from Paris on the right bank of the Allier, which is here crossed by a remarkable bridge about 1000 feet in length, consisting of thirteen semicircular arches. The town, which stands at an altitude of about 740 feet above sea-level, is adorned with gardens and fine boulevards, and still contains several buildings of historical interest and many houses of the Middle Ages.' The cathedral has a very beautiful choir, with richly-painted windows of the 15th and 16th centuries. The nave, in the Pointed style, is of recent construction, as are the two towers with stone spires rising to the height of 312 feet. The white stone chiefly employed is happily contrasted with ornamental columns of black basalt. The chapel of the lyceum, which occupies the site of an ancient convent of the Visitation, contains a richly-carved mausoleum to the memory of Duke Henry of Montmorency, who was beheaded in the reign of Louis XIII. Among other objects of interest in Moulins are some remains of the old chateau of the dukes of Bourbon, and the clock tower. The library of nearly 25,000 volumes contains a manuscript Bible of the 12th century which was used at the council of Constance in 1415. There are no industries of importance, except the manufacture of wire ropes for mines, and of sulphate of barium. The population in 1881 was 21,126.

The history of Moulins does not go farther back than the 10th century, and its importance dates from the 14th, when it became the residence of the dukes of Bourbon. After the constable de Bourbon's desertion to Charles V. the town, along with Bourbonnais, fell into the hands of the king of France. In 1566 an assembly of the states-general was held in the town by Charles IX. and Catherine de Medici. Moulins has suffered frequently from epidemics and inundations, and the ducal palace was destroyed by fire in 1755.

MOULMEIN. See MAULMAIN.

MOUNTAINS. For mountains in general see GEOLOGY, vol. x. p. 370 *sq.* The more important groups of mountains are discussed under separate headings, as ALPS, HIMALAYA, ANDES, &c.

MOUNT VERNON, a city of the United States, county seat of Knox county, Ohio, and a railway junction on the Baltimore and Ohio and the Cleveland, Mount Vernon, and Columbus Railroads, 45 miles north-north-east of

Columbus. Settled in 1805, it had become a well-built flourishing place of 5249 inhabitants in 1880, engaged in various manufacturing industries.

MOURZUK, or MURZUK. See FEZZAN, vol. ix. p. 130.

MOUSE. The bright and active, though mischievous, little animal known to us by the name of Mouse and its close relative the Common Rat are the most familiar and also the most typical members of the *Murinæ*, a subfamily containing about 250 species assignable to no less than 18 distinct genera, all of which, however, are so superficially alike that one or other of the English names rat or mouse would be fairly appropriate to any of them. Together they form one, and that by far the largest and most important, of the 10 sub-families into which the Muridæ or Rat family (order *Rodentia*) are divisible. Their nearest neighbours are the Tree-mice (*Dendromyinæ*) and the Hamsters (*Cricetinæ*), from which they differ by various cranial and dental characters. Among themselves they have for the most part very strong resemblances; nearly all are of very rat-like exterior, of light and active build, with large ears, bright and well-developed eyes, long and

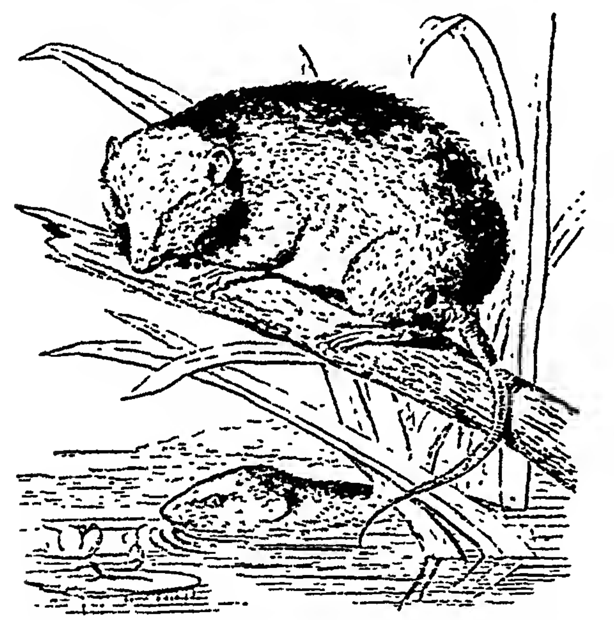

Fig. 1.—The Australian Brown-footed Rat (*Mus fuscipes*, Waterh.) (After Gould.)

scaly tails, and nearly always of dull and inconspicuous coloration, as is suitable to their usually burrowing and nocturnal habits. The more important characteristics of the group, their anatomical, cranial and dental peculiarities, have already been touched upon in the article MAMMALIA (vol. xv. p. 415 *sq.*), and therefore we may now pass to the division of the sub-family into smaller groups.

Primarily the Murinæ are divisible into the Mures, or those with their molar teeth, as in the Common Rat, and the Sigmodontes, or those with their molars, like those of the Rice-rat of America. Fig. 2 will explain this: A represents the upper molars of a Mus, and B the corresponding teeth of a Sigmodont. It will thus be seen that Mus has molars composed essentially of cusps arranged triserially—that is to say, with three series of cusps across each tooth—while in the Sigmodontes the cusps are arranged biserially in pairs along the teeth. To the first of these groups, the Mures, belong the following genera:—

A B

Fig. 2.

A. Upper molars of Mus. B Upper molars of Sigmodont.

I. *Mus*, L. Incisors narrow, not grooved. Molars small, their structure as shown in fig. 2, A. Incisive foramina long. Coronoid process of lower jaw well developed. Eyes and ears large. Fur soft, though sometimes mixed with spines; pollex with a short nail instead of a claw. No cheek-pouches. Tail long, nearly naked, with rings of overlapping scales.

This, the typical genus of the family, is by far the largest of the order, and indeed of the whole class Mammalia, containing not less than 120 species spread over the whole of the Old World with the exception of Madagascar. Of these, about 30 belong to what is known as the Palæarctic zoological region, 40 to the Oriental, 30 to the Ethiopian, and 20 to the Australian, the number of species being on the whole much more considerable in tropical than in temperate regions, while but very few are found where the climate is excessively cold. It is an interesting fact in connexion with climate that many of the species living in hot countries have their fur more or less mixed with flattened spines, and that these spines appear to be shed during the winter and to be replaced by hairs, the latter naturally affording a warmer covering for the animal than the former.

The most important characters that have been used for the determination of the various species of *Mus* are the size and proportions of the body, limbs, ears, and tail, the number of mammæ, which ranges from 6 to 20, and various more or less important differences in the shape and proportions of the skull and teeth. Of the numerous species the following are those most worthy of note:—

Mus decumanus, Pall., the Common Brown or Norway Rat, distinguished by its large size, brownish grey colour, short tail and ears, powerful skull, and the possession of from 10 to 12 mammæ. It is extremely fierce and cunning, and easily overcomes in the struggle for existence all the other allied species with which it comes in contact. Its original home would seem to have been some part of Central Asia, an indigenous species recently described from China, *M. humiliatus*, being in fact so extremely like it that in all probability the latter is the original race from which it has sprung. Thence it has spread to all parts of the world, driving out the house-haunting species everywhere, as it has in England all but exterminated the next species.

M. rattus, L., the old English Black Rat, readily distinguishable from the Brown Rat by its smaller size, longer ears and tail, and glossy black colour. It shares the roving habits of *M. decumanus*, frequenting ships, and from them passing to the land in various parts of the world. On this account it, or its tropical representative *M. alexandrinus*, Geof., is extremely common in many places to which *M. decumanus* has not yet penetrated, for instance in South America, where it has had only the far less highly-organized Sigmodontes to compete with, and where it has therefore gained a firm footing. It is extremely interesting to observe that this long-tailed rat, originally a native of India, would seem to have first penetrated to all parts of the world and to have overcome and nearly or quite exterminated the indigenous rats, and that then *M. decumanus*, a more recent and powerful development of the House-rat type, has followed, and in its turn has overcome and nearly exterminated it.

M. musculus, Linn., the Common House-mouse, is, like the last species, originally a native of India, whence it has spread to all the inhabited parts of the globe. Its habits and appearance are too well known to need any description.

M. sylvaticus, L, the Wood or Long-tailed Field-mouse, is a species very common in many parts of England, often taking to barns and outhouses for shelter during the winter. It is of about the same size and proportions as *M. musculus*, but of a bright reddish grey colour, with a pure white belly.

M. minutus, Pall., the Harvest-mouse, is the smallest of the European mice, seldom exceeding 2½ or 3 inches in length. It is of a yellowish red colour, with comparatively short ears and tail. It lives entirely away from houses, commonly taking up its abode in wheat or hay fields, where it builds a round grass nest about the size of a cricket-ball, in which it brings up its young.

These five English species may be taken as types of the 120 species of *Mus*. None are much larger than *M. decumanus* or smaller than *M. minutus*, and they all have habits generally similar to those of one or other of the English species, although there are some which either live in trees like squirrels, or in the water like the English Water-voles, among which latter is the species shown in fig. 1, *M. fuscipes*, Waterh, the Brown-footed Rat of western and southern Australia.

II. *Nesokia*, like *Mus*, but with the incisors and molars very much broader, and the transverse laminæ of the latter more clearly defined.

This genus, so closely allied to *Mus* as to be barely worthy of separation, contains five or six species of clumsily-built rats spread over southern Asia from Palestine to Formosa, and from Cashmere to Ceylon. The most noteworthy member of the group is the Great Bandicoot or Pig-rat of the continent of India (*N. bandicota*, Bechs.), the largest of all the rat tribe, often considerably exceeding a foot in length. The other species vary in size between this and a brown rat. *N. bengalensis*, Gr., the common Field-rat of

India, has no less than eighteen mammæ, nearly the largest number found among the Muridæ.

III. *Golunda*, Gray, like *Mus*, but with a distinct groove down the front of the upper incisors. There are only two species, one from western India, and the other from eastern Africa.

IV. *Uromys*, Peters., differs from *Mus* in having the scales of the tail not overlapping, but set edge to edge, so as to form a sort of mosaic work. There are about six species of *Uromys*, spread over the northern part of the Australian region from the Aru Islands to Queensland.

V. *Hapalotis*, Licht. Hind-limbs elongated. Incisive foramina very large. No coronoid process to the lower jaw. This genus is confined to Australia, where there are about fifteen species known. They are pretty little animals, with long ears and tail, and in many respects resemble the Jerboas, whose place they seem to take on the sandy Australian deserts.

VI. *Mastacomys*, Thomas, like *Mus*, but with the molars remarkably broadened, and with only four mammæ. The single species in the genus is as yet only known from Tasmania, though it has been found fossil in New South Wales; it is somewhat similar in size and general appearance to the English Water-vole, but has much longer and softer fur.

VII. *Acanthomys*, Less. Fur almost entirely composed of flattened spines. Coronoid process very small. There are six species of Spiny-mice known, all of about the size of the Common Mouse. They are found in Syria, Palestine, and eastern Africa as far south as Mozambique.

VIII. *Echinothrix*, Gray, a very remarkable rat with an extremely elongated muzzle, all the bones of the face being much produced. The incisors are faintly grooved. The only species is *E. leucura*, an animal of about the size of the Common Rat, with its fur thickly mixed with spines. It is found in Celebes.

The remaining genera belong to the Sigmodontes; they are rather more numerous than those of the Mures, but, on the whole, present somewhat less strongly marked generic differences.

IX. *Hypogeomys*, Grand., a very peculiar form of large size, with long ears, feet, and tail. There is only one species, *H. antimena*, a fawn-coloured rat about 9 inches long.

X. *Nesomys*, Peters., contains two species of long-haired rats, more or less rufous in colour, about the size of the House-rat.

XI. *Brachytarsomys*, Günther, contains only *B. albicauda*, a pretty velvety-haired fawn-coloured rat, with short feet and a long tail.

XII. *Hallomys*, Jent. The only species, *H. audeberti*, is very like a *Nesomys*, but has much longer hind-feet. This and the last three genera are confined to Madagascar.

XIII. *Hesperomys*, Waterh. Molar structure as shown in fig. 2, B. The *Mus* of the New World, containing the great mass of the rats and mice of America, and having no very special generic characters common to all its members. This large genus is composed of at least seventy distinct species spread over all America from Canada to Cape Horn, of which none are quite as large as *Mus decumanus*, while several are considerably smaller than *Mus musculus*. They have been split up into ten sub-genera, of which perhaps the best marked is *Rhipidomys*, a small group containing about ten species, remarkably like Dormice in their habits and general appearance, having soft woolly fur and long hairy tails, and living entirely in trees, bushes, or in the roofs of houses. The other *Hesperomys* are all terrestrial in their habits, much as the Old-World rats and mice are. One only, *H. spinosus*, a native of Peru, has as yet been found with spines in its fur,—a rather remarkable circumstance when we remember how many of the tropical species of the allied genus *Mus* have more or less spiny fur.

XIV. *Holochilus*, Brandt, like *Hesperomys*, but with the third upper molars proportionately larger and the skull more stoutly built. This genus, confined to Brazil, contains about six species, some of which are the largest indigenous rats of America. Two species are aquatic in their habits, and have therefore developed short webs between the toes of their hind-feet.

XV. *Sigmodon*, Say and Ord, differs from *Hesperomys* in the pattern of the molar teeth. It contains one species only, the Rice-rat, *S. hispidus*, which ranges from the United States to Ecuador.

XVI. and XVII. *Reithrodon*, Waterh., and *Ochetodon*, Coues., more or less like *Hesperomys*, but with grooved upper incisors. The first of these is a South-American genus, and contains four rat-like species, one from Venezuela and the other three from Patagonia. The second consists of three North American mice, of about the size and proportions of the English Wood-mouse, *Mus sylvaticus*.

XVIII. *Neotoma*, Say and Ord, a peculiar North-American group, in which the teeth have the prismatic appearance of those of the *Arvicolæ* (see VOLE). There are four species known as "Wood-rats," all of about the size of *Mus decumanus*, one of them, *N. cinerea*, having a tail almost as bushy as a Squirrel's; the other three with ordinary scaly rat-like tails.

From the ranges of the genera given above it will be seen that all the first group, the Mures, are confined to the Old World, and that of the Sigmodontes four genera are found in Madagascar and the rest in America, thus giving us a very remarkable instance of the peculiar affinity that the fauna of Madagascar has with that of the New World. This affinity is usually explained by the fact that those animals which show it belong as a rule to groups formerly distributed over both the Old and New Worlds, and that since the isolation of Madagascar these, owing to the competition of more highly-organized forms, have been exterminated or strongly modified throughout the continents of the eastern hemisphere, while in the western they have been preserved to the present time. Thus in the present case it seems probable that the original ancestors of the *Murinæ*, if not indeed of the whole family Muridæ, were Sigmodontes having molars with their cusps biserially arranged,[1] and that these, being less powerful in the struggle for existence, as is shown by the manner in which roving members of the Mures rapidly multiply at the expense of the indigenous Sigmodontes of any place they may be introduced into, have gradually succumbed to the more recently developed Mures wherever the latter were able to penetrate,—Madagascar having previously become an island, and therefore inaccessible to them. Other groups, however, also probably descendants of Sigmodont Muridæ, have become so strongly modified either as to structure or habits as to have been able to avoid the rivalry of the Mures, and thus to exist side by side with the latter; such probably are the Hamsters (*Cricetus*) and the Voles (*Arvicola*), both of which have modifications of the biserial arrangement of the molars. As to the *Murines* from Australia—a region isolated from the rest of the world far earlier than Madagascar—with their very various degrees of specialization, it seems probable, as Mr Wallace has suggested,[2] that from very early times individual rats and mice have drifted on floating trees and other objects from island to island along the Indian archipelago down to Australia, and that the descendants of the earliest arrivals have become the most modified, and that others have been continually joining them, until we get the present state of affairs, namely, one or two genera very markedly different from Mus, others but slightly different, and finally numerous species not generically separable from the European and Asiatic rats and mice.

(O. T.)

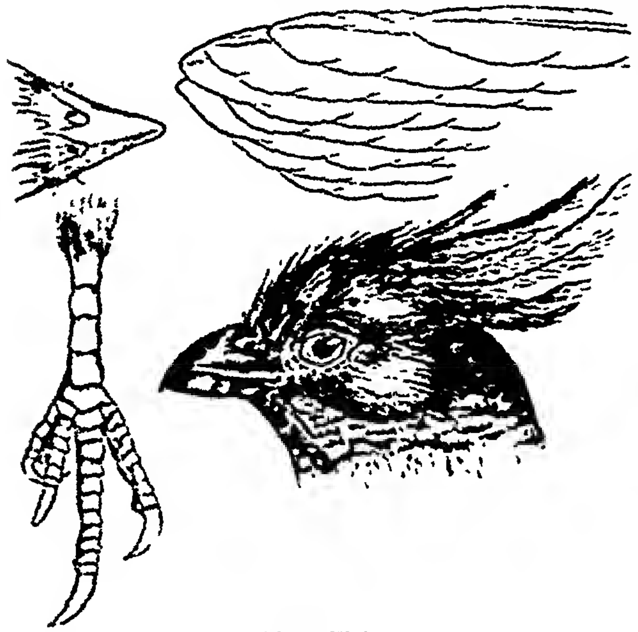
MOUSE-BIRD (Dutch *Muisvogel*), the name by which in Cape Colony and Natal the members of the genus *Colius*[3] of Brisson are known—partly, it would seem, from their general coloration, but more probably from their singular habit of creeping along the boughs of trees with the whole tarsus applied to the branch. By the earlier systematists, who had few opportunities of examining the internal structure of exotic forms, *Colius* was placed among the *Fringillidæ*; but nearly all travellers who had seen one or another species of it in life demurred to that view. Still its position was doubtful till Dr Murie, in an elaborate treatise on its osteology (*Ibis*, 1872, pp. 262-280), showed that it was no Passerine, and subsequently (*Ibis*, 1873, p. 190) proposed *Pamprodactylæ* as the name of the group of which the Family *Coliidæ* is the sole type—this word being coined to indicate the obvious character of all the toes being ordinarily directed forwards, but by no means the only peculiar character these birds possess. A few years later most of Dr Murie's views were confirmed

[1] The teeth of the extinct genus Cricetodon from the Miocene of France and Germany are in their essential structure quite similar to those of Hesperomys.

[2] *Australasia*, p. 53, 1879.

[3] Some other generic divisions have been suggested, but on grounds so slender as hardly to merit consideration.

by Garrod (*Proc. Zool. Society*, 1876, pp. 416-419), who added considerably to our knowledge of the general anatomy of the Family, which he considered to be related on the one hand to the *Picidæ*, and on the other to the *Alcedinidæ* (see KINGFISHER, vol. xiv. p. 81) and *Bucerotidæ* (see HORNBILL, vol. xii. p. 169). The *Coliidæ* are small birds, with a



Mouse-Bird.

rather Finch-like bill, a more or less crested head, a very long tail, and generally of a dun or slate-coloured plumage that sometimes brightens into blue or is pleasingly diversified with white or chestnut. They feed almost wholly on fruits, but occasionally take insects, in quest of which they pass in bands of fifteen or twenty from tree to tree, and hang in all attitudes from the branches as they feed. It is even said that they sleep suspended by their powerful and versatile toes. Seven species are believed to exist, all belonging to the Ethiopian Region (of which the Family is one of the most characteristic), and ranging from Abyssinia southwards. Three species inhabit Cape Colony. (A. N.)

MOVERS, FRANZ KARL (1806-1856), a German Orientalist, was born at Koesfeld 17th July 1806, studied at Münster, was consecrated priest in 1829, and was professor in the Catholic theological faculty at Breslau from 1839 to his death on 28th September 1856. He was one of the most learned Catholics of Germany, and his elaborate work on Phœnicia[1] attained a high and in some respects an exaggerated reputation. It is a monument of great industry but of little judgment, and the progress of epigraphic studies has superseded much of the author's material. The first volume in particular, which deals with the religion of the Phœnicians, may be viewed as quite out of date. Movers himself modified some of his views in his article "Phönizien" in Ersch and Gruber's *Encyklopädie*. Of his other writings two Biblical studies were of some importance, viz., his *Kritische Untersuchungen über die ATliche Chronik* (1834) and Latin essay on the two recensions of the text of Jeremiah (1837).

MOZAMBIQUE, a colonial province of Portugal, extending for about 1200 miles along the east coast of Africa from Cape Delgado (10° 41′ S. lat.) to Lorenzo Marques on the south side of Delagoa Bay (25° 58′ S. lat.). On paper it forms an imposing territory of at least 38,000 square miles without any definite limit towards the interior; but in reality it consists of a few settlements and military posts feebly authoritative over the surrounding tribes. The Portuguese divide the province into the military districts of Mozambique, Cape Delgado, Angoche, Quilimane, Tete, Sofala, and Lorenzo Marques, with the presidential territory of Bazaruto. The small coral island of Mozambique, which gives its name to the province and contains the provincial capital, lies in 15° S. lat., about 3 miles off the coast of the peninsula Mossuril. It is defended by three forts, of which the principal, St Sebastian, is built entirely of stone brought from Portugal in 1510. The streets of the town (properly St Sebastian of Mozambique) are narrow and crooked, and the stone-built flat-roofed houses are for the most part dull and lifeless in spite of their being washed with pink, brown, and white. Its principal buildings are the palace of the governor-general, formerly a Jesuit college, the custom-house, the hospital, and three churches. The population includes, besides Portuguese and Africans, Banyans, Parsees, and Arabs. The district of Cape Delgado includes the archipelago of the Querimba Islands, and on the opposite mainland Mucimba, Pangane, Lumbo, Quissanga, Montepes, Arimba, besides the colony of Europeans founded in 1857 on the Bay of Pemba. The chief town is Ibo, with over 2000 inhabitants, situated on the island of the same name. Of the twenty-eight islands some are nearly deserted, although both their climate and that of the opposite coast is good. Ibo has a considerable trade,—the exports being sesame, calumba root, oil-seeds, ivory, and wax. Turtle fishing is carried on; but little has been done to develop the agricultural capabilities of the district. The district of Angoche extends nominally as far south as the Quirimbo river, and includes the Angoche and Primeira islands and a small settlement on the Angoche river. The trade is very limited. The district of Quilimane is the centre of the commerce of the Zambesi, and the town ranks next to Mozambique as a port. Near the village of St Marçal de Sena, the headquarters of the sub-military government of Sena, there are said to be very rich gold mines. Tete, to the north-west of Sena, is situated in the centre of an immense coal-basin. It includes a number of settlements on the Zambesi reaching as far as Zumbo, where a great native fair is held. The chief town is St Thiajo Major, about 250 miles from the mouth of the Zambesi. The climate is genial, and the soil is specially suitable for wheat, maize, tobacco, cotton, and sugar-cane. The chief town of the Sofala district is Sofala on the island of Chiloane in the estuary of the Sofala river. It was the original capital of the colony, and still possesses a good harbour, which, however, is not always easily accessible, and requires good piloting. The district is rich in gold mines, and is supposed by some to be the Ophir with which King Solomon traded. Inhambane, opposite Gasa, is very much encroached upon by the Zulu tribes. The natural products are similar to those in the Zambesi valley. A species of oil-plant is very abundant, as well as amber and sarsaparilla. The district of Lorenzo Marques is almost wholly confined to the town of that name (*q.v.*). The archipelago of Bazaruto comprises the islands of Bazaruto, Benguerua, Xegine, Bango, and Santa Carolina. The soil and climate are both excellent, and there are important pearl fisheries.

Before the 12th century this portion of the east coast of Africa had been partly colonized by Arabs from the Red Sea, who were in possession of the island of Mozambique and other districts when in 1498 the island was sighted by the Portuguese. From that time the Portuguese armadas were in the habit of frequently touching this coast on their way to India, and in 1505 Albuquerque erected a stockade at the mouth of the Sofala river and established the first Portuguese settlement under the name of the captaincy of Sofala. The fortunes of the Portuguese have been frequently chequered with disasters, and in the earlier years of their settlement they had great difficulty in withstanding successive attacks of the Kaffres, the Turks, and the Arabs. The Banyan traders began

[1] *Die Phönizier*: vol. i., *Religion* (1840); vol. ii., *Das Phönizische Alterthum* (3 parts, 1849-50-56).

to frequent the Portuguese settlements in 1687, and were succeeded by the Battias from Hindustan. From Cape Delgado to Quilimane the native race on the coast is the Makua, who, notwithstanding the presence of Arabs, Banyans, and Battias, have preserved in a remarkable degree their purity of descent, although their language has undergone considerable change. The whole of the country between the Rovuma and the Zambesi is thickly populated by branches of this race governed by numerous petty independent despots. The Makua are divided into four families or groups—the Low Makua, the Lomwe or Upper Makua, the Maua, and the Medo. The Makololo, a powerful Basuto tribe who inhabited the valley of the Zambesi, were about twenty-five years ago not only conquered but almost annihilated by the Manganja and Makua races. South of the Zambesi are the Landeens or Northern Zulus, who under Umzeila subdued Gasa, and press closely on the coast settlements of the Portuguese, which again are bounded on the south by Usibepu's land.

Natural Features and Resources.—Though the climate of the Mozambique country is subject to sudden and great alterations, the mean annual temperature is high. The cool season lasts from April to August. In the rainy season, which begins in December and sometimes continues to March, the heat when rain is not falling, which is scarcely ever, is almost insupportable. On the rivers and the coast the mangrove swamps cause fever to Europeans, but the climate is not dangerous if moderate care is taken.

The whole of the country south from the Rovuma to the Zambesi possesses naturally great fertility, the richest portion, however, being that between Angoche and Quilimane. The mountain ranges which flank Lake Shirwa are of great height and towards Quilimane extend almost to the coast. In the basin of the Zambesi the soil is fertilized by the inundations of the river, and yields abundantly with almost no labour. The low coast land of the Gasa country is almost equally fruitful. The whole region of Mozambique is intersected by numerous rivers, some of which are navigable, while at several of the estuaries there are admirable natural harbours. Ebony, the gum-copal tree, the india-rubber climber, sandal-wood, and a large number of valuable timber trees are found in the extensive forests. In the interior elephants, antelopes, and buffaloes abound, as well as lions and leopards, and the rhinoceros and hippopotamus frequent certain regions. Game in immense variety is plentiful, and the pearl and other fisheries are valuable. The mineral resources of the country are of exceptional importance. There are immense deposits of coal in the neighbourhood of the Zambesi and of Delagoa Bay, and adjoining the coalfields ironstone of the best quality is very plentiful. Malachite and copper are found in the interior, north-west of Mozambique. The gold-mines of Manica, about 120 miles west of Sofala, are supposed to be the richest on the east coast of Africa.

Industry and Commerce.—Almost nothing has been done to develop the resources of the country, and the Portuguese have scarcely carried their discoveries beyond the regions where they have settled. Journeys through the Makua country have lately been made by H. E. O'Neill and the Rev. Chauncey Maples.[1] The Zambesi valley and the districts round Lakes Nyassa and Shirwa have been explored by Kirk and Livingstone. The regions bordering on the Transvaal have been visited by Carl Mauch and St Vincent Erskine. Although a great part of the country is admirably adapted for the growth of cotton, coffee, and sugar, scarcely any attempt has been made to form plantations. The caju tree, which yields an intoxicating liquor, is, however, largely cultivated, and the cocoa-nut tree is also grown. The number of independent chiefs in the Makua country renders it almost inaccessible to traders, but ivory is sold in large quantities for the Indian market, the annual value being about £70,000. The other exports include bees-wax, corn, gums, india-rubber, and oil. The financial difficulties of the Portuguese Government have completely retarded the commercial enterprise of the settlements. The trade is almost entirely in the hands of the Banyans, who are supplied by French and Dutch houses with goods, chiefly cotton and silk cloths, brandy, wine, and old guns, which they barter for produce with the natives on the coast. The only river by which there is regular communication with the interior is the Zambesi. On the coast of Mozambique there are several native ports of call, between which and Madagascar a large surreptitious trade in slaves was carried on until 1877. With this island, and also with Zanzibar, there is a large general coasting trade. The British India Company's steamers from Zanzibar in connexion with steamers from Aden and Lisbon also call every twenty-eight days at Mozambique, and a monthly steamer from Natal calls at Delagoa Bay, Inhambane, Quilimane, and Mozambique. The general shipping trade is carried on by about 400 vessels, of which about one-half are coasters. English vessels in 1877 were said to number 79 of 30,000 tons, French 72 of 13,000 tons, Portuguese 41, Arab 19, Dutch 8, and German 9.

For the Portuguese settlements see the report by Consul Elton in *Accounts and Papers*, 1876, and L. de B., *Les Colonies Portugaises: court exposé de leur situation actuelle*, Lisbon, 1878. For the region in general see the works of the travellers referred to. (T. F. H.)

[1] See *Proc. Roy. Geog. Soc.*, 1882.

MOZARAB, Spanish *Mozárabe*, is a corruption of the Arabic *Musta'rib*, coll. *Musta'riba*, which denotes persons not Arab by race who have assimilated themselves to the Arabs. This name was applied by the Moslems in Spain to the Christian communities existing among them, in Cordova, Seville, Toledo, and other large cities, in the exercise of their own laws and religion. The ancient liturgy (see vol. xiv. p. 707) used by the Christians of Toledo, the first great body of this kind who were freed from the Moslem yoke, is commonly known as Mozarabic.

MOZART, Wolfgang Amadeus[2] (1756-1791), one of the greatest musicians the world has ever produced, was born at Salzburg, 27th January 1756. He was educated by his father, Leopold Mozart, a violinist of high repute, in the service of the archbishop of Salzburg. When only three years old he shared the harpsichord lessons of his sister Maria, five years his senior. A year later he played minuets, and composed little pieces, some of which are still preserved in Maria's music-book. Not long afterwards he attempted to write a concerto. This, his father said, was so difficult that no one could play it, whereupon Wolfgang replied that no one could be expected to play a great work like a concerto without having first diligently practised it. When five years old he performed in public, for the first time, in the hall of the university. In 1762 Leopold Mozart took Wolfgang and Maria on a musical tour, during the course of which they played before most of the sovereigns of Germany. The little "Wolferl's"[3] charming appearance and disposition endeared him to every one; and so innocent and natural were his manners that at Vienna he sprang upon the empress's lap and kissed her heartily. The emperor Francis I. sat by his side while he played, and called him his "little magician." When he slipped one day on the polished floor the arch-duchess Marie Antoinette, afterwards queen of France, lifted him up, whereupon he said, "You are very kind; when I grow up I will marry you." The favour shown to him at court was almost incredible; yet he remained as gentle and docile as ever, and so amenable to parental authority that he used to say, "Next after God comes my father." In 1763 the whole family started again. Wolferl now sang, composed, and played on the harpsichord, the organ, and the violin, winning golden opinions everywhere. At every court he visited he was loaded with caresses and presents; but the journeys were expensive, and the family terribly poor. In Paris they lodged at the Bavarian embassy, giving performances on a grand scale both there and at Versailles, where Wolferl's organ-playing was even more admired than his performance on the harpsichord. Here, also, he published his first compositions—two sets of sonatas for the harpsichord and violin.

On 10th April 1764 Leopold Mozart brought his family to England, engaging a lodging in Cecil Court, St Martin's Lane, whence he afterwards removed to Frith Street, Soho. On 27th April and 19th May Wolferl played before the royal family with immense success, accompanying the queen in a song and playing at sight anything that the king set before him. "Our treatment here," says Leopold Mozart in one of his letters, "exceeds all our previous experience. We could not believe ourselves in the presence of the king and queen of England, so friendly were their manners." Wolferl gave a public concert at the Great Room in Spring Gardens on 5th June, and on the 29th played a concerto at Ranelagh. He now made his first attempt at the composition of a symphony; published a

[2] In the baptismal register his name stands, *Joannes Chrysostomus Wolfgangus Theophilus* (Lat. *Amadeus*, Germ. *Gottlieb*).
[3] The German diminutive of Wolfgang.

third set of sonatas, dedicated to the queen; and wrote an anthem for four voices entitled *God is our Refuge*, for presentation to the British Museum.[1] In July 1764 he played at Tunbridge Wells, and soon afterwards Leopold Mozart caught a severe illness, during the continuance of which he stayed with Dr Randall in Five Fields Row, now Lower Elmry Street, Chelsea. On 12th February 1765 the children gave a concert at the Little Theatre in the Haymarket, and another on 13th May at Hickford's Room. After this they gave private performances at the Swan and Hoop Tavern, Cornhill: and on 17th September the family left England for the Hague, where they remained some time, and where in March 1766 the young composer made his first attempt at an oratorio, commanding in Holland a success as great as that he had already attained in London, and astonishing his hearers at Haarlem by performing on the then largest organ in the world. It would be impossible within the limits of a sketch like the present to follow the history of this gifted boy through all its extraordinary details. Towards the close of 1766 we find him at home in Salzburg, diligently studying Fux's *Gradus ad Parnassum*. In September 1767 he paid a second visit to Vienna, and at the suggestion of the emperor Joseph II. composed an opera buffa, *La Finta Semplice*, which, though acknowledged by the company for which it was written to be "an incomparable work," was suppressed by a miserable cabal. The archbishop of Salzburg hearing of this commanded a representation of the rejected work in his palace, and appointed the young composer his "maestro di capella." The office, however, was merely an honorary one, and, since it did not involve compulsory residence, Leopold Mozart determined to complete his son's education in Italy, to which country he himself accompanied him in December 1769.

Wolfgang, now nearly fourteen years old, was already an accomplished musician, needing experience rather than instruction, and gaining it every day. His talent was universally acknowledged. At Milan he received a commission to write an opera for the following Christmas. At Bologna he found firm friends in the venerable Padre Martini and the still more famous sopranist Farinelli. At Florence he became so tenderly attached to Thomas Linley, a boy of extraordinary promise and exactly his own age, that he parted from him with tears, which seemed almost prophetic—for Linley was drowned in England at the early age of twenty-two. Arriving in Rome on the Wednesday in Holy Week, he went at once to the Sistine Chapel to hear the celebrated *Miserere* of Gregorio Allegri, which, on returning to his hotel, he wrote down from memory note for note—a feat which created an immense sensation, for at that time the singers were forbidden to transcribe the music on pain of excommunication. In May he played at the Conservatorio della Pietà, in Naples, where the audience, attributing his power to the magical effect of a ring, insisted upon its removal from his finger. Returning to Rome towards the end of June, he was invested by the pope with the order of "The Golden Spur," of which he was made a cavaliere,[2] an honour which he prized the more highly because, not many years before, it had been conferred upon Gluck. In July he paid a second visit to Bologna, when the Accademia Filarmonica, after subjecting him to a severe examination, admitted him to the rank of "compositore," notwithstanding a statute restricting this preferment to candidates of at least twenty years old. The exercise which gained him this distinction is a four-part composition in strict counterpoint on the antiphon *Quærite primum*, written in the severe ecclesiastical style of the 16th century and abounding in points of ingenious imitation and device.[3]

In October 1770 Wolfgang and his father returned to Milan for the completion and production of the new opera. The libretto, entitled *Mitridate, Re di Ponto*, was furnished by an obscure poet from Turin, to the great disappointment of the young maestro, who had hoped to set a drama by Metastasio. The progress of the work was interrupted from time to time by the miserable intrigues which seem inseparable from the lyric stage, exacerbated in this particular case by the jealousy of the resident professors, who refused to believe either that an Italian opera could be written by a native of Germany, or that a boy of fourteen could manage the orchestra of La Scala, at that time the largest in Europe. Fortunately the detractors were effectively silenced at the first full rehearsal; and on the 26th of December Wolfgang took his seat at the harpsichord and directed his work amidst a storm of genuine applause. The success of the piece was unprecedented. It had a continuous run of twenty nights, and delighted even the most captious critics.

Wolfgang's triumph was now complete. After playing with his usual success in Turin, Verona, Venice, Padua, and other Italian cities, he returned with his father to Salzburg in March 1771, commissioned to compose a grand dramatic serenata for the approaching marriage of the archduke Ferdinand, and an opera for La Scala, to be performed during the season of 1773. The wedding took place at Milan on 21st October; and the serenata, *Ascanio in Alba*, was produced with an effect which completely eclipsed Hasse's new opera, *Ruggiero*, composed for the same festivity. The empress Maria Theresa was so delighted with it that in addition to his fee she presented Wolfgang with a watch set with diamonds and enamelled with her portrait; and Hasse, forgetful of his own defeat, generously uttered the often-quoted prophecy, "This boy will cause us all to be forgotten."[4]

During the absence of Wolfgang and his father the good archbishop of Salzburg died; and in the spring of the year 1772 Hieronymus, count of Colloredo, was elected in his stead, to the horror of all who were acquainted with his real character. The Mozart family did their best to propitiate their new lord, for whose installation Wolfgang, after his return from Milan, composed an opera, *Il Sogno di Scipione*; but the newly-elected prelate had no taste for art, and was utterly incapable of appreciating the charm of any intellectual pursuit whatever. For the present, however, things went on smoothly. In October the father and son once more visited Milan for the preparation and production of the new opera, *Lucio Silla*, which was produced at Christmas with a success quite equal to that of *Mitridate*, and ran between twenty and thirty nights. Unfortunately, however, these artistic triumphs were far from profitable in their pecuniary aspect. The family grew poorer and poorer; and the archbishop Hieronymus was not the man to rescue them from penury.

In the meantime Wolfgang continued to produce new works with incredible rapidity. In 1775 he composed an opera for Munich, *La Finta Giardiniera*, produced on 13th January. In the following March he set to music Metastasio's dramatic cantata, *Il Re Pastore*. Concertos, masses, symphonies, sonatas, and other important works, both vocal and instrumental, followed each other without a pause. And this fertility of invention, instead of ex-

[1] The original autograph of this is now numbered "Select case C, 21, d."

[2] *Auratæ militiæ eques*

[3] An exact copy of this most interesting production, transcribed from the original autograph still preserved among the archives of the Accademia, will be found in the appendix to Holmes's *Life of Mozart* (London, 1845).

[4] "Questo ragazzo ci farà dimenticar tutti."

hausting his genius, seemed only to stimulate it to still more indefatigable exertions. But the pecuniary return was so inconsiderable that in 1777 Leopold Mozart asked the archbishop for leave of absence for the purpose of making a professional tour. This was refused on the ground of the prelate's dislike to "that system of begging." Wolfgang then requested permission to resign his appointment, which was only an honorary one, for the purpose of making the tour with his mother. The archbishop was furious; but the plan was carried out at last, and on the 23d September the mother and son started for Munich. The results were not encouraging. Leopold hoped that his son, now twenty-one years old, might obtain some profitable court appointment; but in this he was disappointed. And, worse still, poor Wolfgang fell in love at Mannheim with a promising young vocalist named Aloysia Weber, whose father, the prompter of the theatre, was very nearly penniless. On hearing of this Leopold ordered his wife and son to start instantly for Paris, where they arrived on 23d March 1778. Wolfgang's usual success, however, seemed on this occasion to have deserted him. His reception was a cold one; and, to add to his misery, his mother fell seriously ill. He wrote home in unspeakable distress; but the worst had not yet come. On 3d July the parent to whom he was so tenderly attached expired in his arms. Reduced almost to despair by this new trouble, he left Paris in September, rested for a while on his way home in Mannheim and Munich, was received by Aloysia Weber with coldness almost amounting to contempt; and in June 1779 he returned to Salzburg, hoping against hope that he might make some better terms with the archbishop, who relented so far as to attach a salary of 500 florins (about £50) to his "concertmeister's" appointment, with leave of absence in case he should be engaged to write an opera elsewhere.

Two years later the desired opportunity presented itself. He was engaged to compose an opera for Munich for the carnival of 1781. The libretto was furnished by the abbate Varesco, court chaplain at Salzburg, a truly sympathetic collaborateur. On 29th January 1781 the work was produced under the title of *Idomeneo, Re di Creta* with triumphant success, and thenceforth Mozart's position as an artist was assured; for this was not only the finest work he had ever written but incontestably the finest opera that had ever yet been placed upon the stage in any age or country. It marked an era in the history of art, and raised the lyric drama to a level till then unknown.

And now the archbishop's character exhibited itself in its true colours. Art for its own sake he utterly disdained; but it flattered his vanity to retain a famous artist in his service with the power of insulting him at will. On hearing of the success of *Idomeneo* he instantly summoned the composer to Vienna, where he was spending the season. Mozart lost not a moment in presenting himself, but he soon found his position intolerable. That he should be condemned to dine with his patron's servants was the fault of the age, but the open disrespect with which the lowest menials treated him was due to the archbishop's example. Though received as an honoured guest in the houses of the *haute noblesse* of Vienna, he was uniformly addressed by the archbishop in the third person singular, a form used in Germany to express the utmost possible contempt. His salary was reduced from 500 to 400 florins, he was left to pay his own travelling expenses, and he was not permitted to add to his means by giving a concert on his own account or to play anywhere but at the archiepiscopal palace; indeed it was only at the instance of a large number of the nobility that he obtained leave to take part, gratuitously, in a concert given for the poor. Archbishop Hieronymus was hated at court, and most of all by the emperor Joseph, who, on retiring to Laxenburg for the summer, did not place his name on the list of invited guests. This offended him so deeply that he left Vienna in disgust. The household were sent on to Salzburg, but Mozart was left to find lodgings at his own expense. Thereupon he sent in his resignation; and for this act of contumacy was insulted by the archbishop in terms too vulgar for translation. He persevered, however, in his resolution, taking lodgings in a house rented by his old friends the Webers, and vainly hoping for pupils, since Vienna at this season was perfectly empty. Happily he had a sincere though not a generous well-wisher in the emperor, and a firm friend in the archduke Maximilian, who, in common with many noblemen of rank, were disgusted with the archbishop's behaviour. By the emperor's command he wrote a German opera, *Die Entführung aus dem Serail*, which on 16th July 1782 was received with acclamation, and not long afterwards was performed with equal success at Prague. This great work raised the national "singspiel" to a level commensurate with that which *Idomeneo* had already attained for the Italian "opera seria." Gluck's great reform of the lyric drama (based, not, as is sometimes erroneously supposed, on new principles invented by himself, but on those enunciated by Peri and his associates as early as the year 1600, when the first Italian opera was produced at Florence) had already attracted immense attention in Paris, and was everywhere producing good fruit. It was impossible that it should do otherwise, for it was founded on pure dramatic truth. But what Gluck worked out in obedience to a carefully-elaborated theory Mozart effected by simple force of natural dramatic instinct. Moreover, with all his love for graceful melody, his power of expression, and dramatic force, Gluck was not great as a constructive musician. On the other hand, the erudition which in 1770 had won Mozart's diploma from the Accademia at Bologna was no mere rusty exhibition of scholastic pedantry. It enabled him to cast his music into symmetrical and well-considered form, without sacrificing the demands of dramatic consistency; to enchant the unlearned hearer with an endless flow of melody, while satisfying the cultivated musician with the most ingenious part-writing that had ever been imagined in connexion with the stage; to construct the grand finales that have made his operas the finest in the world;—and all this with equal reverence for the claims of legitimate art on the one side and those of passionate expression on the other. For the finales are no dead forms, but living scenes developing the action of the drama. And the impassioned utterances are no poor passages of "sound and fury, signifying nothing," but well-constructed music, shapely and beautiful,—music which Gluck himself, with all his genius, could no more hope to rival than Hasse could hope to rival the choruses in *Israel in Egypt*. For Gluck, though his taste was as refined and his intellect as highly cultivated as Mozart's, was, as Handel justly observed, no contrapuntist; and works like Mozart's needed an intimate acquaintance with the mysteries of counterpoint, no less than purity of taste and intellectual culture. And so it comes to pass that Mozart's operas still retain a stronger hold upon the affections, both of the general public and the initiated worshipper of art, than any other dramatic music that has ever been written.

The next great event in Mozart's life was a disastrous one. Though Aloysia Weber had long since rejected him, his renewed intimacy with the family led to a most unfortunate marriage with her younger sister, Constance, a woman who, neither his equal in intellect nor his superior in prudence, added little to the happiness of his life and less than nothing to its prosperity. The wedding took place at St Stephen's on 16th August 1782. By the end of the year the thriftless pair were deeply in debt. Mozart

composed incessantly, played at numberless concerts, and was in greater favour than ever at court and with the nobility; but to the last day of his life his purse was empty. He had, however, many kind friends, not the least affectionate of whom was the veteran Haydn, who was sincerely attached to him. With Gluck he was on terms of courteous intercourse only. Salieri detested him, and made no secret of his dislike.

Mozart's next dramatic venture was a German singspiel in one act, *Der Schauspieldirektor*, produced at Schönbrunn, 7th February 1786. Not quite three months later, on 1st May, he produced his marvellous *Le Nozze di Figaro*, the libretto for which was adapted from Beaumarchais by the abbé Da Ponte. The reception of this magnificent work was enthusiastic. But Vienna was a hotbed of intrigue. Everything that could be done by jealous plotters to mar the composer's success was done, and that so effectively that Mozart declared he would never bring out another opera in the city which treated him so meanly. Fortunately, *Figaro*, like *Die Entführung*, was repeated with brilliant success at Prague. Mozart went there to hear it, and received a commission to write an opera for the next season, with a fee of 100 ducats. Da Ponte furnished a libretto, founded on Tirso de Molina's tale, *El Convidado de Piedra*, and entitled *Il Don Giovanni*. By 28th October 1787 the whole was ready with the exception of the overture, not a note of which was written on the evening before the performance. This circumstance has led to the idea that it was composed in haste, but it is certain that Mozart knew it all by heart and transcribed it during the night from memory, while his wife told fairy tales to keep him awake. The opera was produced on 29th October with extraordinary effect, and the overture, though played without rehearsal, was as successful as the rest of the music.[1] Yet, when reproduced in Vienna, *Don Giovanni* pleased less than Salieri's comparatively worthless *Tarare*.

On returning to Vienna Mozart was appointed kammercompositor to the emperor with a salary of 800 gulden (£80). He also conducted Baron van Swieten's concerts, and composed great quantities both of sacred and secular music, but continued miserably poor, while his wife had become a confirmed invalid. In April 1789 he accompanied Prince Lichnowski to Berlin, where King Frederick William II. offered him the post of "kapellmeister" with a salary of 3000 thalers (£450). Though most unwilling to quit the emperor's service, he informed him of the offer and requested leave to resign his appointment in Vienna. "Are you going to desert me, then?" asked the emperor; and Mozart, wounded by the reproach, remained to starve. The emperor now commissioned Mozart to compose another Italian opera, which was produced 26th January 1790 under the title of *Così fan tutte*. Though the libretto by Da Ponte was too stupid for criticism, the music was delicious, and the opera would probably have had a long run but for the emperor's death on 7th February. The new emperor, Leopold II., was elected at Frankfort in September, and Mozart went thither in the hope of giving some concerts, but he was obliged to sell his plate to pay the expenses of the journey, and returned in December. In March 1791 Mozart consented to write a German opera upon an entirely new plan for Schikaneder, the manager of the little theatre in the Wieden suburb. The piece was addressed especially to the Freemasons and contained ceaseless allusions both in the words and music to the secrets of the brotherhood. Deeply interested in the affairs of a body of which he was himself a member,[2] Mozart excelled himself in this new work, for the overture of which he invented a new art-form, that of the "symphonic fugue." He was rewarded for his labours by a brilliant artistic success, but Schikaneder alone reaped the financial benefit of the speculation.

Before the completion of *Die Zauberflöte* a stranger called on Mozart, requesting him to compose a *Requiem* and offering to pay for it in advance. He began the work under the influence of superstitious fear, believing that the messenger had been sent from the other world to forewarn him of his own approaching death. Meanwhile he received a commission to compose an opera, *La Clemenza di Tito*, for the coronation of the emperor at Prague. He worked incessantly, and far beyond his strength. The coronation took place on 6th September, and its splendours threw the opera very much into the shade. *Die Zauberflote* was produced on 30th September and had a splendid run. But the *Requiem* still remained unfinished; the stranger therefore made another appointment, paying a further sum in advance. Mozart worked at it unremittingly, hoping to make it his greatest work. His sacred music, though less florid than Haydn's, was even more voluptuously beautiful,—perfect in its kind, though showing no trace of the stern grandeur of Handel, or the devotional purity of Palestrina. In the *Requiem* he surpassed himself, but he was not permitted to finish it. When the stranger called the third time the composer was no more. The score of the *Requiem* was completed by Süssmayer, whose task, simplified by the instructions he had received from Mozart on his death-bed, was a purely mechanical one. It is now known that the work was commissioned by Count Walsegg, who wished to perform it as his own.

Mozart died 5th December 1791, apparently from fever, though he believed himself poisoned. His funeral was a disgrace to the court, the emperor, the public, society itself. On the afternoon of the 6th his body was hurried to a pauper's grave; and because it rained Van Swieten, Süssmayer, and three other "friends" turned back and left him to be carried to his last long home alone.

Mozart's compositions, whether for the church, the theatre, or the concert-room, are pervaded by an individuality of style which can never be mistaken. Of the truthful expression of his dramatic music we have already spoken Apart from its innate beauty, its artistic strength consists in its perfect adaptation to the situation for which it is designed. The same great quality characterizes his symphonies, his concertos, and his sonatas for the pianoforte and other solo instruments. Each work presents us with the logical and consistent development of a noble idea, of which we never lose sight for a moment. No trace of indecision or inconsequence is discernible in any part of the composition. Every note is fitted into its place with a definite purpose, and takes its share in the arrangement of the design with a certainty which leaves no doubt as to the object for which it was introduced. The result of this well-considered symmetry is a degree of technical perfection which no composer, ancient or modern, has ever surpassed But technical perfection does but supply the body into which true genius alone can breathe the living soul And here it is that we must look for the inexpressible charm which Mozart's music never fails to exercise upon all who hear it. Its boundless wealth of melody is governed by a refinement of taste which excludes every subject, every phrase, every minutest cadence which is not both beautiful in itself and capable of enhancing the beauty of its fellow-phrases. Mozart himself has left us, in a letter to Baron V——, a memorable description of the loving care he exercised in the selection of his charming phrases. He tells us that his ideas flowed best when he was alone and feeling cheerful. Having once conceived an idea he subjected it to a process of mental elaboration which continued until the composition was complete. Then, and not till then, he committed it to paper; and hence it was that he was able to write out the overture to *Don Giovanni* on the day of its first performance.

Von Kochel's *Chronologisch-thematisches Verzeichniss*, 1862, contains a complete list of Mozart's works (W. S. R.)

MOZDOK, a Russian town in the government of the Caucasus and province of Stavropol, lies on the left bank of the Terek, 465 feet above the level of the sea, in 43° 41′ N. lat. and 44° 39′ E. long., 58 miles north of Vladi-

[1] Michael Kelly, in his *Reminiscences*, has left a delightful account of the circumstances.

[2] Freemasonry did not at that time involve the censure of the Catholic Church, or Mozart would certainly have renounced it

kavkas, with which it is connected by a highroad, and $36\frac{1}{2}$ miles east of the Prochladnaya station on the Rostoff-Vladikavkas railway. Built on the site of an oak-wood (*moz, noz*, thick or dark, *dok*, wood, in Kabardine) in 1763 by Kogorko-Kontchukin, prince of Kabarda, it soon became an important point in the Russian line towards the Caucasus, and was fortified with earthen rampart and ditch. In 1840 it was attacked by Schamyl and 5000 mountaineers. The population (8760 in 1863) numbered 11,008 in 1877, 52 per cent. being "Orthodox" (with very few sectaries), 29 per cent. Armenians, 15 per cent. Mohammedans, and 2 per cent. Catholics. Gardening and agriculture are the main means of subsistence, scarcely fifty individuals living by trade. The melons and water-melons of Mozdok are widely famed; and, though vine-growing was only begun in 1873, by 1876 there was a production of 563 casks of wine or 1,416,000 bottles. An oil-mill, tanneries, and soapworks are among the industrial establishments. Three fairs are held in the year.

MOZLEY, James Bowling (1813-1878), English theologian, a native of Lincolnshire, born in 1813, was educated at Oriel College, Oxford, where he graduated in 1834. He was appointed to a fellowship at Magdalen College in 1837, was ordained deacon in 1838, priest in 1844, and became vicar of Shoreham in 1856. In 1869 he became canon of Worcester, and in 1871 regius professor of divinity at Oxford. He died at Shoreham on 4th January 1878.

He wrote *A Treatise on the Augustinian Doctrine of Predestination* (1855); *The Primitive Doctrine of Baptismal Regeneration* (1856); *A Review of the Baptismal Controversy* (1863); *Subscription to the Articles: a Letter* (1863); *Lectures on Miracles*, being the Bampton Lectures for 1865; *University Sermons*, 1876; and a volume on the Old Testament entitled *Ruling Ideas in Early Ages* (1877). In all these works he has advocated his views, those of a strongly-convinced English High-Churchman, with uprightness, learning, acuteness, and sagacity.

MTSENSK (popularly called *Amchensk*), a district town of Russia, situated in the government of Orel on the navigable Zusha river, 17 miles from its junction with the Oka, on the Moscow and Kursk railway, 32 miles to the north-east of Orel. It is mentioned in the Russian chronicles as early as 1147 as a town of the principality of Tchernigoff. Many battles were fought for its possession, and the plains around are dotted with grave-mounds. Though protected by a fort which occupied a strong position, the town was taken and plundered several times by the Tatars, the Russians, the Poles, and the Lithuanians. From 1320 to 1530 it was under the rule of Lithuania; in the latter year it was taken by Russia, and became one of her chief strongholds against the raids of the Tatars. It is now an important centre for trade in grain, hemp, hemp-seed oil, tobacco, and wine-spirit, shipped on the Zusha, Oka, and Volga to and from Moscow, Nijni-Novgorod, and St Petersburg, or forwarded by rail to Moscow, Libau, and Riga. Population, 15,000.

MUCILAGE, a term which denotes a viscid or glutinous mixture of water and any gummy vegetable substance. The principal sources of mucilaginous matters are enumerated under Gum (vol. xi. p. 276). A mucilage indicates a physical condition or property rather than any definite chemical constitution, and consequently it may possess various characters, but as a rule the term is restricted to the bodies which swell into a kind of jelly with water, having the insoluble gum bassorin as their principal constituent. Such mucilages are useful in medicine as emollients and demulcents, and in the arts as thickeners (in calico-printing, dyeing, &c.). A remarkable variety of mucilage has been recently obtained by Stanford of Glasgow from certain of the commoner kinds of *Algæ*, and called from its source algin. The *Laminariæ* yield it in abundance and in a comparatively colourless condition; it is also found in *Fuci*, but darkly coloured. It is a substance of considerable thickening character, and has the peculiar property of gelatizing on the addition of a dilute mineral acid. A solution containing only 2 per cent. of algin when thus treated sets into a solid jelly. Alcohol has the same effect upon it. It is extracted from the plants by sodium carbonate, and as it can be obtained in large quantity it may become useful in the dressing of fabrics, or as a thickener in calico-printing.

MUGGLETON, Lodowick (1610-1698), the founder of the sect of the Muggletonians, was born in Bishopsgate Street, London, about the year 1610. His father was a farrier, but he himself was bred to be a tailor. In 1651 he began to have revelations by "a motional voice," and to proclaim himself and a brother tailor, John Reeve, as the two witnesses mentioned in the Apocalypse, and as the "true prophets of the only high, immortal, glorious God, Jesus Christ." An exposition of their doctrines was published in 1656 under the title of *The Divine Looking-Glass*. Among other views (besides the doctrine of the divine mission of the authors) this work taught that the distinction of the three persons in the Trinity is merely nominal, that God has a real human body, and that He left Elijah as His vicegerent in heaven when He Himself descended to die on the cross. These opinions, strange to say, gained considerable currency, and naturally also called forth much opposition. William Penn's book, *The New Witnesses proved Old Heretics* (1672), was directed against them, and in 1676 Muggleton was tried at the Old Bailey and convicted of blasphemy. Reeve died in 1658, but Muggleton survived till 1698. His collected works, including the posthumous *Acts of the Witnesses*, were published in 1756; and in 1832 some sixty Muggletonians subscribed to bring out a new edition of *The Works of J. Reeve and L. Muggleton* (in 3 vols. 4to). Even as late as 1846 *The Divine Looking-Glass* was reprinted by members of the sect, which is now, however, believed to be extinct.

MÜHLHAUSEN, a busy manufacturing town of Thuringia in the district of Erfurt, Prussia, is situated on the right bank of the Unstrut, 25 miles to the north-west of Gotha. It consists of a new and an old town surrounded by five suburbs, and with its numerous old churches and towers presents a quaint and picturesque appearance. The most interesting churches are those of the Blessed Virgin and St Blasius, dating respectively from the 14th and from the 12th century; the town-house is also a fine mediæval structure. Mühlhausen contains a gymnasium, a "real school," a theatre, an orphanage, and two hospitals. Its chief industries are the spinning and weaving of woollens and cottons, in which about 50,000 spindles and 3000 looms are employed; but a list of its other manufactures includes the most varied articles, such as needles, machinery, cigars, soap, hosiery, and shoes. There are also numerous large establishments for dyeing, tanning, lime-burning, iron-making, brewing, and the preparation of liqueurs. The active trade of the town is mainly in grain, fruit, garden-stuff, wool, and cattle, and is fostered by the fertility of the surrounding country, which is remarkable for the abundance of its streams and water-courses. The great majority of the inhabitants, numbering 23,478 in 1880, are Protestants.

Mühlhausen is one of the oldest towns in Thuringia, and is said to have been fortified in 925. Its early importance is shown by the grant of imperial privileges made to it by the emperor Henry I., and by the diet held there in 1135. At the epoch of the Reformation Mühlhausen became notorious as one of the chief seats of the Anabaptists. Thomas Münzer, one of their leaders, was captured in the vicinity and executed in the town. Internal dissensions and injury received during the Thirty Years' War and the Seven Years' War afterwards reduced Mühlhausen to unimportance. In 1802 it lost its independence and passed to Prussia, in 1807 it was

attached to the kingdom of Westphalia, and in 1815 it again became Prussian. The Teutonic Order established itself at Mühlhausen in 1200, and acquired considerable property there, which ultimately passed into the possession of the town.

MUIR, JOHN (1810-1882), Sanskrit scholar, was born on 5th February 1810 in Glasgow, where his father, William Muir, was a merchant. He was educated at the grammar school of Irvine, the university of Glasgow, and the East India Company's college at Haileybury. He went to India in 1828, and served with distinction in various offices, as assistant secretary to the board of revenue, Allahabad, as magistrate and collector at Azimgarh, as principal of the Victoria College, Benares, and as civil and session judge at Futtehpoor. He was throughout remarkable for his zeal in cultivating and encouraging the study of Sanskrit, in finding methods and furthering schemes for the enlightenment and amelioration of the Hindus. He was persuaded that the only way in which they could escape from the tyranny of caste, with all its attendant evils, was by being made to know how they had become what they were, and also how the freer and more civilized Western peoples believed and lived. He worked assiduously at the organization and development of the higher education of India, and endeavoured to stimulate the learned classes to the study of their own most ancient literature, and of the religious and philosophical literature of the West. He did while in India much work in both departments, and was the occasion of still more being done both by Hindus and Europeans. In 1853 he retired from the service and settled in Edinburgh, where he may be said to have continued under more favourable conditions his Indian labours. In 1862 he endowed the chair of Sanskrit in the university of Edinburgh, and was the main agent in founding the Shaw fellowship in mental philosophy. He was a D.C.L. of Oxford, LL.D. of Edinburgh, and Ph.D. of Bonn. He died 7th March 1882.

In 1858 appeared vol. i. of his *Original Sanskrit Texts* (2d ed. 1868); it was on the origin of caste, an inquiry intended to show that it did not exist in the Vedic age. Vol. ii. (1st ed. 1860, 2d 1871) was concerned with the origin and racial affinities of the Hindus, exhibiting all the then available evidences of their connexion, their linguistic, social, and political kinship, with the other branches of the Indo-European stock. Vol. iii. (1st ed. 1861, 2d 1868) was on the Vedas, a full and exhaustive inquiry as to the ideas of their origin, authority, and inspiration held both by the Vedic and later Indian writers. Vol. iv. (1st ed. 1863, 2d 1873) was a comparison of the Vedic with the later representations of the principal Indian deities, an exhibition of the process by which three gods hardly known to the Vedic hymns became the deities of the former Hindu Trimurti. Vol. v. (1870) was on the Vedic mythology. These texts form still our most exhaustive work on the Vedic age, and show better than any others the point from which the peculiar religious and political development of India started. Dr Muir was also the author of a volume of *Metrical Translations from the Sanskrit*, an anonymous work on *Inspiration*, several works in Sanskrit, and many essays in the *Journal of the Royal Asiatic Society* and elsewhere.

MULA, a town of Spain, in the province of Murcia, is situated 22 miles to the westward of that town on the slope and summit of an eminence on the left bank of the Mula, a small tributary of the Segura, periodically liable to destructive floods. The Sierra Espuña rises on the south to a height of nearly 5200 feet. The usual public buildings, grouped round the central square of the town, present no features of special interest. The ground of the neighbourhood is somewhat broken, but of the cultivable portion about one-half is occupied with olives and vines. The industries and trade of the place are connected principally with agriculture. The population in 1877 was 10,597. About 3½ miles to the eastward are two groups of houses known as the Baños de Mula, with warm sulphurous springs of considerable local repute.

MULBERRY. The mulberry family (*Moraceæ*) is usually included, along with the closely-allied figs, bread-fruits, nettles, hops, planes, and elms, in one vast alliance of monochlamydeous Exogens, the order *Urticaceæ* (or *Ulmaceæ*, as Baillon prefers to call it). The *Moraceæ* include three sub-families, of which the typical genera are: *Dorstenia*, which is almost a Fig; *Broussonetia*, the Paper Mulberry of Japan, the East Indies, and the South Sea Islands; and *Morus*, the Mulberry proper, of which the ten or twelve species are all native to temperate regions in Asia and America, or to hill regions in their tropics, but are readily cultivated in similar climates in Europe, Africa, and Australia.

The Black Mulberry (*Morus nigra*, L.) is mainly cultivated for its purplish black compound fruit (a *sorosis* formed by the aggregated drupes of the whole female inflorescence), which is wholesome and palatable if eaten fresh from the tree before acetous fermentation has had time to set in. Save in syrup, and on account of its rich dark-red colouring matter, it has no longer any pharmaceutical uses. (See HORTICULTURE, vol. xii. p. 272.)

The White Mulberry (*M. alba*, L.), so called from its nearly white fruit, is the one mainly employed in sericulture. There are many varieties, among which the Philippine Mulberry (var. *multicaulis*) is perhaps most highly esteemed. The American and Indian species (*M. americana* and *M. indica*, the latter not to be confounded with *Morinda citrifolia*, a cinchonaceous tree, sometimes also called Indian Mulberry) are also cultivated for the same purpose.

For systematic and descriptive purposes see "Morus" in Baillon, *Hist. d. Plantes*, vi.; or Luerssen, *Med. Pharm. Botanik*, vol. ii. For history and economic uses see F. v. Muller, *Select Plants for Culture in Victoria*, Melbourne, 1876; and Hehn, *Kulturpflanzen*, &c., 3d ed., Berlin, 1877; also SILK.

MULE. Though this term is not unfrequently applied to the produce of two creatures of different species, and is synonymous with hybrid, yet in its ordinary acceptation it is employed to designate the offspring or "cross" between the equine and asinine species. There are two kinds of mule—the *Mule* proper (*Equus Asinus*, var. γ; *Mulus*; Fr., *Mulet* or *Grand Mulet*; Ger., *Grosser Maulesel*), which is the hybrid produce of a male ass with a mare, and the *Hinny* (*Equus Asinus*, var. δ; *Hinnus*; Fr., *Bardot* or *Petit Mulet*; Ger., *Kleiner Maulesel*), the offspring of the stallion and female ass The mule is the more valuable of the two, and to its production the attention of breeders is entirely directed. Indeed, the hinny is so rarely produced, owing to the antipathy of the stallion to the female ass, that many authorities deny its existence.

Intercourse between the mare and male ass is very seldom voluntary; indeed, horses will not associate with asses, and combats between them are often serious. The male ass will freely mate with the mare, but the latter has a strong repugnance to him, as has also the stallion for the female ass. Hence in mule-breeding the mare has to be blindfolded and otherwise deceived, or secured in a travis or by ropes, before she will allow the ass to approach her. Fecundation is not so certain between the ass and horse species as between the male and female of either species, for, while of four mares three at least will be fecundated by the stallion, as a rule only two will be so by the ass.

Fecundation of the hybrid female by the male ass or the stallion is not very rare; but it is otherwise with the male hybrid, no instance being recorded in which he has been prolific, though physically the animal appears to be perfect, and often exhibits an intense ardour for the female. The female mule, when fecundated, seldom reaches the natural term of pregnancy, and rarely brings forth a living offspring. The duration of gestation in a mare impregnated by the ass is a little longer than in impregnation by the stallion,—the average being 375 days. Abortion readily occurs, and more care is necessary than in breeding horses or asses.

In breeding mules the choice in the male parent is limited so far as shape is concerned, as the best-formed asses have, relatively to their height, the head too large, short neck, sides too flat, low shoulders, narrow croup, thin arms and thighs, and very narrow hoofs. To obtain well-shaped mules, therefore, the selection of the mare is of the greatest importance in remedying the defects of the sire. Mares with a small head, round body, short back, wide chest and muscular croup, large thighs and arms, a long neck well set-on, and wide round hoofs are the best. Height is not of so much moment, but a mare measuring from 14 to 15 hands high is preferable. A good height for the male ass is between 13 and 14 hands. Mules inherit to an extraordinary degree the shape and peculiarities of the sire; from the mare they derive size, but rarely her bad shape or unsoundnesses. This is fortunate, for, though it is always desirable to breed from sound well-formed stock, yet mares so unsound or defective in shape as to be disqualified for horse-breeding may be utilized for mule-breeding.

The mule foal is not so strong on its limbs as the horse foal, and it does not grow so quickly. It is longer in reaching maturity, for it is of little use under four years of age; but it is useful for a longer period than the horse, often working until it is twenty, thirty, and even forty years of age. When full grown the mule is from 13 to 15, and sometimes 16 hands high; but those from 14 to 15 hands are generally preferred.

The mule is endowed with the chief characteristics of its parents. In its short thick head, long ears, thin limbs, small narrow hoofs, short mane, absence of chestnuts (horny growths) inside the hocks, and tail destitute of hair at the root it is asinine; while in height and body, shape of neck and croup, uniformity of coat, and in teeth it is equine. It has the voice neither of the ass nor of the horse, however, but emits a feeble hoarse noise. The most common colour of the mule is a brown or bay-brown,—bay, or bright bay, or piebald being rare; a chestnut tint is sometimes noticed. It possesses the sobriety, patience, endurance, and sure-footedness of the ass, and the vigour, strength, and courage of the horse. As a beast of burden it is preferable to the horse, being less impatient under the pressure of heavy weights, while the skin being harder and less sensitive renders it more capable of resisting sun and rain. It is very frugal, easily fed, and equally good for carrying as for drawing loads; it walks well and steadily, easily traverses the worst roads or paths, will climb or descend a steep mountain, or pick its steps by the side of a precipice, with the surety and safety of a goat. For hot and dry countries, especially those which are mountainous, it is well adapted, though cold and wet regions are not suitable for it.

The mule, like the ass, enjoys an extraordinary immunity from disease. After the campaign in Egypt in 1882 the English horses suffered most extensively and severely from a kind of malarious fever, but the mules were entirely exempt. A similar exemption has been noticed during the prevalence of epizootic maladies at other times. Nevertheless those diseases which attack the mule (and the asinine species) run their course with great rapidity; for example, glanders, which often appears in a chronic form in the horse, is most acute in the mule and ass. These are also very liable to tetanus from trifling injuries.

The mule has been in use from very early times; the inhabitants of Mysia and Paphlagonia are said to have been the first breeders. With the Greeks and Romans, the latter especially, the mule was much valued for its good qualities, being employed to draw carriages and carry loads. At the present day it is extensively used in nearly every part of the world, in some countries almost supplanting the horse, while for military purposes it is undoubtedly the best transport animal.

The principal mule countries in Europe are the south of France, Spain, Portugal, and Italy, where they are used for pack and draught. The French mules are most numerous on the borders of the Pyrenees, in Gascony, and in Poitou. In Spain mules are used in the Catalan provinces, in the mountainous districts of Andalusia, and in the province of Alicante. Good draught-mules are bred in La Mancha and in the districts on the slopes of the Pyrenees, where they are employed to carry loads. But in Spain, Italy, and some other countries they are also extensively used in carriages; in Spain particularly, where large, fine mules are bred for this purpose, a pair of these animals will often cost more than a pair of horses. The mules of Asia Minor, Syria, Cyprus, Egypt, and Algeria, as well as those of the district between the Tigris and the Persian frontier and in North China, are good. In the Punjab provinces of British India many excellent mules are bred, breeding being largely promoted by the Government. Good mules are reared in North and South America, the principal districts for breeding them in the United States being Kentucky, Missouri, and Kansas. The Kentucky mules are well shaped and showy, being derived from nearly thoroughbred mares known as Kentucky trotters, while those reared in Missouri are hardy, and can endure much privation and hardship. The Mexican mule, bred by a male ass out of a mustang mare, is also a very hardy, strong, and useful animal.

France is perhaps the most important mule-raising country in Europe, four centres being more particularly devoted to this kind of industry: Poitou, the mountainous districts of central France, the Pyrenees, and Dauphiné. The mules of these different parts chiefly differ in height; those of Poitou are large, powerful, and long in the body, and are mainly exported to the departments of Languedoc and Provence, as well as to Spain, Italy, and America; those of Dauphiné are of medium height, with a short, thick body; while those of the centre and the Pyrenees are lighter and smaller, but more active.

Mule-breeding in Poitou is one of the most important branches of industry, and is supposed to date from the time of Philip V. of Spain, when the particular breeds of horses and asses were imported into that region and Gascony. But there is evidence to show that so early as the 10th century the mules of Poitou were of excellent quality. Though this industry has for a number of years been in a most flourishing condition, this has not always been the case; more than a century ago it was the object of violent attacks, and, had it not been for the great advantages the breeders derived from it and the comparatively small expense incurred in carrying it on, it must have languished or ceased altogether. The Government could not understand why so many mares should be lost to horse production and kept to breed mules alone; and in 1717 the intendant-general of the *haras* went so far as to prohibit male asses being put to mares measuring more than 12 hands from the withers to the top of the hoof under penalty of a fine and confiscation of the ass; and the minister Bertin issued a decree to the effect that all the male asses in Poitou were to be castrated. It was only at a recent period that the *haras* administration ceased to oppose mule-breeding, when it found that it could not be successfully suppressed; for, while in the one department of Deux-Sèvres 13,000 mares were employed in mule production in 1816, fifty years afterwards there were 23,000. Besides, it was discovered not only that this industry added largely to the national wealth but that mules were extremely useful in the army as pack animals, as well as for draught, especially for mountain artillery.

The Poitou mules are large, and strong enough to be used for heavy draught; those produced elsewhere in France, especially in Gascony, are light and better adapted for weight carrying. In Poitou at the present time about 50,000 mares are kept for mule production; of these it is estimated that 38,000 are bred from every year, and of the produce 18,000 are sold annually. In the fairs of Poitou some mules fetch the large price of 1300 to 1500 francs, and many are sold for 900 or 1000 francs. If the average price be fixed at only 600 francs, it will be seen that Poitou alone realizes annually from its mule-breeding no less than 10,800,000 francs. The statistics of 1840 give the number of mules in France at 373,841, of 1852 at 315,331, of 1862 at 330,987, and the census of 1866 at 345,243. The average price of a mule in 1840 was reckoned at 172 francs, in 1852 at 183 francs, and in 1862 at 278 francs. The total value of the mules in 1840 was estimated at 64,284,246 francs, in 1862 it had increased to 92,078,458 francs. The total amount of revenue derived from the trade in mules was: in 1840, 21,244,148 francs; in 1852, 87,548,310 francs; and in 1862, 162,341,162 francs. Since the last-mentioned date it is probable that there has been a further increase.

In the United Kingdom mules are seldom bred, and their services do not appear to be much appreciated; hence their importation is almost *nil*. After the war in Egypt in 1882 a large number of mules which had been purchased by the British Government for that campaign were brought to England and sold by public auction, but the average price realized was probably not more than one-half the amount they had cost in the countries in which they were originally purchased.

Mules have in recent times been largely employed in British campaigns, as in the Crimea, India, Abyssinia, South Africa, and Egypt. In the Abyssinian campaign more than 10,000 pack-mules were obtained from Cyprus, Brindisi, Malta, Smyrna, Gibraltar, Alicante, Valencia, Scanderoon, and Beyrout. The order in which these places are enumerated indicates the relative adaptability of the mules for pack transport during that campaign.

During the Zulu war, South-African or Colonial, South-American, North-American, and French mules were employed; but of these the South-African and South-American were found to be the most suitable.

In India mules form part of the permanent transport of the Punjab irregular force, and are used as pack animals in the mountain batteries. They have also been largely used for transport in the many expeditions which have taken place on the north-western frontier. During the recent Afghan war it was proved that for mountain warfare the mule was by far the best beast of burden; and the director of transport with the Indian division during the late Egyptian campaign reported highly of the work done by the Punjab mules, which are somewhat famed for undergoing a great amount of exertion on little food. The breeding of pack-mules, as also of those adapted for batteries of mountain artillery, too much neglected hitherto, is now much encouraged by the Government of India, which supplies many good male asses to different districts free of charge. These asses are chiefly Arab, Spanish, French, and Italian; but very good animals are at times obtained from Bokhara. By stimulating the breeding of improved asses an increasing supply of good sires and mules is obtained.

The experience of British and other European armies in favour of the mule has been corroborated by that of the United States. In the quartermaster-general's report for 1865 it is stated: "The experience of this (secession) war has convinced all officers of this department that for the army-trains mules are much superior to horses, and of late the horses have almost entirely disappeared from the trains, being transferred to the cavalry or artillery and replaced by mules."

Mules are well adapted for the sick or hospital transport of an army in the field as pack animals, being smaller, surer-footed, and shorter-paced than horses; but they should be specially selected and trained for this purpose, animals of sufficient strength and docility being necessary. A loaded mule will walk a little more than 3 miles an hour, though the pace will much depend upon the roads. The pace is slow moving down hill, quick up hill. Mules sleep from three to four hours in the twenty-four, the soundest sleep being towards dawn. The male mule can carry more weight than the female, though the latter is steadier for work, being more docile; male mules are often vicious and carry loads badly, so that to render them more tractable they are sometimes castrated. For saddle purposes those which more resemble the horse than the ass are preferable.

The carrying power of the mule varies according to a variety of circumstances from 100 lb to 300 lb, the average being about 200 lb including the pack-saddle. In a journey made in 1856 from the city of Del Norte to Chihuahua and Durango in Mexico, a distance of about 500 miles, it was found that out of a train of seventy-five mules the most it was possible for any mule to carry was 275 lb; not more than twenty mules could convey more than 250 lb, the average weight carried by the whole train being a little less than 200 lb. The distance per day was about 15 miles. In another journey it was noted that some of the very best mules, out of a very superior description specially selected, which were loaded with 300 lb, gave out completely at the end of two weeks. In the Abyssinian expedition the load had to be reduced to 100 lb, not including the pack-saddle. It has been stated that a good compact mule, when well trained, properly fitted and handled, will carry in ordinary field service 30 per cent. of its own weight. If the load is in proportion to the size of the animal, small mules have the advantage. A 600 lb mule is quite as good for a 200 lb load as a 900 lb mule is for a 270 lb load.

During the Peninsular War mules were hired by the commissariat for a Spanish dollar a day and rations for the driver. The weight of the load was fixed at 200 lb, and the length of journey in a mountainous country with bad roads was from 10 to 12 miles loaded, 15 to 16 unloaded. The maximum price paid for mules purchased for the Bhutan (India) expedition was 180 rupees; those purchased at Baghdad and Bushire for the Abyssinian expedition averaged 124 rupees 8 annas, in Syria about £20. The mules purchased in the Punjab for the same expedition cost 225 rupees each; those procured in Egypt about £26 10s per animal. The mules purchased in New York for the Zulu war cost £42 per head, though good serviceable mules can be bought at St Louis for from £25 to £30. A firm in London at the same time tendered to supply mules from Spain at £35 each for pack, and £37 10s for draught. The South-African mules bought during the Zulu war cost on an average £23 each.

It has been observed that large mules are not so durable as medium-sized ones, especially for military service. In Algeria it was rare to find a mule over 14 hands more than fifteen years of age, and those approaching 15 hands died younger, while those between 13 and 14 hands were frequently more than twenty years old. The older animals were very often mares. (G. FL.)

MÜLHAUSEN (in French *Mulhouse*), the chief town of a circle and the industrial centre of Upper Alsace, Germany, lies between the Ill, an affluent of the Rhine, and the Rhine-Rhone Canal, about 56 miles to the south of Strasburg and 18 to the north-west of Basel. The old town, surrounded by arms of the Ill, has narrow and irregular streets, while to the south, on the canal, lie the handsome villas and fine promenades of the new town. Most of the older buildings have had to make way for manufactories, so that the town-house, dating from 1552, is an almost solitary witness to the town's mediæval prosperity. The Roman Catholic church of St Stephen, the new Protestant church, the building of the Société Industrielle, and the new Musée are the most prominent modern buildings. The educational institutions include a gymnasium, modern schools, technical schools for the various handicrafts, and an academy in which designers are trained for the textile industries of the town. The most important interest of Mülhausen centres in the making of cotton and muslin goods, and calico-printing. This industry was introduced in 1746, and has since steadily prospered in the hands of several wealthy families which are closely connected by intermarriage and lend each other a firm and powerful financial support. From 20,000 to 24,000 hands in the town and upwards of 60,000 in the neighbourhood are engaged in textile manufactures, the products of which are exported to all parts of the world. The manufactures of machinery, locomotives and railway plant, chemicals, and hardware are also important. A very noteworthy feature connected with the rise of the commercial prosperity of the town is the attention paid by the manufacturers to the wellbeing of their workpeople. In 1853 John Dollfuss, mayor of the town, founded the "workman's quarter" to the north-east of the old town, which now consists of about 1000 model buildings, with public bath-, wash-, and bake-houses,

library, &c. The houses are let on a system by which the occupant becomes the owner after the payment of a certain number of monthly instalments. Besides this more prominent effort, which has been the model for similar attempts in many other towns, a "Société Industrielle" for the encouragement of original discovery and invention among the workmen has existed since 1825, and there are various benevolent societies, including a large institution with 250 beds for the reception of aged workmen. Mülhausen also carries on an active trade in grain, wine, colonial produce, and timber, which is much facilitated by its fine river harbour. After the annexation of Alsace to Germany in 1871 the French sympathies of the inhabitants were shown by the extraordinary decrease in the number of its inhabitants. The population has now, however, regained its full proportions, amounting in 1880 to 63,629, of whom 47,395 were Roman Catholics.

Mentioned as early as 717, Mulhausen was raised to the rank of a free town of the empire in 1198, and received very extensive privileges from Rudolph of Hapsburg in 1273. It suffered considerably in the various wars of the Middle Ages, but generally managed to maintain its independence. In 1446 it expelled its nobles and formed an alliance with Switzerland, and this became a permanent union in 1515. By the peace of Westphalia (1648) it was recognized as an independent ally of the Swiss League. In 1798 it sought incorporation with France from motives of commercial policy, and in 1871 it passed to Germany.

Compare Metzger, *La République de Mulhouse* 717-1798 (1876); and Schall, *Das Arbeiterquartier von Mülhausen* (1876)

MÜLHEIM-AM-RHEIN, the chief town of a circle in the district of Cologne, Prussia, lies on the right bank of the Rhine, 2 miles below Cologne. It is a pretty and well-built town, with important manufactures of silk, velvet, ribbons, sail-cloth, belting for machinery, leather articles, yarn, and chemicals. It also contains a rolling-mill, boiler-works, telegraph-works, malt manufactories, several breweries, and a shipbuilding yard. Mülheim carries on a brisk trade by rail and river, serving as an outlet for the manufactures of Bensberg and Gladbach, and for the wines of the upper Rhine, Nahe, and Moselle. Its educational institutions include a flourishing weaving school and a "real school" of the first class. The most striking building is the modern Gothic church. Though of ancient foundation, Mülheim did not receive a municipal charter till 1587. Its industrial prosperity is in great part due to the influx of Protestants expelled from Cologne at the beginning of the 17th century. The population in 1880 was 20,420.

MÜLHEIM-AN-DER-RUHR, the chief town of a circle in the district of Düsseldorf, Prussia, is situated on the Ruhr, an affluent of the Rhine, about 7 miles from Essen and at the intersection of several railways. Like most of the towns in this district, Mülheim finds its chief industry in iron-working, and contains numerous blast-furnaces, rolling-mills, foundries, and engine-works; it also carries on manufactures of leather, wool, cotton, calico, tobacco, paper, and other miscellaneous goods. About 6,000,000 tons of the Ruhr coal are annually forwarded by river and rail from Mülheim, which also carries on a considerable trade in timber and colonial produce. In the neighbourhood are important sandstone quarries, a large zinc foundry, glass-works, and a carpet manufactory. Mülheim, which possesses a church of the 12th century, was formerly included in the duchy of Berg, and became a town in 1508. In 1880 it contained 22,146 inhabitants, about two-thirds of whom were Protestants.

MULL, an island of Scotland, county of Argyll, and the largest of the Inner Hebrides, is bounded W. by the Atlantic, N. by Loch Sunart, N.E. by the Sound of Mull, and S.E. by the Firth of Lorn. Its area comprises about 235,000 acres, of which only about 13,000 are arable. It is triangular in shape, its greatest length being about 24 miles, and its greatest breadth about 30 miles. Lochs Na-Keal and Scridain form deep indentations on its western coast, and there are a large number of smaller inlets. The coast-line is rocky, and especially on the west there are numerous caverns and horizontal terraces of basalt. The prevailing rock is Old Red Sandstone, but the valleys are filled up with Miocene rocks, consisting chiefly of lava flows and ashes of great terrestrial volcanoes. There is an intrusion of granite towards the south, and also a narrow belt of limestone. The surface is for the most part rugged and mountainous, Ben More rising to the height of 3185 feet. Sheep and black cattle are kept, and barley, oats, and potatoes are grown. Herring fishing is prosecuted at Tobermory, where is one of the best and safest of the western harbours of Scotland. There are several ancient castles, the principal being those of Duart and Aros. The population of the island in 1881 was only 5229.

MÜLLER, JOHANN (1436-1476). See REGIOMONTANUS.

MÜLLER, JOHANN VON (1752-1809), an eminent Swiss historian, was born on 3d January 1752 at Schaffhausen, where his father was a clergyman and rector of the gymnasium. In 1769 he went to the university of Göttingen in order to study theology; but, under the influence of Schlözer, he devoted himself chiefly to historical research. Having passed his theological examination, he was made professor of Greek at the Schaffhausen gymnasium in 1772; and in the same year he published his first work, *Bellum Cimbricum*. By the advice of Bonstetten, his most intimate friend, he went in 1774 to Geneva, where he acted for some time as a tutor in the house of a councillor of state. At Schaffhausen he had begun to study carefully the sources of Swiss history, and at Geneva he continued his investigations with increasing ardour. Lectures on universal history which he delivered during this period formed the basis of his *Vierundzwanzig Bücher allgemeiner Geschichten*, one of his most brilliant writings. In 1780 appeared the first volume of his *Geschichte der Schweizer*, a work which placed him immediately in the front rank of the historical writers of his day. During a visit to Berlin he had an interview with Frederick the Great, from whom he hoped to receive an appointment worthy of his genius and reputation. Disappointed in this expectation, he accepted the professorship of the science of statistics at Cassel, where he wrote his *Reisen der Päpste*. In 1786, having spent two years partly at Bonstetten's country seat and partly in Bern, he entered the service of the elector of Mainz, by whom he was rapidly promoted to important offices in the state. He was also ennobled and made a knight of the empire (Reichsritter). At Mainz he issued several books, besides the second volume of his History of the Swiss Confederation. When Mainz was occupied by the French in 1792 Müller settled in Vienna, where he remained for twelve years, being connected with the imperial library from 1800. Failing to receive the promotion to which he thought he was entitled, and being forbidden after the appearance of the third volume of his Swiss History to continue the publication of the work, he went in 1804 to Berlin, where he became historiographer and a councillor of war. In Berlin he finished the fourth volume of his *Geschichte der Schweizer*, edited the works of Herder, and wrote various treatises for the Academy, including one *Über die Geschichte Friedrich's II.* Up to this time Müller had been an enthusiastic advocate of free institutions, but he now modified his convictions; and in 1807 he accepted from Napoleon the office of secretary of state in the kingdom of Westphalia. Early in 1808 he was transferred at his own request to the office of director-general of public instruction. On 29th May 1809 he died at Cassel.

The value of Müller's contributions to history is marred by the

occasional extravagance and obscurity of his style, and by his inadequate appreciation of the tests of historic credibility; but his learning, his generous sympathies, his grasp of great principles, and his power of vividly presenting some aspects of character secure for his writings an enduring place in German literature. An edition of his *Sämmtliche Werke*, in 40 vols. (published originally in 27 vols. in 1810 to 1819), was issued in 1831 to 1835. Biographies of Müller were compiled by Döring and other writers.

MÜLLER, Johannes (1801-1858), one of the most distinguished physiologists of Germany, was born at Coblentz on 14th July 1801. He became a privat-docent in the university of Bonn in 1824. In 1826 he was appointed extraordinary professor of physiology in the same university, and he became the ordinary professor in 1830. In 1833 he was removed to the university of Berlin, where he filled the chair of anatomy and physiology with great distinction until his death on 28th April 1858. Muller made numerous researches in various departments of physiology, and in particular he extended knowledge as to the mechanism of voice and speech and of hearing, and as to the chemical and physical properties of lymph, chyle, and blood. It was, however, less as an original investigator than as a deep and far-seeing thinker that Müller made his mark on physiological science. From about 1740, when Haller flourished, numerous contributions to physiological science had been made by Whytt, Cullen, John Hunter, Spallanzani, Prochaska, Bichat, Charles Bell, Berzelius, Magendie, and others, but in 1830, when Muller may be said to have begun his labours, it was necessary to reduce these facts to order, to educe general principles, and to direct physiologists into new lines of research indicated by the brilliant discoveries made in physics and in chemistry since the beginning of the century. This Müller did, and he may therefore be regarded as the founder of modern physiology. The appearance of his *Elements of Physiology* between 1837 and 1840 (translated into English by Dr William Baly, and published in London in 1842) was the beginning of a new period. In this work Müller shows remarkable power both in marshalling facts and in philosophical reasoning. As a rule he not merely states and criticizes the labours of others but also contributes the results of his own observations. Whilst he is cautious in the acceptance of theories, he always places them before the reader in an original and suggestive light. The most important portion of the work is that dealing with nervous action and with the mechanism of the senses. Here he states the fruitful principle, not before recognized, that the kind of sensation following irritation of a sensory nerve does not depend on the mode of irritation but upon the nature of the sense-organ. Thus light, pressure, or mechanical irritation acting on the retina and optic nerve invariably produce luminous impressions. This is sometimes termed the law of specific nervous energy. As a teacher Müller exercised a powerful influence, and the great majority of the distinguished physiologists, such as Helmholtz, Du Bois Reymond, Ludwig, Volkmann, and Vierordt, who have made Germany famous in physiological science during the past thirty years, owe much to the germinating ideas of their great teacher.

Besides editing for many years a periodical entitled *Archiv f. Anatomie, Physiologie, u. wissenschaftl. Medicin*, to which he also contributed papers, he published the text-book on physiology above alluded to, and various important memoirs. For a list of these see Poggendorff. *Biog.-Litter. Handwörterbuch*, vol. ii.

Two men of the same name, Johannes Muller, have been celebrated in science: (1) John Müller (1699-1784), a professor of artillery and fortification at Woolwich, who wrote a mathematical treatise published in 1737; (2) Johannes Müller (born 1806), a writer on pharmacy and physiological chemistry, who published many memoirs from 1840 to 1850.

MÜLLER, Karl Otfried (1797-1840), an eminent writer on ancient Greece, was born at Brieg in Silesia on 28th August 1797. His father was a chaplain in the Prussian army. Müller was educated partly in Breslau, partly in Berlin, where his enthusiasm in the study of Greek literature, art, and history was fostered by the influence of Boeckh. In 1817, after the publication of his first work, *Ægineticorum Liber*, he received an appointment at the Magdaleneum in Breslau; and in 1819 he was made a professor of the university of Göttingen, his subject being the archæology of art. His aim was to form a vivid conception of Greek life as a whole; and for this object he carried on a series of profound researches, setting forth the results in his lectures, which produced a great impression on his students, and in numerous works, which marked an epoch in the development of Hellenic studies. Müller's position at Göttingen being rendered unpleasant by the political troubles which followed the accession of Ernest Augustus to the throne of Hanover in 1837, he applied for permission to travel; and in 1839 he left Germany. In April of the following year he reached Greece, having spent the winter in Italy. He carefully investigated the remains of ancient Athens, visited many places of interest in the Peloponnesus, and finally went to Delphi, where he began with his usual zeal to conduct excavations. While engaged in this work he was attacked by intermittent fever, of which he died at Athens on 1st August 1840.

Muller combined with astonishing industry a penetrating critical judgment and an almost unrivalled power of appreciating Greek modes of thought and feeling. Among his historical works the foremost place belongs to his *Geschichte hellenischen Stämme und Staaten*, which includes *Orchomenos und die Minyer* (1820), and *Die Dorier* (1824). He wrote also *Über die Wohnsitze, Abstammung, und ältere Geschichte des macedonischen Volks* (1825); and by his maps he introduced a new standard of accuracy in the treatment of the geography of ancient Greece. In 1828 he published *Die Etrusker*. His *Prolegomenen zu einer wissenschaftlichen Mythologie* (1825) prepared the way for the scientific investigation of myths; and the study of ancient art he promoted by his *Handbuch der Archäologie der Kunst* (1830), and by *Denkmäler der alten Kunst* (1832), which he wrote in association with Österley. In 1840 appeared in England his *History of the Literature of Ancient Greece*, and the original German work from which it had been translated—*Geschichte der griechischen Literatur bis auf das Zeitalter Alexander's*—was issued in Germany by the author's brother in 1841. Amid the labours to which Müller especially devoted himself he found time to write an admirable translation of the *Eumenides* of Æschylus (1833), to prepare new editions of *Varro* (1833) and *Festus* (1839), and to contribute many articles to the *Commentationes societatis regiæ scientiarum Gottingensis*, the *Göttinger gelehrten Anzeigen*, and other periodicals. In 1841 the facts of his life were recorded by Lücke in *Erinnerungen an Otfried Müller*.

MÜLLER, William James (1812-1845), English landscape and figure painter, was born at Bristol on 28th June 1812, and was the son of a Prussian gentleman, a writer on scientific subjects and curator of the Bristol Museum. He received a careful education, being especially trained in botany and natural history, and it was intended that he should become an engineer; but his leanings towards art were too definite to be resisted, and he was placed under J. B. Pyne to receive his first instructions as a painter. His early subjects deal mainly with the scenery of Gloucestershire and Wales, and he learned much from his study of Claude, Ruysdael, and the other earlier landscape-painters. In 1833 he figured for the first time in the Royal Academy with his Destruction of Old London Bridge—Morning, and next year he made a tour through France, Switzerland, and Italy. Four years later he visited Athens, extending his travels to Egypt, and in the sketches executed during this period and the paintings produced from them the power and individuality of the artist are first apparent. Shortly after his return he left Bristol and settled in London, where he exhibited regularly, and found purchasers, at moderate sums, for his pictures. In 1840 he again visited France, where he executed a series of sketches of Renaissance architecture, twenty-five of which were lithographed

and published in 1841, in a folio entitled *The Age of Francis I. of France*. He was anxious again to visit the East, and in 1843 he accompanied, at his own request and his own charges, the Government expedition to Lycia, where he produced an extensive collection of masterly sketches of scenes unfamiliar to the art of his time. They were exhibited in London; their merit was fully recognized by the British public, and the artist received numerous commissions for finished pictures. But his health was seriously impaired, he was suffering from heart-disease and from continued nasal hæmorrhage; and, returning to his native city, he died there on 8th September 1845.

The works of Muller are distinguished by much power and originality, by great speed and directness of execution, by the vigour and emphasis which mark the born sketcher, and by brilliant power of splendid and sharply-contrasting colour. The qualities of tenderness, gradation, and mystery, in which they are commonly wanting, might have been within the reach of the artist had his life been longer. Since his death, and especially since the Gillott sale of 1872, his works have commanded very large prices. The Chess-Players at Cairo, for which Muller received £25, has since sold for upwards of £4000. The print room of the British Museum possesses, through the bequest of Mr John Henderson, a very rich collection of Muller's sketches. His biography by N. Neal Solly was published in 1875.

MULLET. This name is applied to two very different kinds of fishes, which are distinguished as Red Mullets and Grey Mullets. Red Mullets (genus *Mullus*, the name given by the ancient Romans) are marine fishes, with two short dorsal fins remote from each other: the first is composed of feeble spines, the second of branched rays; the anal fin is similar to the second dorsal. The body is covered with large thin scales. The form of the head is quite peculiar and characteristic; its anterior profile slopes downwards to the small mouth, which has but very small and feeble teeth, and from which two cylindrical barbels are suspended. These organs of touch are generally laid backwards and hidden in a groove between the branches of the lower jaw, but can be erected and called into action independently of each other. About forty different species of Red Mullets are known, chiefly from the tropical and sub-tropical parts of the Indo-Pacific Ocean. In the Atlantic the species are much less numerous, the most celebrated being the European *Mullus barbatus* (see vol. xii. p. 638, fig. 10), which is abundant in the Mediterranean, and tolerably common on the coasts of England and Ireland. Formerly a second species, *Mullus surmuletus*, was believed to exist in the European seas, but ichthyologists now incline more and more to the belief that this is only the female of *M. barbatus*.

Red Mullets do not attain to any considerable size, the largest of the tropical species weighing only two or three pounds. They are ground-feeders, evidently using their barbels in discovering their food, which consists of animalcules, worms, and, in the larger species, of small fishes; that they feed on putrid flesh is not borne out by the evidence drawn from their feeble jaws and dentition, but it is very probable that they are attracted to a decomposing body by the presence of the small crustaceans which feast upon it. Although the colours of these fishes are very brilliant, they are simple and evanescent; only a few of the tropical species exhibit ornamentations in the form of black spots or bands. In many, as also in the European species, red colour prevails, and its preservation after death is considered to enhance the fitness of the fish for the table, and consequently its value for the market. To produce the intensity of this red colour, fishermen scale the red mullet immediately before its death, a process by which the red pigment-cells or chromatophores are excited to expand; fishes which are allowed to die in the water show but little red, and therefore red mullets caught by the trawl are less valuable than those obtained in a trammel-net, by which the majority of the fish are secured alive. All the species of Red Mullets seem to be esteemed as food; but none equal in this respect the European species, which was held in exaggerated esteem by the gourmands of the corrupt period of the Roman empire. They exhibited the living fish and allowed them to die at the table immediately before they were consigned to the cook; they kept them in large reservoirs until they were wanted, and paid fabulous prices for fishes somewhat above the average size. In our times red mullets have justly maintained their value as a delicacy for the table; and from a commercial point of view their cultivation in suitable enclosed waters cannot be too strongly recommended to pisciculturists. Unfortunately, very little is known about their habits; during the winter they retire into deep water, late in spring and during the summer they approach the coasts and enter even brackish water, but the state of their sexual organs shows clearly that these fishes do not come towards the shore in order to breed; in fact nothing is known of their propagation.

The Grey Mullets, like the Red Mullets, belong to the spiny-rayed fishes, but form a widely-different and distinct family, *Mugilidæ*. They are not exclusively marine, but freely enter brackish water, live always close to the shore, and some of the tropical forms inhabit the pure fresh water of streams and rivulets, without, however, penetrating far inland. Their body is elegantly formed, wedge-shaped, and covered with scales of moderate size, firmly adherent to the skin. The two short dorsal fins are remote from each other, and the anterior is composed of four stiff spines. The anal fin is similar to the second dorsal; the caudal fin strong and bilobed. The form of the snout is very peculiar and characteristic; the mouth narrow, transverse in the true *Mugil*, and without, or with but feeble, teeth.

About seventy different species are known, from almost every coast of the temperate and tropical zones; they swim in small schools and are abundant wherever they occur. Four species are found on the British coasts—*Mugil septentrionalis*, *Mugil capito*, *Mugil octoradiatus*, and *Mugil auratus*, the first two being about equally and generally distributed, whilst the others are scarcer. Some of the freshwater Grey Mullets of the tropics, especially those of the West Indian and Indo-Pacific islands, have the mouth more lateral or have distinct, though very minute, teeth; they therefore have been formed into separate genera, *Agonostoma* and *Myxus*.

Grey Mullets, at least some of the species, grow to a weight of 10 or 12 lb; but the fish which usually come into the market rarely exceed half that weight. Those in which distinct teeth are developed feed principally on small aquatic animals, whilst the diet of those without teeth consists of animalcules or minute organic substances mixed with the mud or sand which they swallow in large quantities; also confervoid growths to which small shells adhere are freely taken. To prevent the gills from being clogged by sand or mud, a peculiar apparatus separates these organs from the pharynx. Each branchial arch is provided on each side, in its whole length, with a series of closely-set gill-rakers, each series fitting into the series of the adjoining arch; they constitute together a sieve admirably fitted to permit the passage of the water, and to retain at the same time every other substance in the cavity destined for mastication. Also the structure of the intestinal tract is adapted in a remarkable manner to the peculiar diet of these fishes. One portion of the stomach is globular and surrounded by a thick mass of muscles, the cavity being small and coated with a tough epithelium. In fact this structure reminds us of the stomach of birds, in which it also serves for the trituration of hard substances. The intestine itself is long, six or seven times as long as the fish. Grey Mullets are very plainly coloured, generally greenish on the upper parts and more or less silvery on the side. They are wholesome food, well flavoured when taken out of clean water. As young fish bear transport easily, and rapidly grow to a marketable size in suitable enclosed waters, their cultivation deserves every attention on the part of pisciculturists. Indeed, in the fish-farms of Western Italy, grey mullets, besides eels, red mullets, flat-fish, are the principal fish cultivated.

MULLINGAR, a market-town of Ireland, capital of Westmeath, is situated near the Brosna and on the Royal canal, 44 miles west by north of Dublin. The principal buildings are the parish church with tower and spire, the Roman Catholic church, the court-house, the barracks, and the infirmary. Tanning, brewing, and the manufacture of coarse woollens are carried on. The population in 1881 was 4787. Mullingar was one of the ancient palatinate towns. It possessed an Augustine convent founded in 1227, and a

Dominican convent founded in 1239, but both were dissolved by Elizabeth. The town was the headquarters of William III. before the siege of Athlone. It formerly returned two members to parliament, but was disfranchised at the Union.

MULREADY, WILLIAM (1786-1863), subject painter, was born at Ennis, county Clare, on 30th April 1786. When he was about five years old his father, a leather-breeches maker by trade, removed to London, where the son received a tolerable education, chiefly under Catholic priests. He was fond of reading, furtively studying Pope's *Homer* and other works at the book-stalls, and fonder still of drawing.[1] When eleven years old Mulready was employed by an artist named Graham as the model for a figure in his picture of Solomon Blessed by his Father David. The painter's interest in the lad did much to confirm his artistic proclivities; and, having studied at home for two years, Mulready applied for advice to Banks the sculptor, who sent him to a drawing-school and permitted him to work in his own studio. In 1800 he was admitted a student of the Academy, and two years later he gained the silver palette of the Society of Arts. About this time he was associated with John Varley, the eccentric water-colour painter and drawing-master, whom he assisted in the tuition of his band of talented pupils, which included Cox, Fielding, Linnell, William Hunt, and Turner of Oxford. At eighteen he married a sister of Varley's, and at twenty-four he was the father of four sons. The marriage was a singularly unhappy one, and the pair separated before many years. With all these "hostages to fortune" he had a hard struggle, but he was blessed with unfailing energy and the power of steady application. He "tried his hand at everything," as he said, "from a miniature to a panorama." He painted portraits, taught drawing, and up till 1809 designed illustrations to a long series of children's penny books. His first pictures were classical and religious subjects of no great merit, and the early works which he sent to the Academy were mainly landscapes; but he soon discovered his special aptitude for genre-painting, and in 1809 produced the Carpenter's Shop, and in 1811 the Barber's Shop, pictures influenced by the example of Wilkie and the Dutch painters. In 1813 he exhibited his Punch, a work more original and spontaneous in treatment, which brought the artist into notice, and two years later his Idle Boys procured his election as associate. Next year he received full academic honours, and the election was fully justified by the Fight Interrupted which he then exhibited. It was followed by the Wolf and the Lamb (1820), the Convalescent (1822), Interior of an English Cottage (1828), Dogs of Two Minds (1830), the Seven Ages (1838), and in 1839 and 1840 by the Sonnet and First Love, two of the most perfect and poetical of the artist's works. In 1840 he designed the well-known postal envelope for Rowland Hill, and a set of illustrations to the *Vicar of Wakefield*, which were succeeded by his paintings of the Whistonian Controversy (1844), Choosing the Wedding Gown (1846), and Sophia and Burchell Haymaking (1849). His later works, like the Bathers (1849), Mother teaching her Children (1859), and the Toy Seller (1862) show declining powers, mainly attributable to failing health. The last evening of his life was spent at a meeting of the Academy, of which, for nearly fifty years, he had been a most active and efficient member. He died of heart-disease on the 7th July 1863.

In his way of work Mulready was most painstaking and conscientious, executing for each picture very elaborate studies for the several parts, and many sketches for colour and effect. His productions are characterized by accuracy of drawing and richness of colouring; but they want something of the force and fire which come of less considered and elaborate, but more instinctive and inspired, workmanship.

[1] Some reproductions of his early attempts in this direction are given, along with details of his life, in a scarce volume for the young, entitled *The Looking Glass*, written by William Godwin under the *nom-de-plume* of Theophilus Marcliffe, and published in 1805.

MÚLTÁN, or MOOLTAN, a district in the lieutenant-governorship of the Punjab, lying between 29° 22′ and 30° 45′ N. lat. and 71° 4′ and 72° 54′ E. long., is bounded on the N. by the Jhang district, on the E. by that of Montgomery, on the S. by the Sutlej, and on the N.W. by the Chenáb, and has an area of 5880 square miles. Along the banks of the Chenáb, Sutlej, and Rávi extend fringes of cultivation varying in width from 3 to 20 miles, but the interior uplands have the same barren character as the district of MONTGOMERY (*q.v.*). Midway between the boundary rivers, a high dorsal ridge enters from Montgomery, forming a part of the sterile region known as the *bár*. It dips into the lower plateau on either side by abrupt banks, which mark the ancient beds of the Rávi and the Beas (Biás). These two rivers once flowed much farther southward before joining the Chenáb and the Sutlej, and their original course may still be distinctly traced, not only by the signs of former fluvial action, but also by the existence of dried-up canals. At the present day the Beas (Biás) is totally lost to the district, the Rávi merely waters a small corner, and the only rich cultivation is that which stretches along the Chenáb and the Sutlej. The soil, though naturally good, requires abundant irrigation to bring it under efficient tillage. Numerous canals supply water from the Sutlej to the surrounding country, and pools or *jhīls* collect during the rainy weather in the hollows formed by the old watercourses.

The census of 1881 returned the population at 551,964 persons (males 304,517, females 247,447), Mohammedans numbering 435,901, Hindus 112,001, Sikhs 2085, Europeans 1709, Eurasians 110, native Christians 42, and "others" 116. Only one town had a population exceeding 10,000—Múltán, 68,674. Most of the people are grouped together in villages on the irrigated lowlands, only a scattered nomad population being found on the sterile upland tract. In 1878-79 the area under Government assessment was 3,763,200 acres, of which 799,360 were cultivated, 245,760 uncultivable waste, 2,618,080 cultivable, and 100,000 grazing lands. Cultivation is, however, spreading steadily, though the character of the agriculture remains slovenly, as the Ját tribes who comprise the mass of the rural population have not yet lost their predatory and pastoral propensities. Near the city, however, capitalist farmers have brought their land into a high state of cultivation. The areas under crop in 1881-82 were as follows:—rice 15,998, wheat 209,183, great millet 53,605, spiked millet 13,254, Italian millet 724, barley 7460, gram 8303, peas 24,443, and tobacco 1624. Indigo forms the most important commercial staple. The chief articles of trade are sugar and indigo from the lowlands, and wool and *ghi* from the pasture lands of the *bár*. Silk and fine cotton fabrics are produced at Múltán; coarse cotton cloth for home consumption is woven in every village. The Sind, Punjab, and Delhi Railway connects the city with the Northern Punjab and with the East Indian line at Delhi, and the Indus Valley State Railway runs through a portion of the district. The total length of roads is 907 miles and of railways 130.

The total imperial revenue of the district in 1880-81 was 953,408 rupees, of which 561,052 were derived from the land revenue. A small provincial and local revenue is also raised. Education, especially among the Mohammedans, is in a backward state, and in 1872-73 only 3062 children attended school, of whom the Hindus contributed 46 per cent., although they only form 18½ per cent. of the whole population. The climate is proverbial even among the hot and dusty Punjab plains for its heat and dust. The mean temperature in the shade for the six years ending 1876 was in January 54°·70 Fahr., in June 95°·73, in October 76°·68, the average annual rainfall for the same years being 7·27 inches; in 1881 it was only 3·7.

At the time of Alexander's invasion Múltán appears as the chief seat of the Malli; but the Greek power soon came to an end, and the country passed under the rule of the Gupta dynasty of Magadha. The early Arab geographers mention Múltán as forming part of the kingdom of Sind, which was conquered for the caliphate by Mohammed Kásim in the middle of the 8th century. The whole province was conquered by Mahmúd of Ghazni in 1005 A.D. It afterwards formed a part of the Mughal empire of Bábar, and continued so till the extinction of that power. The history of the

district during the latter half of the 18th century is a story of alternate invasion by Marhattás, Afgháns, and Síkhs. At length, in 1779, Muzaffar Khán, of the Sadozai family, succeeded in obtaining the governorship of Múltán. Ranjít Sinh after a long siege carried the capital by storm in 1818, and put Muzaffar Khán and five of his sons to death. In 1829 he made over the administration of Múltán with five neighbouring districts to the famous Sáwan Mall, who raised the province to a state of prosperity by excavating canals and inducing new inhabitants to settle. After the establishment of the council of regency at Lahore, difficulties arose between Múlráj, son and successor of Sáwan Mall, and the British officials, which led to his rebellion, and culminated in the second war and the annexation of the whole of the Punjab. The city of Múltán, after a stubborn defence, was carried by storm in January 1849. The district at once passed under direct British rule, and order has not been disturbed since.

MÚLTÁN, or MOOLTAN, city and headquarters of the above district, is situated 4 miles from the present left bank of the Chenáb (30° 12′ N. lat., 71° 30′ E. long.). The total population in 1881 was 68,674. The town is enclosed on three sides by a wall, but open towards the south, where the dry bed of the old Rávi intervenes between the town and citadel. Large and irregular suburbs have grown up outside the wall since the annexation in 1849. Within the city proper, narrow and tortuous streets, often ending in *culs-de-sac*, fill almost the whole space; but one broad bazaar runs from end to end. The principal buildings include the shrines of two Mohammedan saints and the remains of an ancient Hindu temple. The civil station contains a court-house and treasury, commissioner's offices, jail, post-office, telegraph-office, dispensary, and staging bungalow. The Church Missionary Society maintains a station here. As a trade centre Múltán possesses great importance, its chief imports being cotton and other piece-goods, while the main staples of export are sugar, cotton, indigo, and wool. Trade continues to develop slowly but steadily. The value of the imports for 1879, 1880, 1881 was 75, 84, and 87 lakhs of rupees, and of the exports 36, 37, and 40 lakhs respectively. Lately there has been a great revival of the indigo trade.

MULTIPLEPOINDING is the technical term for a form of action in Scotch law by which conflicting claims to the same fund or property are determined. The action is brought either by the holder or by a claimant in his name. All who have any claims in the fund or property in question are ordered to appear and give in their claims; the court then prefers them according to their respective rights, and the holder of the fund or property in dispute on payment or delivery is absolved from any further claim in regard to it.

MUMMY. The origin of mummification in Egypt has given rise to much learned conjecture (see EMBALMING), now, however, superseded by positive knowledge,—a comparative study of sepulchral texts having furnished Egyptologists with convincing proof that the inviolate preservation of the body was deemed essential to the corporeal resurrection of the "justified" dead. The living man consisted of a body, a soul, an intelligence, and an appearance or *eidolon*,—in Egyptian, a *ka*. Death dissociated these four parts, which must ultimately be reunited for all eternity. Between death on earth and life everlasting there intervened, however, a period varying from 3000 to 10,000 years, during which the intelligence wandered, luminous, through space, while the soul performed a painful probationary pilgrimage through the mysterious under-world. The body, in order that it should await, intact, the return of the soul whose habitation it was, must meanwhile be guarded from corruption and every danger. Hence, and hence only, the extraordinary measures taken to ensure the preservation of the corpse and the inviolability of the sepulchre; hence the huge pyramid, the secret pit, and the subterraneous labyrinth. The shadowy and impalpable *ka*—the mere aspect, be it remembered, of the man—was supposed to dwell in the tomb with the mummied body. This fragile conception was not, however, indestructible, like the soul and the intelligence. Being an aspect, it must perforce be the aspect of something material; and, if the body which it represented were destroyed or damaged, the *ka* was liable to the like mischance. In view of this danger, the Egyptian, by stocking his sepulchre with portrait statues, sought to provide the *ka* with other

Mummies.

chances of continuance, these statues being designed, in a strictly literal sense, to serve as *supports* or dummies for the *ka*. The funereal portrait statues of the ancient empire (Dynasties I. to VI.) are marvels of realistic art in basalt, diorite, limestone, and wood. As many as twenty duplicates have been found in a single tomb, and always secreted in hidden chambers constructed in the thickness of the walls of the sepulchre. The Bulak Museum is very rich in *ka* statues of the ancient empire; and the British Museum contains two in wood from the tomb of Seti I., of the period of Dynasty XIX.

For the processes of mummification, as narrated by Greek and Latin authors, see EMBALMING. The details which follow are taken from original Egyptian sources.

The embalmment of a man of wealth, done in the costliest manner, consisted of—(1) the "going into the good abode," (2) the *Teb*, (3) the *Kesau*. The first of these was the process of evisceration, cleansing, &c., which occupied 15 or 16 days; the second was the salting or bituminizing, and took 19 or 20 days; the third was the spicing and bandaging, and took 34 or 35 days,—making 70 or 72 days in all. There were four special "rituals" for the guidance of the priestly operators and assistants—(1) that of "going into the good abode," which was a kind of surgical manual for the use of the paraschists, enumerating the incisions to be made in the body; (2) that of "the *Kesau*," a corresponding manual for the use of the taricheutes, containing lists of the necessary gums, resins, spices, &c., directions as to the number and nature of the bandages, and prayers to be repeated while adjusting them; (3) the "water ritual" or service-book of litanies, to be recited during the transport of the mummy to the cemetery, which was almost always done by boat; (4) the funereal ritual, performed on consigning the mummy to the tomb. No copy of the first of these documents is known, but its substance is summarized in the Rhind papyrus. Of the other three, contemporary copies written on papyrus exist in various museums. Establishments for the reception and mummification of the dead were attached to all the great cemeteries. These mortuary suburbs, by the Greeks called "memnonia" (μεμνόνεια), were inhabited by a large population of embalmers, mummy-case makers, gilders, painters, scribes, priests, and the like;

and it has been calculated that from 500 to 800 corpses must always have been on hand in the workshops attached to the necropolis of Memphis. To prevent mistakes in delivering the mummies to their families, the bandagers were in the habit of marking the wrappings with the name and age of the deceased, sometimes adding the name and regnal year of the king in whose time he died. The ink in which these entries were written was made from nitrate of silver, like the marking-ink of the present day. The bandages were of linen only. The texture varied with the rank of the mummy, some being as fine as the finest India muslin, and some extremely coarse. The quantity used was enormous, and persons used to save their old linen for this purpose all their lives long. Each limb, finger, and toe was first separately swathed; and finally the whole body was enveloped in numberless convolutions, the contours of the shrunken form being skilfully restored by means of padding. From 700 to 1250 yards of bandages, in strips of 3 to 4 inches wide, have been found on mummies.

The processes of mummification varied in different parts of Egypt and at different periods. The mummies made at Memphis are black, dry, and brittle, whereas those of the best Theban epoch are yellowish, flexible, and so elastic that the flesh yields to the touch of the finger and the limbs may be bent without breaking. Champollion-Figeac attributes this exquisite softness and elasticity to the injection of costly chemical liquids into the veins, whereby the substance of the flesh was preserved. The natron process, on the contrary, destroyed the flesh, leaving only the skin and the bones. By some schools of embalmers the cavity of the skull, after the withdrawal of the brain, was washed out by an injection of refined bitumen, the effect of which was to preserve the membranous covering which has frequently been found inside the brain-pan, dried and unimpaired. Hair is constantly found on the heads of mummies, sometimes plaited, sometimes frizzled,—thus showing that the fashion of wearing wigs was by no means universal. The under bandages of mummies were laid on wet, having probably been dipped in spirits. They sometimes come off with the solidity of a pasteboard mask; and life-like portraits of the dead have been reproduced by simply casting plaster into these masks as into a mould. When Syrian turpentine came into use the Theban mummies ceased to maintain their supremacy, and became even blacker than those of Memphis, the corpse and its bandages forming one solid mass almost as hard as stone. In Memphite mummies, especially of the Ramesside and Saitic periods, the cavity of the chest is found filled with scarabæi and amulets in *pietra dura*. The Theban mummies, on the other hand, from Dynasty XI. to Dynasty XXIII., were adorned with rings, pectoral ornaments, collars, bracelets, &c., in exquisitely-wrought gold inlaid with lapis-lazuli, carnelian, green felspar, and other precious stones. Under the Greeks and Romans the art of mummification declined. Rudely-painted wooden coffins were substituted for the granite sarcophagi and richly-decorated mummy-cases of former times. The mummies became ashen-grey, or, being boiled in bitumen, were black, heavy, and shapeless. Those of Græco-Roman times are frequently found wrapped in painted shrouds, and sometimes with coarsely-daubed encaustic portraits on panel laid above the faces. Dr Birch gives 700 A.D. as the date at which mummification practically ceased. It was formerly supposed that the bodies of the dead were merely desiccated under the ancient empire, and that actual embalming was not practised before 2000 B.C. Recent explorations among the ruined pyramids of Sakkarah have, however, brought to light the mummied corpse of King Merenra, and part of the mummy of King Pepi, his father, both of Dynasty VI. Though denuded of its wrappings by ancient tomb-breakers, the mummy of Merenra is distinctly impressed in the usual manner with marks of its former bandages; and portions of the bandages and a "well-embalmed" hand were recovered from the *dēbris* of that of King Pepi. It is thus shown that mummification was an established rite towards the close of the ancient empire, and that the processes then in use were *identical with those of later times*, which compels us to ascribe a very early date (possibly 3800 or 4000 B.C.) to the beginnings of the art.

The styles of sarcophagi and mummy-cases vary according to periods and places as much as do the styles of mummification. *At Gizeh*, Sakkarah, and Meydûm, in tombs of the ancient empire (Dynasties I. to VI.), the dead are found in unpainted wooden coffins with carved human faces, these coffins being enclosed in massive rectangular sarcophagi of black basalt, red granite, and limestone. Interments of the earliest Theban period (Dynasty XI.) yield cases shaped like the mummy within, and carved out of solid tree-trunks. The masks are painted yellow, white, or black, and on the breast Isis and Nephthys are depicted as if overshadowing the mummy-case with their wings. These cases are sometimes found enclosed in large rectangular wooden coffers with flat lids. With Dynasty XVII. (Theban) there appears the mummy-case with hands carved in relief and crossed upon the breast. The ground-colour of these cases is generally white or black, painted with transverse bands of hieroglyphed inscriptions, the mask is red or gilded, and a vulture with extended wings is depicted on the breast. From Dynasty XIX. to Dynasty XXI. the coffins are highly ornamented in gay colours, figures being more abundant than inscriptions, and yellow varnishes much in favour. The mummy is frequently found enclosed in two, three, and even four such cases, each a size larger than the last. Cases with black grounds are succeeded by cases with brown grounds, and these again by white, resembling those of Dynasties XVII. and XVIII. The masks are now painted red, with richly-decorated head-dresses imitating wigs. Under the priest-king or Amenide domination these triple and quadruple "nests" of mummy-cases are found enclosed in gigantic rectangular outer sarcophagi of wood, highly painted and varnished. From Dynasty XXII. to Dynasty XXVI. the inscriptions are mostly painted in green on a white ground. At Memphis, meanwhile, the granite, basalt, or limestone sarcophagus—sometimes rectangular with rounded corners, sometimes mummy-shaped with sculptured hands and feet, sometimes resembling a long bath—continued to hold its ground. The Saitic period (Dynasties XXVI. to XXX.) is distinguished by the minute finish and artistic beauty of its sculptured sarcophagi in basalt and granite. Last of all, in the extreme decadence of the art, come squared wooden coffins, unpainted, unvarnished, and rudely scrawled in ink with hieroglyphed legends so corrupt as to be almost illegible. According to the religious law of ancient Egypt, the rites of mummification were universal and compulsory, being performed, not only for every native in a style consistent with his rank in life, but also for all strangers and foreigners who died in the land, for all slaves and captives, and even for outcasts, criminals, and lepers.

The most ancient mummified—or, at all events, desiccated—human remains, not being pre-historic, which are known to science are the fragments of the body of Menkara (Gr., Mycerinus), third king of Dynasty IV., and builder of the smallest of the three great pyramids of Gizeh. These fragments were found by Colonel Howard Vyse strewn on the floor of the upper chamber of that pyramid, together with the woollen wrappings and empty

cedar-wood coffin of this pharaoh. All these are now in the British Museum. The fragments consist of the ribs and vertebræ and the bones of the legs and feet, the dried flesh upon the thighs being perfectly preserved. The date of these remains may be approximately assigned to 4000 B.C. Next in antiquity comes the mummy of King Merenra of Dynasty VI., now in the Bulak Museum, the date of which is about 3600 B.C. Most famous and most interesting of all, however, are the royal mummies of Dynasties XVII., XVIII., XIX., and XXI., found at Dair al-Baharí, near the great temple of Queen Hatshepsu, on the left bank of the Nile opposite Karnak, in July 1881. The circumstances of this, the most extraordinary archæological discovery of any age, are too remarkable to be passed over in silence.

The so-called "Theban Arabs" are the busiest treasure-seekers and antiquity-vendors in Egypt. But not often, apparently, have they lighted upon a royal interment. The royal sepulchres in the Valley of the Tombs of the Kings and the neighbourhood have tempted the cupidity of all ages; and we have the direct evidence of two legal documents of the time of Rameses IX., 7th pharaoh of Dynasty XX., to show that bands of organized tomb-breakers infested the cemeteries of Thebes at that comparatively early period.

It is now about twelve years since certain objects of great rarity and antiquity, mostly belonging to the period of the Amenide Dynasty (XXI.), began to find their way to Europe from Upper Egypt. Foremost in importance among the said relics were four funereal papyri (consisting of extracts from the *Ritual* or *Book of the Dead*) written for royal personages of the Amenide family. Concurrent testimony pointed to a family of Arab brothers named Abd er-Rasoul as the original holders of these papyri; it was therefore concluded that the tombs of Pinotem I. and of the Queens Notem-Maut and Hathor Hont-taui (for whom the papyri were written) had by them been discovered and pillaged. The eldest brother was ultimately induced to reveal the secret, and pointed out a lonely spot at the foot of the cliffs not far from the ruins of the great temple of Hatshepsu, on the western bank of the Nile, where the bottom of a hidden shaft opened into a short corridor leading to a gallery 74 metres in length, at the end of which was a sepulchral vault measuring 7 metres by 4. The whole of this gallery and vault were crowded with mummies and mortuary furniture, as sacred vessels, funereal statuettes, canopic and libation vases, and precious objects in alabaster, bronze, glass, acacia wood, and the like. The mummies were thirty-six in number, including upwards of twenty kings and queens from Dynasty XVII. to Dynasty XXI., besides princes, princesses, and high priests, all of which, together with four royal papyri and a miscellaneous treasure consisting of upwards of 6000 objects, are now in the Bulak Museum.

The door-jambs of the mortuary chamber at the end of this long gallery are inscribed with various attestations of burial. These entries refer to interments of members of the Amenide line only. It is also to be observed that only members of that line were found inside the chamber, so proving that the sepulchre was the family vault of the descendants of the first priest-king. All the other royal mummies, and all the objects appertaining to those mummies (that is to say, to the representatives of Dynasties XVII., XVIII., and XIX.) were found in the long gallery outside. When these earlier kings, queens, and princesses were brought out into the light of day, and conveyed to the museum of Bulak, it was discovered that the coffins of some, and the wrappings of others, were inscribed with short official entries written thereon at different times and in different places by successive inspectors of tombs. The dates of these visits of inspection are restricted to the period of Dynasty XXI., whence it is evident that the necessity for protecting the last homes of the illustrious dead was as urgent then as the "Amherst" and "Abbott" papyri prove it to have been in the reign of Rameses IX. The terms of these entries show that it was the duty of the said inspectors to enter the sepulchres of the "royal ancestors," to report upon the condition of the mummies, to repair their wrappings and mummy-cases when requisite, and, if expedient, to remove them from their own tombs into any others which might be regarded as more secure. The mummies and mummy-cases thus inscribed are five in number—namely, those of Amenhotep I., Thothmes II., Rameses I., Seti I., and Rameses II. Two entries on the coffin-lid of Amenhotep I. show his tomb to have been inspected and his wrappings renewed in the 6th year of Pinotem II., fourth of the priest-king line, and again in the 16th year of the pontificate of Masahirti, his son and successor. In the 6th year of Pinotem I. the same was done for the mummy of Thothmes II. The three pharaohs of Dynasty XIX.—Rameses I., Seti I., and Rameses II.—seem, however, to have been still more anxiously looked after. Either because their mummies were specially revered, or because their sepulchres had already been attacked by the tomb-breaking gangs of that period, we find them continually being removed from one tomb to another. In the 6th year of Her-Hor, the founder of the Amenide line, while they yet occupied their own splendid sepulchres in the Valley of the Tombs of the Kings, they were there examined by a Government inspector, who "renewed their funerary equipments" and made an entry of his visit on the coffins of Seti I. and Rameses II. After this Rameses I. and Rameses II. were removed to the tomb of Seti I. (the tomb known as Belzoni's), whence, in the 16th year of Her-Hor, all three mummies, father, son, and grandson, were transferred to the tomb of Queen Ansera. This act of transfer is written, dated, signed, and witnessed on all three coffins. Again, in the 10th year of Pinotem I., grandson of Her-Hor, occur more entries showing them to have been conveyed from the tomb of Queen Ansera to the tomb of one of the Amenhoteps. Finally, in bold hieratic characters, written with marking-ink upon the breast-bandages of Rameses II., we find the following memorandum recording how, ten years later still, the mummy of this illustrious pharaoh was again taken back to the tomb of his father Seti I.:—

"The year 16, the third month of Pert (*i.e.*, seed-time), the sixth day, being the day of carrying the defunct King Ra-user-Ma Sotep-en-Ra, for the renewal of his funerary appointments, into the tomb of the defunct King Ra-men-Ma Seti, by the first prophet of Amen, Pinotem."

At what precise date these and the earlier royal mummies were brought into the Dair al-Baharí vault does not appear; but, as that vault was finally closed on the burial of Queen Isi-em-Kheb, we may conclude that, as a last resource against possible depredation, the "royal ancestors" were deposited therein at or about that time. This would be in the reign of King Menkheperra (brother and successor of Masahirti, and husband of Isi-em-Kheb), whose seal, impressed on clay, was found upon the shattered door of the mortuary chamber. The condition of the various mummies and mummy-cases thus hospitably sheltered gives every indication that their original sepulchres had been previously violated. The coffins of Thothmes III. and Rameses I. are much damaged. That of Rameses II. was probably destroyed, since the one in which his mummy now reposes is of Dynasty XXI. workmanship. The mummy of Rameses I. is doubtful, that of Thothmes I. is missing, as are also the coffins of Queen Ansera, Queen Merit-Amen, and Queen Sitka. The mummy of Thothmes III.—greatest of all Egyptian pharaohs—greater than even Seti I. or Rameses II.—is broken in three pieces. All this is apparently the work of ancient marauders.

For these identifications, see especially two articles on Dynasty XXI. (Manethonian) in the *Zeit. f. Ægyp. Sp.*, 1882, by Dr R. Lepsius and Dr A. Wiedemann; also in *Recueil des Travaux*, vol. iii., 1883, an article on "Relics from the Tomb of the Priest-Kings at Dayr el-Baharee," by Amelia B. Edwards.

MUMPS (syn. *Cynanche parotidæa*, *parotitis*, also "The Branks"), a contagious disease characterized by inflammatory swelling of the parotid and other salivary glands, frequently occurring as an epidemic, and affecting mostly young persons. The disease generally sets in with symptoms of a cold or catarrh accompanied with slight febrile disturbance, but soon the nature of the ailment is announced by the occurrence of swelling and stiffening in the region of the parotid gland in front of the ear. The swelling speedily increases in size and spreads downwards towards the neck and under the jaw, involving the numerous glands in that locality. The effect is to produce much disfigurement, which becomes still greater should the inflammation spread, as often happens, to the glands on the other side of the face and neck. Pain is present in the swollen parts, but it is seldom very severe, nor is there much redness or any tendency to suppuration. There is, however, considerable interference with the acts of mastication and swallowing. After continuing for four or five days the swelling and other symptoms abate, and the parts are soon restored to their normal condition. During the period of convalescence there occasionally occur some swelling and

tenderness in other glands, such as the testicles in males, and the mammæ or ovaries in females, but these are of short duration and of no serious significance. That this complaint is highly contagious is shown by the readiness with which it spreads among children in schools, &c. The nature of the infecting agent is unknown, but the medium of communication is most probably the breath or secretions of the mouth. Mumps is in general a mild disease, and requires but little treatment beyond a gentle laxative, the application of warm fomentations to the swollen and painful parts, and the use of soft food.

MUNCHAUSEN, Baron, the modern Philopseudes, "of whom Ferdinand Mendez Pinto was but a type," is commonly identified with Hieronymus Karl Friedrich von Münchausen, of Bodenswerder in Hanover, who, having entered the Russian service and served in several campaigns against the Turks, amused himself in his retirement by relating extraordinary instances of his prowess as soldier and sportsman. He died in 1797. In 1785 a little book of 48 pages, *Baron Munchausen's Narrative of his Marvellous Travels and Campaigns in Russia*, was published in London. A second edition was printed at Oxford next year; an enlarged London edition speedily followed, and the book had gone through five editions before, in 1787, it was introduced to the German public in a translation, with a preface by the poet Bürger. Bürger very naturally passed in Germany for the writer; and it was not until 1824 that a communication from his editor Karl von Reinhard to the *Gesellschafter* fixed the authorship upon Rudolf Erich Raspe. Raspe, a man of versatile talent, the author of some works on natural history and painting and of a poem entitled *Hermin and Gunilde*, was born at Hanover in 1737, and had been professor of archæology and curator of the museum at Cassel, which appointments he lost upon a charge of stealing medals. He fled to England, where he had already been elected an honorary fellow of the Royal Society, though his name was subsequently expunged. From 1782 to about 1788 he was assay-master and storekeeper at Dolcoath mine in Cornwall, where his ingenuity was still remembered in the middle of the present century. In 1794 he accepted a similar situation at Muckross in Ireland, but died there before entering upon his post. His authorship of Munchausen rests entirely upon the testimony of Von Reinhard, but the fact was in all probability communicated to the latter by Bürger; it has never been disputed, and is confirmed by the appearance of the book in London during Raspe's residence in England. The father of Adolf Ellisen, a recent German editor, visited Baron Munchausen himself in 1795, two years before his death, and found him very uncommunicative. He was convinced, however, by the evidence of acquaintances that the baron had in his younger days fully entitled himself to the distinction thrust upon him by Herr Raspe.

It would be superfluous to descant on the qualities of a work so universally known, whose name has become a household word. It is to be observed, however, that the typical Munchausen is chiefly to be encountered in the 48 pages originally published by Raspe, and that the subsequent accessions, while quadrupling the dimensions of the book, are far from adding proportionably to its merit. There is hardly such another instance in literature of eleven buckram-men growing out of two. The most important of these additions is entitled "A Journey to the Moon and Dog Star," and is mainly borrowed from Lucian's *True History*. A very inferior appendix, published in 1793, represents the baron in conflict with the French revolutionists and Tippoo Saib; and there are several undisguised imitations. The family likeness of the stories published by Raspe himself renders it probable that they were actually derived by him from Münchausen, of whom he speaks respectfully in his preface, attributing to his inventions the moral purpose of "awakening and shaming the common sense of those who have lost it by prejudice or habit." It is nevertheless likely that Münchausen shone rather as a narrator than an inventor, some of his marvels having been traced to Bebel's *Facetiæ*, to Lange's *Mendacia Ridicula*, to Castiglione's *Cortegiano*, and even to a Portuguese magazine.

The best English edition is that by Teignmouth Shore (1872), with illustrations by Gustave Doré and additions by Théophile Gautier; the best German edition that by Ellisen (1849), to which is prefixed a valuable essay upon the literature of pseudology in general. The English edition of 1809 has plates by Rowlandson.

MUNCIE, a city of the United States, county seat of Delaware county, Indiana, 54 miles north-east of Indianapolis. It is a flourishing pleasant-looking place of 5219 inhabitants (census 1880), with city-hall, court-house, public library, and considerable industrial activity.

MUNDAY, Anthony (1553-1633), was one of the most versatile miscellaneous writers of the Shakespearean age. In the introduction to his comedy *John a Green and John a Cumber*, reprinted for the Shakespeare Society, Collier enumerates 47 works of which Munday was whole or part author, the subjects being very various—pastoral poems, journalistic tracts and pamphlets, translations of romances, plays, pageants. The most interesting remnant of this miscellaneous work is a pamphlet reprinted in the Harleian Miscellany, the *English Romayne Life*, a lively account of adventures among Roman Catholic refugees in France and Italy. Munday's experiences were the result of a youthful escapade. Born in 1553, and the son of a London citizen of the Drapers' Company, he had early shown a restless disposition: he took to the stage for some time, tried steady business for a year or two as apprentice to a stationer, tired of it, put all his wealth in his purse, and set out with a companion for the Continent, moved by "a desire to see strange countries as also affection to learn the languages." According to his own account, he was robbed on the way to Amiens, drifted into the company of Popish refugees, and was by them forwarded to Rome, where he obtained admission as a pope's scholar to the English seminary. Returning to England about 1581, and using the knowledge thus gained of designs against the English Government, he was a prominent witness in the trials of Campion and other English Jesuits; and, probably as a reward, was appointed one of the "Messengers of Her Majesty's Chamber." Thereafter he wrote steadily for the booksellers and the theatres, compiling religious publications, putting words to popular airs, translating French romances, and so forth. Webbe in 1586 praised him for his pastorals—only the title is now extant, *Sweet Sobs and Amorous Complaints of Shepherds and Nymphs*;—and in 1598 Meres mentioned him honourably among dramatic writers as "our best plotter." Critical Ben Jonson was less complimentary, and in *The Case is altered* ridiculed Munday severely as "Antonio Balladino, pageant poet." Judging from the plays on the subject of Robin Hood reprinted in Collier's *Supplement to Dodsley's Old Plays*, the joint work of Munday and Chettle, his literary faculty was of a very commonplace description, and deserved Jonson's taunts about "stale stuff" and want of character. Still Munday seems to have been in great request as a collaborator in the last years of Elizabeth's reign, and afterwards he wrote many of the city "pageants." He obtained repute also as an antiquary, and published an enlarged edition of Stow's *Survey of London* in 1618. This last work was the only literary achievement inscribed on his monument in St Stephen's church. He died 10th August 1633.

MUNGO, St. See Kentigern, vol. xiv. p. 40.

MUNGOOS, or MONGOOS. See ICHNEUMON, vol. xii. p. 629.

MUNICH (in German, *München*), the capital of the kingdom of Bavaria and the fourth largest town in the German empire, is situated in an elevated and barren plain to the north of the Bavarian Alps, in 48° 8′ N. lat. and 11° 35′ E. long. Owing to its lofty site (1700 feet above the sea) and the proximity of the Alps the climate is rather changeable, and its mean annual temperature, 49° to 50° Fahr., is little higher than that of many places much farther to the north. The annual rainfall is stated at nearly 30 inches. The situation of Munich is devoid of physical advantages, and the surrounding district is in no way remarkable for its wealth, but the construction of roads and railways has counterbalanced the lack of natural highways, while the central position of the town makes it easy of access from all parts of Europe.

Munich is divided into nineteen municipal districts, fourteen of which, including the old town, lie on the left bank of the small river Isar, while the suburban districts of Au, Haidhausen, Giesing, and Ramersdorf are on the opposite bank. The old town, still containing many narrow and irregular streets, forms a semicircle with its diameter towards the river, while round its periphery has sprung up the greater part of modern Munich, including the handsome Maximilian and Ludwig districts. The wall with which Munich was formerly surrounded has been pulled down, but some of the gates have been left standing. The most interesting of these is the Isar Thor, restored in 1835 and adorned with modern frescos. The Sieges Thor or gate of victory is a modern imitation of the arch of Constantine at Rome, while the stately Propylæa is a reproduction of the gates of the Athenian Acropolis.

At the beginning of the present century Munich was in no way distinguishable from the crowd of second-rate German towns, but since the accession of Louis I. in 1825 it has undergone a metamorphosis of the most remarkable character. This splendour-loving prince devoted himself heart and soul to the embellishment of his "residence," and his successors have followed in his footsteps with such zeal that Munich is now almost unrivalled for architectural magnificence among the smaller capitals of Europe, while its collections of art entitle it to rank alongside of Dresden and Berlin. Most of the modern buildings have been erected after celebrated prototypes of other countries and eras, so that, as has been said by Carrière, a walk through Munich affords a picture of the architecture and art of two thousand years. The want of local colouring is perhaps a blemish in this "museum of architecture," and it has also been objected that the prevailing uniformity of surface in the buildings does not produce sufficient contrast of light and shade. In carrying out his plans Louis I. was ably seconded by the architect Klenze, while the external decorations of painting and sculpture were mainly designed by Cornelius, Kaulbach, and Schwanthaler.

A large proportion of the most notable buildings in Munich are in two streets, the Ludwigstrasse and the Maximilianstrasse, the creations of the monarchs whose names they bear. The former, three-quarters of a mile long and 60 yards wide, chiefly contains buildings in the Renaissance style by Gärtner. The most striking of these are the palaces of Duke Max and Prince Luitpold; the Odeon, a large building for concerts, adorned with frescos and marble busts; the war office; the royal library, in the Florentine Palatial style; the blind asylum; the Ludwigskirche, a successful reproduction of the Italian Romanesque style, containing a huge fresco of the Last Judgment by Cornelius; and, lastly, the university. At one end this street is terminated by the above-mentioned Sieges Thor, while at the other is the Feldherrnhalle or hall of the marshals, a copy of the Loggia dei Lanzi at Florence, containing statues of Tilly and Wrede. Adjacent is the church of the Theatines, an imposing though somewhat over-ornamented example of the Italian Rococo style; it contains the royal burial-vaults. In the Maximilianstrasse, which extends from Haidhausen on the right bank of the Isar to the Max-Joseph Platz, King Maximilian II. tried to introduce an entirely novel style of domestic architecture, formed by the combination of older forms. At the east end it is closed by the Maximilianeum, an extensive and imposing edifice for the instruction of civil servants, adorned externally with large sculptural groups and internally with huge paintings representing the chief scenes in the history of the world. Descending the street towards the west we pass in succession the national museum, the new gymnasium, the provincial government buildings for Upper Bavaria (in which the composite style of Maximilian has been most consistently carried out), and the mint. On the north side of the Max-Joseph Platz lies the royal palace, an extensive building, consisting of the Alte Residenz, the Königsbau, and the Festsaalbau. The old palace, dating from 1601 to 1616, was designed by Peter Candid, and was formerly considered a very fine building. The apartments are handsomely fitted up in the Rococo style, and the private chapel and the treasury contain numerous interesting and valuable objects. The Festsaalbau, erected by Klenze in the Italian Renaissance style, is profusely adorned with mural paintings and sculptures, while the Königsbau, a reduced copy of the Pitti Palace, contains a series of admirable frescos from the *Niebelungenlied* by Schnorr. Adjoining the palace are two theatres, the Residenz or private theatre, and the handsome Hoftheater, the largest theatre in Germany, accommodating 2500 spectators. The Allerheiligen-Hofkirche or court-church is a tasteful little edifice in the Byzantine style with a Romanesque façade, somewhat recalling St Mark's at Venice.

The Ludwigstrasse and the Maximilianstrasse both end at no great distance from the Marien Platz in the centre of the old town. Here stands the Frauenkirche, the cathedral-church of the archbishop of Munich-Freising, with its lofty cupola-capped towers dominating the whole town. Though scarcely a pleasing piece of architecture, it is imposing from its size, and interesting as one of the few examples of indigenous Munich art. On other sides of this square are the old town-house, restored in 1865, and the new town-house, the latter a handsome modern Gothic erection, freely embellished with statues, frescos, and stained-glass windows. The column in the centre of the square was erected to commemorate the defeat of the Protestants near Prague in the Thirty Years' War (1638).

Among the other churches of Munich—the town contains about forty in all—the chief place is perhaps due to St Boniface's, an admirable copy of an early Christian basilica. It is adorned with a cycle of religious paintings by Hess, and the dome is supported by sixty-four monoliths of grey Tyrolese marble. The new parish church of Au, in the Early Gothic style, contains gigantic stained-glass windows and some excellent wood-carving; and the church of St John in Haidhausen is another fine Gothic structure. St Michael's, in the Renaissance style, erected for the Jesuits in 1583 to 1595, contains the monument of Eugène Beauharnais by Thorwaldsen. The façade is divided into stories, and the general effect is by no means ecclesiastical. St Peter's is interesting as the oldest church in Munich (12th century), though no trace of the original basilica remains. One of the two Protestant churches is also a tasteful Gothic building.

The valuable collections of Munich, in virtue of which it ranks among the art-centres of Europe, are enshrined in handsome and appropriate buildings, most of them in

the new Maximilian suburb on the north side of the town. The old Pinakothek, erected by Klenze in 1826-1836 and somewhat resembling the Vatican, is embellished externally with frescos by Cornelius and statues of twenty-four celebrated painters by Schwanthaler. It contains a very valuable and extensive collection of pictures by the earlier masters, the chief treasures being the early German and Flemish works and the unusually numerous examples of Rubens. It also affords accommodation to 300,000 engravings, 10,000 drawings, and a large collection of vases. Opposite stands the new Pinakothek, the frescos on which, designed by Kaulbach, already show the effects of wind and weather. It is devoted to works by painters of the present century, among which Rottmann's Greek landscapes are perhaps the most important. The Glyptothek, a building by Klenze in the Ionic style and adorned with several groups and single statues, contains a valuable series of sculptures, extending from Assyrian and Egyptian monuments down to works by Rauch, Thorwaldsen, and other modern masters. The celebrated Æginetan marbles preserved here, found in the island of Ægina in 1811, are perhaps the most important remains of archaic Greek sculpture. Opposite the Glyptothek stands the exhibition building, in the Corinthian style, used for periodic exhibitions of art. Munich also contains several important private galleries, among which is Count Schack's unequalled collection of modern German pictures. The Kaulbach museum contains a selection of the pictures and sketches left by the painter of that name; and a collection has also been made of the models of Schwanthaler's works.

The scientific collections of Munich are on a par with its galleries of art. The immense collection in the above-mentioned Bavarian national museum, illustrative of the march of progress from the Roman period down to the present day, is superior in completeness and proportion to the similar collections at South Kensington and the Hôtel de Cluny. On the walls is a series of well-executed frescos of scenes from Bavarian history, occupying a space of 16,000 square feet. The ethnographical museum, the museum of plaster casts, the cabinet of coins, and the collections of fossils, minerals, and physical and optical instruments are also worthy of mention. The art union, the oldest and most extensive in Germany, possesses good collections of modern works. The chief place among the scientific institutions is due to the Academy of Science, founded in 1759, to which some of the above-mentioned collections belong. The royal library, containing 1,000,000 printed volumes and numerous valuable manuscripts, occupies the third place among the libraries of the world. The antiquarium is a collection of Egyptian, Greek, and Roman antiquities in the old palace. The observatory is admirably equipped with fine instruments by the celebrated Fraunhofer.

Plan of Munich.

1. Theatinerkirche.
2. Feldherrnhalle.
3. Allerheiligen Church.
4. Residenztheater.
5. Hoftheater.
6. St Michael's Church.
7. Frauenkirche.
8. St Peter's Church.

At the head of the educational institutions of Munich stands the university, founded at Ingolstadt in 1472, removed to Landshut in 1800, and transferred thence to Munich in 1826. It has a staff of about 130 professors and lecturers, and in 1882 was attended by 2183 students. In addition to the four usual faculties there is a fifth, of political economy. In connexion with the university are medical and other schools, a priests' seminary, and a library of 200,000 volumes. The polytechnic institute, contained in a handsome brick edifice, adorned with medallions of celebrated architects, mathematicians, and naturalists, is also attended by a large number of students. Munich contains three gymnasia or grammar-schools, a real-gymnasium, a military academy, a veterinary college, two industrial schools, a commercial school, a school for

architects and builders, several normal schools, a conservatory of music, a dramatic training school, and about twenty-five elementary schools. Among the numerous benevolent institutions the most prominent are the asylums for the blind, the deaf and dumb, and the insane, and the general hospital. The general prison in the suburb of Au is considered a model of its kind; and a large military prison has just been erected. Amongst the other public buildings which call for mention are the crystal palace, 765 feet in length, erected for the great exhibition of 1854; the slaughter-houses, covering 9 acres of ground; the Wittelsbach palace, in the Early English Pointed style; the post-office; the arsenal, containing a military museum; the new railway station, the art-industrial institution, the Maximilian barracks, the corn hall, and the aquarium. Among the numerous monuments with which the squares and streets are adorned, the most important are the colossal statue of Maximilian II. in the Maximilianstrasse, the equestrian statues of Louis I. and the elector Maximilian, and the obelisk erected to the 30,000 Bavarians who perished in Napoleon's expedition to Moscow.

Munich is well supplied with public parks. The English garden, to the north-east of the town, is 600 acres in extent, and was laid out by the celebrated Count Rumford in imitation of an English park. On the opposite bank of the Isar, above and below the Maximilianeum, extend the Gasteig promenades, commanding fine views of the town. To the south-west of the town is the Theresienwiese, a large common where the popular festivals are celebrated. Here is situated the Ruhmeshalle or hall of fame, a Doric colonnade containing busts of eminent Bavarians. In front of it is a colossal bronze statue of Bavaria, 170 feet high, designed by Schwanthaler. An admirable view is obtained from its summit. The finest of the cemeteries of Munich is the southern cemetery, outside the Sendlinger Thor. The dead-houses in the cemeteries are used for the strange custom of keeping the corpses several days before interment, dressed in their usual attire and exposed to public view. The botanical garden, with its large palm-house, and the Hofgarten, surrounded with arcades containing fine frescos of Greek landscapes by Rottmann, complete the list of public parks.

The population of Munich amounted at the census of 1880 to 230,023 inhabitants, of whom 110,033 were males and 119,990 females. These lived in 8791 dwelling-houses, and formed 53,457 households. The garrison numbers about 7000 men. Only 37 per cent. of the inhabitants are born in Munich, most of the remainder coming from the country districts of Bavaria (53 per cent.) and other parts of Germany (5½ per cent.). Another census was taken in 1882 to elicit the occupations of the inhabitants, when it was found that 148,913 persons, or considerably more than half the population (64 per cent.), were supported by trading and manufacturing, while of the remainder 27,592 (12 per cent.) belonged to the official, military, and professional classes, 30,038 (13 per cent.) had no profession, and 24,237 (10·5 per cent.) were engaged in domestic service. The population has been quintupled since 1801, when it was only 48,885. In 1680 it was 20,000, in 1783 it was 38,000. The annual death-rate is high, exceeding 30 per thousand. This is, however, mainly accounted for by the abnormal mortality among children, after allowance for which the rate is not over 20 per thousand. About 85 per cent. of the inhabitants are Roman Catholics, and many of Munich's most characteristic features are due to the fact that it is the centre of Roman Catholicism in southern Germany. Since the census of 1875 the number of Protestants in Munich has increased by 32 per cent., while the Roman Catholics have increased by 13½ per cent. only. Munich is the seat of the archbishop of Munich-Freising, and of the general Protestant consistory for Bavaria. About thirty newspapers are published here, including the principal Ultramontane sheets of south Germany. Some of the festivals of the Roman Church are celebrated with considerable pomp; and the people also cling to various national fêtes, such as the Metzgersprung, the Schäfflertanz (occurring septennially), and the great October festival in the Theresienwiese. The popular life of Munich may be said to revolve round its breweries and beer-gardens, where the manners and customs of the people may be conveniently studied.

The commerce and manufactures of Munich are scarcely commensurate with its artistic importance, though it has lately begun to take rank among the great industrial centres. It has long been celebrated for its artistic handicrafts, such as bronze-founding, glass-staining, silversmith's work, and wood-carving, while the astronomical instruments of Fraunhofer and the mathematical instruments of Ertl are also widely known. Lithography, which was invented at Munich at the end of last century, is still extensively practised here. The other industrial products include wall-paper, railway plant, machinery, gloves, and artificial flowers. Perhaps the most characteristic industry, however, is the preparation of the national beverage. In 1879 upwards of 28 million gallons of beer were brewed in Munich, only one-fifth of which was sent to other parts of Bavaria or exported. This represents an annual consumption of at least 125 gallons per head of population, while the rate in England is only 40 gallons per head. Trade, especially in grain and artistic goods, is now rapidly growing. Four important markets are held at Munich annually.

History.—The history of Munich, as distinct from that of Bavaria, has been very uneventful. The Villa Munichen or *Forum ad Monachos*, so called from the monkish owners of the ground on which it lay, was first called into prominence by Duke Henry the Lion, who established a mint here in 1158, and made it the emporium for the salt of Hallein and Reichenhall. The dukes of the Wittelsbach house occasionally resided at Munich, and in 1255 Louis the Severe made it his capital, having previously surrounded it with walls and a moat. The town was almost entirely destroyed by fire in 1327, after which the emperor Louis the Bavarian, in recognition of the devoted loyalty of the citizens, rebuilt it very much on the scale it retained down to the beginning of the present century. Among the following rulers those who did most for the town in the erection of handsome buildings and the foundation of schools and scientific institutions were Albert V. (1550-1579), William V. (1579-1596), Maximilian I. (1597-1651), Max Joseph (1745-1777), and Charles Theodore (1778-1799). In 1632 Munich was occupied by Gustavus Adolphus, and from 1705 to 1715, and again in 1742, it was in possession of the Austrians. In 1791 the fortifications were razed, and room thus made for the enormous development the city has since experienced. The modern history of Munich may be dated from the accession of King Louis I. in 1825, since which, as already indicated, nearly all the most handsome streets and buildings of the town have been constructed. Like the Bavarians in general, the citizens of Munich are naturally inclined to adhere to the traditionary both in politics and in religion, but of late the population has become permeated with more advanced ideas.

Munich's importance in the history of art is entirely of modern growth, and may be dated from the acquisition of the Æginetan marbles by Louis I., then crown prince, in 1812. Among the eminent artists of this period whose names are more or less identified with Munich were Klenze, Ohlmuller, Gärtner, and Ziebland, the architects; Cornelius, Kaulbach, Schnorr, and Rottmann, the painters; and Schwanthaler, the sculptor. The art of fresco-painting may be said to have been resuscitated in Munich during this reign, and the artistic handicrafts of bronze-founding and glass-staining were also practised with a success previously unknown in modern days. Munich is still the leading school of painting in Germany, but the romanticism of the earlier masters has been abandoned for drawing and colouring of a thoroughly realistic character. Piloty and W. Diez stand at the head of this school.

(J. F. M.)

MUNICIPALITY. A municipality is an organization for the self-government of a city or town by means of a corporation empowered generally to maintain peace and order, and to manage the affairs of the inhabitants. Such a corporation consists of a head as a mayor or provost, and of superior members as aldermen and councillors, together with the simple corporators who are represented by the governing body; it acts as a person by its common seal and has a perpetual succession with power to hold lands subject to the restrictions of the Mortmain Laws, and it can sue or be sued or be indicted, although there are of course many personal matters which do not come within the functions and liabilities of such bodies politic. Where necessary for its primary objects, every corporation has power to make byelaws and to enforce them by penalties, provided they are not unjust or unreasonable or otherwise inconsistent with the objects of the incorporation or charter or other instrument of foundation; and in the case of a municipality such byelaws will be binding even upon strangers within the district.

Great Britain has no general system of self-government. A certain number of cities and towns have been from time to time incorporated by the crown, or have successfully claimed the privilege as existing from time immemorial, either because in fact they have governed themselves from very ancient times, or because they have had such a representation in parliament as led to a presumption of their having been incorporated like the rest. The other urban districts have been regarded as mere "upland towns" or populous townships, with nothing but a parochial organization, or the faint semblance of municipal institutions which grew out of the administration of fairs and markets. These are now comprised in the various local government districts existing under the Public Health Acts, "lighting and watching districts" constituted under an Act passed for the purpose in 1833, and improvement districts governed under the powers given by a number of local Acts. Provision has been made by the Acts which regulate these corporations for the grant of powers of self-government to new municipal boroughs subject to the approval of the committee of the privy council. The making of corporations, however, is regarded as one of the highest prerogatives of the crown, and the legislature has always been careful to avoid unnecessary interference with the right; the functions of the committee are therefore confined to the allowance or refusal of municipal powers as constituted by statute, the right of the crown to make corporations of other kinds being left in theory untouched.

The term "municipal borough" was introduced when the larger corporations were reformed in 1835 to denote a place to which the new powers of self-government were applied, whether such a place were a parliamentary borough or not. It has now become nearly equivalent to "municipality" owing to the provisions of the Act of 1883 for extinguishing the less important of the small unreformed municipalities, and for bringing the rest within the purview of the Municipal Corporations Act, 1882, by which the provisions of the statute of 1835 and its forty-two amending Acts were consolidated. The meaning of the word "borough" has undergone many changes. It seems at first to have denoted a walled town or city, but it was soon applied especially to such of them as possessed some kind of organization for the transaction of the local business. At a later period the term implied the right to be represented in parliament. This may be illustrated by the proceedings in the case of Torrington in the reign of Edward III. This place, whether a "burgh" or a mere "vill," had in fact sent burgesses to parliament, but after it was determined that such representation was improper the town was omitted from the category of boroughs. In summoning the commons to parliament each sheriff was directed to procure the election of two citizens from every city and two burgesses from every borough in his bailiwick. But it soon became the practice to omit places which had been represented, and to include others with no title to the privilege except their situation on the royal demesnes, or their political or commercial importance. It resulted that the word "borough" came to denote only those places which were usually represented in parliament, whether they were walled towns or not, and whether they had or had not received charters of incorporation; and in course of time it was taken for granted that every parliamentary borough must have been incorporated at some ancient time, or in other words was entitled to the privileges of a borough by prescription. The first Reform Act changed the meaning of the word again by depriving the smaller boroughs of their parliamentary functions and reducing them to the same position as those districts which were known as boroughs in a popular sense, as having originally had a representation which had been lost, or as being important places enjoying municipal rights under charters like those which had been granted to the parliamentary boroughs.

We shall now proceed to describe the ordinary constitution of an English municipal borough, omitting the small municipalities which are now in course of extinguishment, and for other reasons omitting the city of London, which, on account of its singular importance and its peculiar circumstances, will probably become without much delay the subject of separate legislation (see LONDON).

These boroughs are governed by corporations composed in each case of a mayor, aldermen, and burgesses, acting by a council elected by the general body of qualified corporators. If the borough is a city, the burgesses are described as the "citizens." With a few exceptions arising under local Acts, the following description applies to all the municipal boroughs in England and Wales, similar provisions having been made for the boroughs of Scotland and Ireland (see vol. iv. p. 63) by Acts of Parliament passed for those parts of the United Kingdom. The powers and duties of the council are defined by the Municipal Corporations Act, 1882, which forms a complete municipal code. The number of councillors varies from twelve to forty-eight according to the size of the borough, and in the case of a new incorporation the number is fixed by a provision in the charter. The qualification of a councillor is to be an enrolled resident burgess, or, if not resident within the district, residing within 15 miles of the borough and having in either case the property qualification required by the Act, provided that he is not a clergyman or a regular dissenting minister, or interested in any office, place, or contract with which the corporation is concerned. The qualification of a burgess is to be enrolled on the burgess-roll as the rate-paying occupier of a house or other building in the borough or within 7 miles distance from it. Women may be burgesses, but are not qualified for corporate office. In many boroughs there are ancient classes of freemen qualified as such by birth, servitude, or marriage (and formerly in many cases qualified by gift or purchase); but these freemen as such have not the rights of burgesses, though they are entitled to the parliamentary franchise and to their share in the charities and corporation property under titles accruing to their class before the reform of 1835. The qualification of an alderman is the same as that of a councillor, and the mayor is chosen from the aldermen, or councillors, or persons qualified for such positions.

The councillors hold office for three years, one-third of their number being annually renewed by ballot. If the borough is divided into wards, an alderman acts as returning-officer for the elections in each ward; if not, the mayor

acts as the returning-officer for the borough. Municipal elections fall within the provisions of the Corrupt Practices Act, 1883. The aldermen hold office for six years, one-half of their number retiring every three years in rotation. The mayor holds office for one year. His election is the first business at the quarterly meeting held on the 9th day of November, when the amount of his remuneration is fixed by the council. He is the only member of the corporation who receives a salary. The council chooses the mayor and aldermen and appoints the officers of the corporation, as the town-clerk and treasurer, the sheriff when the borough is a county of itself, and the coroner and clerk of the peace when it has separate quarter-sessions. The council appoints such general and special committees as may be required, and has the general management of the corporate property, subject to the supervision of the treasury; it makes all necessary byelaws, subject to disallowance by the privy council if necessary. With exceptions arising from the provisions of local Acts, the council regulates the police force, the lighting and watching of the borough, the management of markets and burial-grounds, and the execution of the laws relating to public health. The expenses are defrayed out of the borough fund, which includes the income of the general corporate estate, supplemented by a borough-rate paid out of the poor-rate or assessed upon a similar basis. A watch-rate, if required, may be levied on the whole borough or on a selected portion of the district. When expenditure is required for objects of a permanent character, the council is empowered to raise the amount by loans, charged on the rates and repayable by instalments, subject to the approval of the treasury or other public department entrusted with the control of the matter, according to the nature of the improvement required. The whole of the accounts are audited by borough auditors, of whom one must be a councillor appointed by the mayor, and the other two elected by the burgesses from persons qualified to be councillors. A return is made to the Local Government Board of the receipts and expenditure for the year, and an abstract of all these returns is laid every year before parliament. Some control over the expenditure is also reserved to the High Court of Justice by a provision that all orders for payment must be signed by three councillors and the town-clerk, and that any such order may be moved by *certiorari* into the Queen's Bench Division. The aldermen have no greater powers than other councillors, excepting that they may act as the returning-officers for wards as above mentioned, and that an alderman may act for the mayor if he is temporarily unable to discharge his duty and has not appointed a deputy. The mayor is the head of the corporation, and is *ex officio* a magistrate for the borough and a member of the watch committee. He is the returning-officer at parliamentary elections, and acts with two elected revising assessors as the revising officer if the borough is not represented in parliament. His office is vacated by death or bankruptcy, and must be filled up with all convenient speed after any such vacancy occurs. The last ex-mayor is also *ex officio* a magistrate for the borough.

Where the borough has a separate commission of the peace, the borough justices, with the last-mentioned exceptions, are appointed by the crown. A separate commission does not of itself exempt the borough from the concurrent jurisdiction of the county justices. A stipendiary magistrate may be appointed by a secretary of state on the application of the council, and when appointed he is *ex officio* a justice for the borough. When the borough has a separate court of quarter-sessions the recorder is the judge, but in certain cases may appoint an assistant or deputy; the recorder must be a barrister of five years' standing, and is appointed by the crown on the recommendation of the home secretary; the recorder is also *ex officio* a justice for the borough. When the borough has such a court it ceases to be liable to the county-rate, but must contribute to the expenses arising from prosecution and conviction of prisoners from the borough at the assizes. In the case of boroughs which were liable before 1832 to contribute to the county-rate, a contribution to the expenses of the county is still required. Subject to an exception as to judges and assessors appointed before 1835, and to the provisions of various local Acts, the recorder is the judge of any civil court existing in the borough by prescription.

We shall now discuss more generally the origin of these municipalities upon the Continent as well as in the United Kingdom. The conception of the borough as it now exists has obviously been copied from the Roman *municipium*. As to England, however, the coincidence is in one sense accidental, inasmuch as it had a municipal system before the lawyers adopted the notion of a corporation from the civilians, though it may be true that no such system could grow up without being influenced by ideas which were familiar to the churchmen. In some parts of the West the Roman system appears to have lived on without an actual breach of continuity. The "curia" seems to have continued in the cities of Provence until the outbreak of the great revolution. At Treves and Cologne "the Roman language perished, but the institutions survived;" and the *libertas Romana* or full body of municipal privileges was extended gradually to other cities on the Rhine and the trading communities of Holland and Brabant. It is possible also that some relics of the imperial administration may have continued in southern Italy and in a few of the Lombard cities. One element at least in the corporation of Paris can be traced back to the *Nautæ Parisiaci*, a college of merchants established in the first period of the empire. But the English municipalities are in no sense a legacy from the imperial times, or a continuation of the system which prevailed in the cities of Britain, even in the few instances, as in London, York, and Exeter, where there may have been an unbroken succession of occupancy. Almost all the towns were destroyed in the course of the English conquest, and some which became important again, as Bath, Cambridge, and Chester, are known to have lain waste for centuries. In other instances the English kings soon learned to hold their courts in the fortresses, and to set up their farmsteads in the desolated palaces, or elsewhere a Roman camp may have been taken as a convenient point for a garrison, which in time became a "civil centre" and the site of a municipal borough.

The French municipalities can be traced to several distinct sources of origin. The chief activity was in the north; the southern cities kept their Roman traditions or imitated the Italian model, as those in the east endeavoured to secure the same privileges as the mercantile communities on the Rhine; in the central provinces the towns for the most part retained the organization of the parish, and were rather *bourgeoisies* or privileged market-towns than *communes* with powers of self-government. The rise of the communes began under Philip I., and they became general in the 13th century. The first charter was granted to Le Mans in 1072, and another to Cambray in 1076; these were followed by grants to Laon, Beauvais, Amiens, Soissons, and many other places; and similar privileges were granted in the 12th century by the counts of Flanders, the dukes of Burgundy, and other princes,—the general effect of the grants being to fix the lord's rent or tribute, to commute the military service, and to give jurisdiction to magistrates either freely elected or chosen by the townsmen in conjunction with their feudal lords. Speci-

mens of these charters can be seen in the *Ordonnances des Rois*, Kemble's *Anglo-Saxons*, and Bouthors's *Coutumes locales du Baillage d'Amiens.* They show us a political revolution directed against the feudal lord by townsmen associated in merchant-guilds or sworn into a new sort of brotherhood. To break the oath of loyalty to the commune is a crime of the gravest kind. "If any of us aid or comfort our enemies he is guilty of *lèse-commune*, and we will pull down his house, if we can. . . . Whoever wounds with weapon any of his fellows shall lose his fist or pay nine livres" (Amiens). "The men shall take what wives they please, first asking leave; if their lord refuse, and a man take a wife from another lordship, he shall pay but five sous for a fine. Every one living within the district shall take the communal oath or answer with house or goods" (Soissons). These charters are important because the *communa* of London was founded under Richard I. in direct imitation of the French example, and soon became the type of the independence which the other boroughs continually struggled to attain; and, as in France, the great men deplored the revolt as *tumor plebis, timor regis, tepor sacerdotii*, while the kings for their own purposes encouraged the popular movement. And in the same way Philip Augustus and his successors were so ready to protect the communes that they eventually claimed and obtained an immediate seigniory over all the chartered boroughs to the exclusion of any private lords to whom the towns had formerly belonged. Another point of importance lies in the fact that the lords not only settled the local laws of inheritance and other customs "running with the land," but sometimes changed them at the townsmen's request, as if it were merely an affair between lord and tenant. There are English examples of the same practice, which seems to have been not entirely discontinued until the reign of Edward I. A prerogative of this nature was exercised by the archbishop in Kent, and Simon de Montfort in 1255, at the request of his burgesses of Leicester, abolished the custom of descent to the youngest son. Fitzosberne appears by Domesday Book to have granted a separate set of customs to his "Frenchmen" in Hereford, and a difference of the same kind which existed at Stafford and Nottingham must have been caused by similar grants; in the latter place it was found on a trial in the reign of Edward III. that there were two districts in the town, the one called the "French borough" and the other the "English borough," where descent was to the youngest son, a circumstance which gave its name to the custom of "borough-English."

Municipal freedom was granted in Spain at an earlier date and on an ampler scale, as beseemed the poverty of the kings, the weakness of the nobles, and the constant danger from the Moors. The Visigothic laws were imbued with the principles of the Theodosian code, and it was easy for the Spaniards to regard the incorporated cities as bodies politic of the highest importance. The first instance of the erection of such a community was the grant in 1020 of a code of privileges to Leon. Such grants were treaties between the king and the chartered towns, by which the latter obtained fixed laws, extensive territories, and the choice of their own magistrates in return for a tribute and universal service in the militia. The king appointed a governor to take charge of the fortified places, but in almost every other respect the inhabitants governed themselves. This democratic constitution was after a time impaired by the claims of the knights or "caballeros" to a monopoly of office; but what actually led to its destruction was the increase in the power of the crown. The disorders inseparable from popular elections were declared, as in England under the Tudors, to be a reason for vesting the government in a small and close corporation, which was soon found to be quite amenable to the influence and dictation of the court.

The municipalities of every country have a separate history of their own, and it is difficult to find any general law for determining their methods of development. According to their opportunities the oppressed wear out their conquerors' patience and too often become oppressors in their turn: as the state becomes more complex the old confederacies are broken up, and the scattered communities are reduced to order by a central government, and as privilege begins to disappear the towns are regulated by a common set of rules, or the whole country, as in France, is parcelled out again into a new series of communes or corporate districts. In Spain, as we have seen, the needs of the state gave immediate freedom to its defenders. In Italy the cities grew too soon into a crowd of independent republics. The history of Lincoln and Exeter and the cities of the Danelagh shows that "the tendency of the great cities of England was towards a more than municipal independence" (Freeman, *Engl. Towns*, p. 206). If these movements had not been checked by the Norman Conquest, English history might have been "like that of the imperial kingdoms." But, as this event turned out, there is little in the record of the German cities which bears upon that of English municipalities, excepting some slight resemblances between the powers acquired by the city of London and those of the Hanse towns and the mercantile principalities of Nuremberg and Augsburg. The free cities of Germany were at first divided between the emperors and their immediate vassals, the former ruling through the bishops as imperial vicars; in the 12th century the citizens began to elect councils and to administer a concurrent jurisdiction; in the next century they either purchased full powers or drove out the vicars and bailiffs by force; the revolutions which followed the fall of the Hohenstauffen family enabled the cities to free themselves from the mediate lords and to hold directly of the empire, and they were soon afterwards admitted to the diet on equal terms with the rest of its sovereign constituents.

The borough when it appears in English history is essentially a place of defence, and the definition includes the powerful city which formed the metropolis of an ancient kingdom, the border-fortress, the walled seaport, the "burh" erected in a disaffected province, and the fortified village on the private demesne of the king. There is another sense of the word "borough," as used in Kent and the neighbouring counties, to denote the small rural division which is elsewhere called a "tithing," the constable or tithing-man being the same officer as the "borsholder" or "borough-elder" of the eastern counties; but the verbal similarity is accidental, the rural "borough" having been the district of the "frank-pledges" or neighbours under a pledge or "borh" to act as bail for each other. The borough or "burh" was confined to the precinct of the walls, though the town or city might extend to a greater distance, or the burgesses might be joint-owners of estates outside the lines of defence. There might even be two "burhs" side by side if the nature of the locality required it. We read in the Chronicle, for instance, of the construction of the "northern burh" at Hertford in 913, and of "burhs" being built five years later on both sides of the river at Buckingham; and many other examples will be found collected in Kemble's list of the towns.

Little is known of the civil constitution of the boroughs before the Norman Conquest, and even the Domesday survey fails to give much information as to their internal affairs where the king's rights were not immediately concerned. It appears indeed that Lincoln and the other cities of the Danelagh were almost independent; an aristocratic commonwealth in each case was governed by twelve

hereditary judges, and the same kind of organization, but with a less degree of independence, appeared at Chester and Ipswich. The size and the wealth or power of places like Canterbury, Taunton, and Sandwich entitled them to be treated as separate "hundreds," and the constitution of London must have been based on that of a shire; but, speaking generally, it may be said that the ordinary boroughs were without any powers of self-government. Each borough was administered as if it were a township or cluster of townships, intersected in most cases by a number of separate jurisdictions and subject to the obligations of tenure which bound many of the burgesses to lordships outside the walls. The borough-courts were held by the reeve or bailiff, who may have been in many cases elected, but was always answerable to an external authority. If the place was of mercantile importance it was called a port (from "porta," the city-gate), and the court and its president, as in London, Canterbury, and Bath, were styled the "port-mote" and "port-reeve." In the smaller boroughs the reeve's functions must have resembled those of the steward in the ordinary manorial courts. When municipal rights were granted by the Plantagenet kings this officer was replaced by the "mayor," whose appearance is always the sign of the establishment of an independent commune. The first steps toward self-government were taken when the burgesses became the owners, as at Oxford and Colchester, of property which they managed in common. But a more important source of municipal privilege is to be found in the institution of the guilds, which in time acquired the control and monopoly of the local commerce, so that in the reign of Henry II. the possession of a merchant-guild, or "hanse" as it was called in the north, became "the token of municipal independence," the guild being in fact (if not in theory) the governing body of the town. The courts in later times have accordingly held, as in the case of Totnes, that the grant of *gilda mercatoria* implies the incorporation of the borough. The guilds appear first in a religious form, and date in all probability from the times when the neighbours met to drink at the pagan festivals or the feasts in honour of the dead. Other voluntary associations of the same kind were formed as clubs and friendly societies for mutual insurance and defence. The "frith-gild" of London, as it existed in the reign of Athelstane, and the later "knighten-guild," the "thanes' guild" at Cambridge, and the guilds of Canterbury and Exeter were all fraternities of this kind. The "chapman-guild" ("hanse"- or merchant-guild) was an association on the same model but on a larger scale, comprising all the traders in the town, and assuming the power to make by-laws to regulate all the local business which did not fall within the jurisdiction of the regular courts. The London knighten-guild, until it was suppressed by Henry I., had a legal jurisdiction in the district of Portsoken Ward. The ancient descriptions of Winchester mention two knighten-guilds where the "probi homines" were wont to drink their guild ("potabant gildam suam"). The "gild-halla" of the men of Dover is mentioned in Domesday Book. When the boroughs were enfranchised as communes upon the French model care was taken to confirm and establish these trading fraternities as forming the most important members of the new corporations. Thus in 1200 King John granted to the burgesses of Nottingham "a merchant-guild with all the liberties and free customs which ought to pertain thereto," and the grant to Ipswich in the same reign, besides preserving and extending the jurisdiction of the twelve "portmen" or capital burgesses, provides that the common council shall elect a fit man to be alderman of the merchant-guild. The same king granted to Dublin the right of having guilds "as in Bristol." York and Beverley had the right to have a "hans-hus" some time before, in the latter case by the grant of Archbishop Thurstan in the reign of Henry I.

Another valuable franchise was obtained when the boroughs procured a separate assessment of their dues to the crown. Except in the case of the most important cities, the boroughs were regarded as parts of the counties in which they were situate and as answerable accordingly to the sheriff. It was of the highest importance to the burgesses that their share of the county-dues should be ascertained, and even before the Norman Conquest it became the practice for the borough to answer for its own dues under the name of *firma burgi*. The Domesday survey shows that Dover, Sandwich, Bath, Huntingdon, and many other boroughs had obtained a privilege of this kind. A borough paying its fixed assessment to the king or other lord, through the reeve or alderman of the merchant-guild, was regarded as a single tenant holding the borough for years or at will or in perpetuity, according to the nature of the contract. When its dues and services were assessed in perpetuity the borough was said to be "affirmed" or held in fee-farm, and the burgesses were thenceforth treated as freeholders by a burgage tenure. The only rights remaining to complete their municipal independence were attained when the sheriff's jurisdiction was ousted and the burgesses were allowed to elect their own magistrates to administer justice in the local courts. In the reign of Henry III. the great lords began to enfranchise their boroughs in imitation of the royal example. The statute of *Quo Warranto* in 1290 led to the confirmation of these charters by the crown, and the doctrine was soon established that none but the king had authority to erect a commune. The Scottish boroughs obtained complete self-government at an earlier date, King David I. (1124-1153) having been anxious to attract commerce, and the walled towns having soon been filled with "a crowd of willing settlers from southern Britain and Flanders." Edinburgh, Stirling, Roxburgh, and Berwick formed an important commercial league, "to which the other burghs conformed as they came into existence" (Robertson, *Early Kings*, i. 298). Both in England and Scotland the boroughs, whether founded by the crown or by private lords, were important elements in the state, and in England both classes were summoned to parliament indifferently; in 1298 a writ was issued for Northallerton, which belonged to the bishop of Durham, though by a curious anomaly his city of Durham only acquired the franchise by an Act passed in 1673. The introduction of the metaphysical idea of a corporation may be ascribed to the influence of Bracton, who wrote under Henry III. (*De Legibus*, 57; *Fleta*, vi. 13). We find Edward I. in 1284 granting franchises to the burgesses and community of Nottingham and their "successors," the old form being "to the burgesses and their heirs." The practice varied according as the feudal or the ecclesiastical way of regarding such grants prevailed, until in 1440 the town of Kingston-upon-Hull was incorporated as a body politic according to the modern form. The government of the boroughs soon fell to close governing bodies, constituted by restraining ordinances, and the Stuarts made incessant attempts to obtain the nomination even of these smaller bodies. After the fall of the corporation of London in 1681 the provincial boroughs lost or surrendered their privileges; and, though the charters were revived at the Revolution, the narrow and corrupt system remained. The commissioners of 1835 reported a general and just dissatisfaction with the state of the municipal institutions, great distrust of the self-elected councils, and discontent under the burden of local taxation for purposes which were regarded with suspicion. The reform in England followed swiftly on the famous report, and by Acts passed soon afterwards the Scotch and Irish boroughs,

which had long been subject to the same evils, were reconstructed under similar schemes.

The privileges of the cities in the United States illustrate the proposition that the history of every country must determine the type of its municipalities. In almost all parts of Europe the civic franchises arose out of some treaty or contract between the lord and his dependents; in France, however, the character of the corporations was gradually modified as the communal system was extended to the rural districts. In the United States the French model has been followed with the addition of many improvements; and where self-government has been impartially granted to the county, the township, and the village the purely municipal organization has lost its special significance. It is regarded in the American courts as a revocable agency established by the State (without contract or consideration for the grant) for the purpose of carrying out the necessary details of civil government among the inhabitants of an urban district. It is considered to have no vested right to any of its powers or franchises, which are only allowed to exist in furtherance of the design for which the municipality was constituted, that object being the exercise in subordination to the legislature of certain minor powers of government over part of the territory of the State (see Philadelphia v. Fox, *Supreme Court of Pennsylvania Rep.*, vol. xiv.). Each city has the general powers of a corporation and no others, in the absence of special laws. It has executive functions and powers of legislation for civic purposes, which are vested in the mayor and his subordinate officers, but it is not in any other way entrusted with judicial authority (see *The Political Code of New York*, titles 1, 5, ss. 947-8).

MUNSTER. See Ireland.

MÜNSTER, the chief town of the province of Westphalia in Prussia and formerly the capital of the important bishopric of its own name, lies in a sandy plain about halfway between Cologne and Bremen on the Aa, an insignificant affluent of the Ems. It is one of the best-preserved old towns in Germany, its quaint mediæval character being most strongly impressed on the "prinzipal-markt," with its lofty gabled houses, its arcades, the town-house, a fine Gothic building of the 14th century, and many churches. Of the latter the most important is the cathedral, one of the most original and striking structures in Germany, though much disfigured by modern decoration, rebuilt after a fire in the 13th and 14th centuries, and exhibiting a combination of Romanesque and Gothic forms; the church of St Ludgerus, originally erected in the Romanesque style in 1170, was extended in the Gothic style in 1383, with a tower terminating in a picturesque lantern; the Liebfrauenkirche is of the 14th century; the old church of St Maurice, founded about 1070, was rebuilt in 1859-1862. The room in the town-house in which the peace of Westphalia was signed in 1648 contains portraits of the ambassadors present at the ceremony. On the tower of St Lambert's church (14th century), the upper part of which has recently been pulled down as insecure, were hung three iron cages in which the bodies of John of Leyden and two of his followers were exposed in 1536 (see ANABAPTISTS). The old Stadtkeller contains a collection of early German paintings. The university of Münster, founded after the Seven Years' War and closed at the beginning of this century, is now represented by an academy with the rank of a university, possessing faculties of philosophy and theology (Roman Catholic). In connexion with it are botanical and zoological gardens, several scientific collections, and a library. The private houses of Münster afford an admirable picture of German domestic architecture in the 16th, 17th, and 18th centuries,—Gothic, Renaissance, and Rococo.

Münster is the seat of a Roman Catholic bishop, of the headquarters of an army corps, and of the administrative and judicial authorities of Westphalia. The Westphalian Society of Antiquaries and several other learned bodies also have their headquarters here. The population in 1880 was 40,434, including about 6000 Protestants. The relative industrial importance of Münster is no longer maintained, but manufactures of cotton, linen, and woollens, candles, leather, &c., are still carried on, and it is the centre of a tolerably brisk trade in these products, as well as in cattle, Westphalian hams, grain, and books.

History.—The first historical mention of Münster takes us back to the close of the 8th century, when Charlemagne fixed "Mimegardevoord" as the residence of the newly-appointed bishop of the Saxons. The growth of the settlement round the "Monasterium" was slow, owing to its distance from any navigable river or important highway, and it was not till 1180 that it received a municipal charter. The name Münster had supplanted the original one about a century earlier. During the 13th century Münster was one of the most important members of the Hanseatic League. At the time of the Reformation the citizens were inclined to adopt Protestantism, but the excesses of the ANABAPTISTS (*q.v.*) led to the armed intervention of the bishop and the forcible suppression of all divergence from the ancient faith. The Thirty Years' War, during which Münster suffered most from the Protestant armies, was terminated by the peace of Westphalia or Münster, signed in the town-hall here on 24th October 1648. The authority of the bishops, who seldom resided at Münster, was usually somewhat limited, but in 1661 Bishop Bernhard von Galen took the town by force, built a citadel, and deprived the citizens of most of their privileges. In the Seven Years' War Münster was occupied both by the French and by the allied troops. Towards the close of last century Münster was recognized as one of the intellectual centres of Germany, being the home of Hemsterhuis, Princess Gallitzin, F. von Stolberg, Furstenberg, and other notabilities.

The bishopric of Münster, which possessed the freedom of the empire, embraced an area of 2500 square miles and contained about 350,000 inhabitants. In the 17th century Bishop Galen was of such importance—he supported an army of 20,000 men—that his alliance was sought by the English in 1665 in the war against Holland. The bishopric was secularized and annexed to Prussia in 1803.

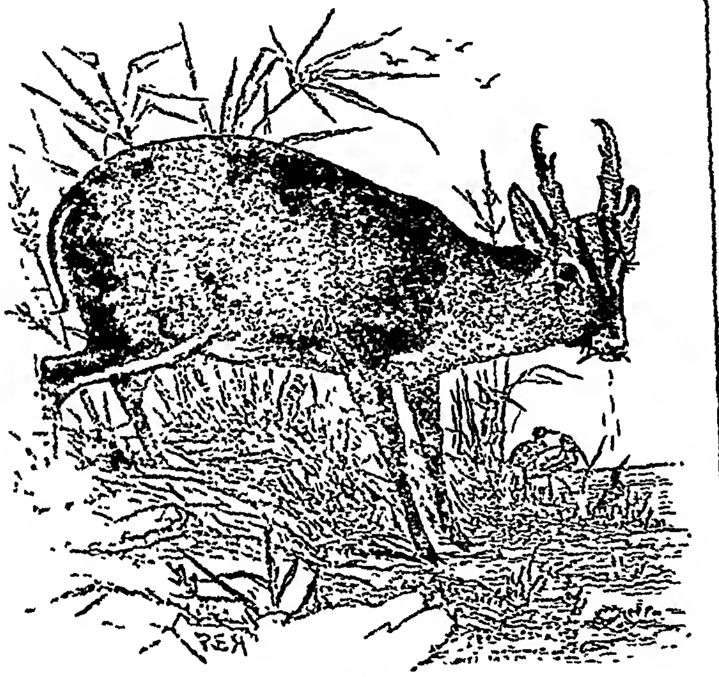
MÜNSTER, SEBASTIAN (1489-1552), Hebraist, geographer, and mathematician, was born at Ingelheim in the Palatinate in 1489. After studying at Heidelberg and Tübingen, he entered the Franciscan order, but abandoned it for Lutheranism about 1529. Shortly afterwards he was appointed court preacher at Heidelberg, where also he lectured in Hebrew and Old Testament exegesis. From 1536 he taught at Basel, where he died of the plague on 23d May 1552. He was described on his tombstone as the Ezra and the Strabo of the Germans.

Munster, a disciple of Elias Levita, was the first German to edit the Hebrew Bible (2 vols. fol., Basel, 1534-1535); this edition was accompanied by a new Latin translation and a large number of annotations. He published more than one Hebrew grammar, and was the first to prepare a *Grammatica Chaldaica* (Basel, 1527). His lexicographical labours included a *Dictionarium Chaldaicum* (1527) and a *Dictionarium Trilingue* (Latin, Greek, and Hebrew, 1530). One of Münster's best-known works was a geography book (*Cosmographia Universalis*, fol., Basel, 1544), which was often reprinted in Latin and frequently translated into German. Among his other writings (for which see the *Biogr. Générale*) are a treatise on dialling (*Horologiographia*, Basel, 1531), one on the planetary motions (*Organum Uranicum*, 1536), and a volume entitled *Rudimenta Mathematica* (Basel, 1551). The notes on the Old Testament are incorporated in the *Critici Sacri*.

MUNTJAK, one of the native names, now generally

adopted in European languages, for a small group of Deer, the members of which are indigenous to the southern and eastern parts of Asia and the adjacent islands, and which are separated by very marked characters from all their allies. They are also called "Kijang" or "Kidjang," and constitute the genus *Cervulus* of Blainville and most zoologists, *Stylocerus* of Hamilton Smith, and *Prox* of Ogilby. They are all of small size compared with the majority of Deer, and have long bodies and rather short limbs and neck. The antlers, which as in most Deer are present in the male only, are small and simple, and the main stem or beam after giving off a very short brow-antler inclines backwards and upwards, is unbranched and pointed, and when fully developed curves inwards and somewhat downwards at the tip. These small antlers are supported upon pedicles or permanent processes of the frontal bones, longer than in any other Deer, and the front edges of which are continued downwards as strong ridges passing along the



Muntjak.

sides of the face above the orbits, and serving to protect the large frontal cutaneous glands which lie on their inner sides. The lacrymal pit of the skull, in which is lodged the large antorbital gland or crumen, is of great depth and extent. The upper canine teeth of the males are strongly developed and sharp, curving downwards, backwards, and outwards, projecting visibly outside the mouth as tusks, and loosely implanted in their sockets. In the females they are very much smaller. The limbs exhibit several structural peculiarities not found in other Deer.

portsmen is "barking
heir alarm-cry, a kind
fox but louder, which may often be heard in the jungles they frequent both by day and by night. When attacked by dogs the males use their sharp canine teeth with great vigour, inflicting upon their opponents deep and even dangerous wounds.

There is some difference of opinion among zoologists as to the number of species of the genus *Cervulus*. Sir Victor Brooke, who investigated this question in 1878 (see *Proceedings of the Zoological Society of London* for that year, p. 898), came to the conclusion that there are certainly three which are quite well marked.

1. *C. muntjac*, found in British India, Burmah, the Malay Peninsula, Sumatra, Java, Hainan, Banca, and Borneo. The general colour is a bright yellowish red, darker in the upper parts of the back; the fore-legs from the shoulder downwards and the lower part of the hind legs, dark bluish brown; anterior parts of the face from the muzzle to between the eyes, brown—a blackish line running up the inside of each frontal pedestal; chin, throat, inside of hind legs, and under surface of tail, white. The female has a black bristly tuft of hair on the spot from which the pedicles of the antlers of the male grow. The average length of the male, according to Jerdon, is 3½ feet, tail 7 inches, height 26 to 28 inches. The female is a little smaller. The specimens from Java, Sumatra, and Borneo are of larger size than those from the mainland, and may possibly be of distinct species or race.

2. *C. lacrymans* of Milne-Edwards, or Sclater's Muntjak of Swinhoe, from Moupin, and near Hangchow, China.

3. *C. reevesi*, a very small species from southern China.

Although the limbs of the modern genus *Cervulus* have attained a considerable degree of specialization, the characters of the cranium, antlers, and teeth are primitive, and almost exactly reproduce those of an extinct deer of the middle Miocene period, the remains of which are found abundantly at Sansan in the south of France and Steinheim in Würtemberg, which has been described under the names of *Dicrocerus elegans* and *Cervus furcatus* (see *Die Fauna von Steinheim*, by Oscar Fraas, Stuttgart, 1870).

MÜNZER, THOMAS (1490-1525), was born of poor parents at Stolberg in the Harz in 1490, was educated at Halle and Leipsic, where he graduated in 1515, was a teacher in the Martini gymnasium in Brunswick in 1517, and was appointed in the beginning of 1520 preacher in the church of St Mary at Zwickau. There he became the opponent of the friars on the one hand and of the humanist reformers on the other, while his eloquence, combined with his Christian socialism, gave him great power over the people. The weavers in Zwickau, who formed the most important trade in the town, were greatly influenced by Nicolas Storch, a man whose views were not unlike those of Münzer, and who had been in close communication with those various communities in Bohemia who represented the Taborites, the Waldenses, and the Bohemian Brethren. Along with Storch, Münzer formed a society governed by twelve apostles and seventy-two disciples, and in secret conventicles proclaimed the revelations of the Holy Spirit which he and some of his disciples claimed to possess. When the society became known conflicts arose with the civil and ecclesiastical authorities, but Münzer and Storch seem to have maintained their position. In September 1521 Münzer and several of his disciples began making preaching tours. Storch went to Wittenberg (see LUTHER), while Münzer went through Bohemia, then by Silesia to Brandenburg and Saxony. He and his followers were fiercely opposed by Luther, who often asked the princes of the lands in which they appeared to banish them from their territories. In 1524 Münzer was in Thuringia and in south Germany. Wherever he went his Christian socialism was welcomed by the oppressed peasantry, who were encouraged to rise in the insurrection (Peasants' War) which ended so disastrously for them at Mühlhausen, 1525. After the battle Münzer was taken prisoner and executed.

Münzer was a successor in the 16th century of those enthusiastic sectaries the mediæval disciples of St Francis of Assisi, who combined intense sympathy with the lot of the poor with strange semi-pantheist notions and ideas of a visible theocracy.

MUNZINGER, WERNER (1832-1875), African traveller and linguist, was born at Olten in Switzerland, 4th April 1832. After studying at Bern, Munich, and Paris, he went to Egypt in 1852 and spent a year in Cairo studying the language. Entering a French mercantile house, he went as leader of a trading expedition to various parts of the Red Sea, fixing his quarters at Massowah in 1854 to 1855, where he acted as French consul. In 1855 he removed to Keren, the chief town of the Bogos, in the north of Abyssinia, which country he explored in all directions during the next six years. In 1861 he joined the expedition under Heuglin to Central Africa, but separated from it in November in northern Abyssinia, proceeding along the Gash and Atbara to Khartūm, and thence in 1862 to Kordofān, failing, however, in his attempt to reach Darfur and Wadai, having meantime succeeded Heuglin as leader of the German African expedition. After a short stay in Europe in 1863, Munzinger returned to the north and north-east borderlands of Abyssinia, and in 1865 was appointed British consul at Massowah, rendering valuable aid to the English Abyssinian expedition in 1867, among other things exploring the almost unknown Afar country. In acknowledgment of his services he received the honour of C.B. In 1868 he was appointed French consul, and in 1871 by the khedive governor of Massowah with the title of "bey." In 1870, with Captain Miles, Munzinger visited the interior of southern Arabia. As governor of Massowah he annexed to Egypt a part of northern Abyssinia, and in 1872 was made pasha and governor-general of the eastern Sudan. In an expedition from Tajurra Bay to the kingdom of Shoa Munzinger was killed, along with his wife and many of his companions, in an attack by a body of Gallas on 14th November 1875, in the neighbourhood of Lake Assal.

Munzinger's contributions to our knowledge of the country, people, and languages of north-eastern Africa are of solid value. See *Proc. R. G. S.*, vol. xiii.; *Jl. R. G. S.*, vols. xxxix., xli., and xlvi. (obituary notice); *Petermann's Mittheilungen* for 1858, 1867, 1872, *et seq.*; Dietschi and Weber, *Werner Munzinger, ein Lebensbild* (1875). Munzinger published the following works:—*Sitten und Recht der Bogos* (1859); *Ostafrikanische Studien* (1864); *Die deutsche Expedition in Ostafrika* (1865); *Vocabulaire de la Langue de Tigré* (1865), besides papers in the geographical serials referred to, and a memoir on the northern borders of Abyssinia in the *Zeitschrift für allgemeine Erdkunde*, new series, iii.

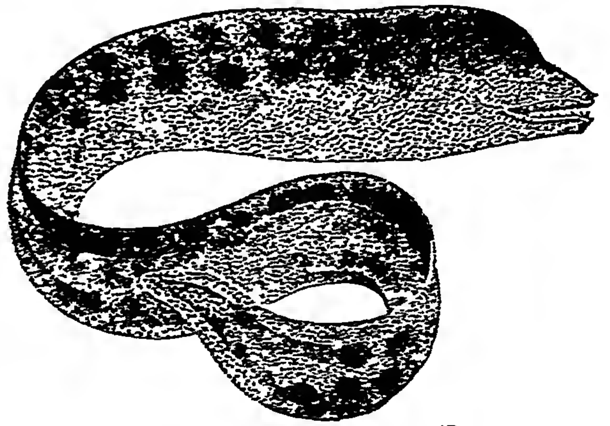
MURĀDĀBĀD, or MORADABAD, a district in the lieutenant-governorship of the North-Western Provinces of India, lying between 28° 13′ and 29° 15′ N. lat. and 78° 7′ and 79° 2′ E. long., is bounded on the N. by Bijnaur and the Tarai, on the E. by Rāmpur state, on the S. by Budāun, and on the W. by the Ganges. The area is 2284 square miles. It lies within the great Gangetic plain, and is demarcated into three subdivisions by the rivers Rāmgangā and Sōt. The eastern tract consists of a submontane country, with an elevation slightly greater than the plain below, and is traversed by numerous streams descending from the Himālayas. The central portion consists of a level central plain descending at each end into the valleys of the Rāmgangā and Sōt. The western section has a gentle slope towards the Ganges, with a rapid dip into the lowlands a few miles from the bank of the great river. The district is well wooded throughout, and mango groves abound in the neighbourhood of the flourishing villages which cluster thickly over its whole surface. Cultivation has spread over almost every part, patches of jungle rarely occurring, and only a few stray pieces of sandy soil or *usar* waste being found among the uplands. Shallow lakes (*jhīls*) are found at intervals, and are in every case utilized for irrigation. The district as a whole consists of a well-tilled and somewhat monotonous alluvial plain, unrelieved by any striking natural features.

The census of 1881 returned the population of the district, exclusive of non-Asiatics, at 1,155,173 (males 610,291, females 544,882), Hindus numbering 767,844, Mohammedans 384,713, and native Christians 1877. Murādābād contains five municipal towns, viz., Murādābād, 67,387; Amroha, 36,145; Sambhal, 35,195; Chandausi, 27,521; Dhanaura, 5294. The total area under cultivation in 1881-82 amounted to 1291 square miles, the staple crops being millets, wheat, pulses, and sugar-cane. As a whole the people are well off and live better than the peasantry in other districts. The labourers too have prospered, wages having risen considerably of late years. About two-sevenths of the cultivators possess hereditary rights, the remainder hold as tenants-at-will. Floods upon the Ganges and Rāmgangā cause much damage to the crops, and the district is liable to famine caused by drought. The last famine in 1868-69 was due to the failure of the rainfall, but with the aid of Government relief the difficulty was tided over without serious losses. The chief exports are grain and sugar-cane. The main line of the Oudh and Rohilkhand railway crosses the district; there are also 654 miles of good road. The total revenue of Murādābād in 1881-82 amounted to 1,775,393 rupees, of which 1,399,450 were derived from the land-tax. Education was carried on in 1881 by means of 181 schools, with an aggregate of 5495 pupils. The climate is generally healthy, except in the submontane tract bordering on the Tarai and in the lowlands of the Ganges and Sōt. The average annual rainfall in the ten years ending 1870 was 37·6 inches. The annual mean temperature is 74°·5 Fahr., the lowest monthly mean being 55° in January, and the highest 88° in June.

For the early history of Murādābād see BAREILLY. It passed into the possession of the British in 1801, and in 1857 joined in the general rebellion of that year. Order was restored early in May 1858.

MURĀDĀBĀD, town and headquarters of the above district, is situated on the right bank of the Rāmgangā river (28° 49′ N. lat., 78° 49′ E. long.), with a population in 1881 of 67,387, of whom 34,584 were males, and 32,803 females. It was founded in 1625 by Rustām Khan, who built the fort which overhangs the river bank. The town forms a large centre of trade in country produce. The engraved metal-ware of Murādābād has lately attracted much attention, the total value of the annual output being about 3½ lakhs of rupees.

MURÆNA is the name of an eel common in the Mediterranean, and highly esteemed by the ancient Romans; it was afterwards applied to the whole genus of fishes to which the Mediterranean species belongs, and which is abundantly represented in tropical and subtropical seas, especially in rocky parts or on coral reefs. Some ninety species are known. In the majority a long



Muræna picta, from the Indo-Pacific.

fin runs from the head along the back, round the tail to the vent, but all are destitute of pectoral and ventral fins. The skin is scaleless and perfectly smooth, in many species ornamented with a pretty pattern of very varied and bright colours, so that these fishes are frequently mistaken for snakes. The mouth is wide, the jaws strong and armed with formidable, generally sharply-pointed, teeth, which enable the Muræna not only to seize its prey (which chiefly consists of other fishes) but also to inflict serious, and even sometimes dangerous, wounds on its enemies. It readily attacks persons who approach its places of concealment in shallow water, and is therefore justly feared by fishermen.

Some of the tropical Murænas exceed a length of 10 feet, but most of the species, among them the Mediterranean species, attain to only half that length. The latter, the "Morena" of the Italians and the *Muræna helena* of ichthyologists, was considered by the ancient Romans to be one of the greatest delicacies, and was kept in large ponds and aquaria. It is not confined to the coasts of southern Europe, but is spread over the Indian Ocean, and is not uncommon on the coasts of Australia. Its body is generally of a rich brown, beautifully marked with large yellowish spots, each of which contains smaller brown spots.

MURAL DECORATION

ate I. THERE is scarcely one of the numerous branches of decorative art which has not at some time or other been applied to the ornamenting of wall-surfaces. It will be convenient to classify the various methods under different heads.[1]

1. *Reliefs sculptured in Marble or Stone.*—This is the oldest method of wall-decoration, of which numerous examples still exist. The tombs and temples of Egypt are very rich in this kind of mural ornament of various dates, extending over the enormous period of nearly 5000 years. These sculptures are, as a rule, carved in very low relief; in many cases they are "counter-sunk," that is, the most projecting parts of the figures do not extend beyond the flat surface of the ground. Some unfinished reliefs discovered in the rock-cut tombs of Thebes show the manner in which the sculptor set to work. The plain surface of the stone was marked out by red lines into a number of squares of equal size. The use of this was probably twofold: first, as a guide in enlarging the design from a small drawing, a method still commonly practised; second, to help the artist to draw his figures with just proportions, following the very strict canons which were laid down by the Egyptians. No excessive realism or individuality of style arising from a careful study of the life-model was permitted.[2] When the surface had been covered with these squares, the artist drew with a brush dipped in red the outlines of his relief, and then cut round them with his chisel.

When the relief was finished, it was, as a rule, entirely painted over with much minuteness and great variety of colours. More rarely the ground was left the natural tint of the stone or marble, and only the figures and hieroglyphs painted. In the case of sculpture in hard basalt or granite the painting appears often to have been omitted altogether. The utter absence of perspective effects and the severe self-restraint of the sculptors in the matter of composition show a keen sense of artistic fitness in this kind of decoration. That the stern rigidity of these sculptured pictures did not in any way arise from want of skill or observation of nature on the part of the artists is at once apparent when we examine their representations of birds and animals; with the most unerring skill and precision the special characteristics of each creature and species were caught by the ancient Egyptian and reproduced in stone or colour, not literally, but in a half-symbolic way, suggesting exactly those peculiarities of form, plumage, or movement which are the essence and "differentia" of each, all other ideas bearing less directly on the point being carefully eliminated.

The subjects of these great mural sculptures are endless in their variety; almost every possible incident in man's life here or beyond the grave is reproduced with the closest attention to detail. The tomb of Tih at Sakkarah (about 4500 B.C.) has some of the finest and earliest specimens of these mural sculptures, especially rich in illustrations of the every-day domestic life and occupations of the Egyptians. The later tombs, as a rule, have sculptures depicting the religious ritual and belief of the people, and the temples combine these hieratic subjects with the history of the reigns and victories of the Egyptian kings.

The above remarks as to style and manner of execution may be applied also to the wall-sculptures from the royal palaces of Nineveh and Babylon, the finest of which are shown by inscriptions to date from the time of Sennacherib to that of Sardanapalus (from 705 to 625 B.C.). These are carved in very low relief with almost gem-like delicacy of detail on enormous slabs of white marble. The sacred subjects, generally representing the king worshipping one of the numerous Assyrian gods, are mostly large, often colossal in scale. The other subjects, illustrating the life and amusements of the king, his prowess in war or hunting, or long processions of prisoners and tribute-bearers coming to do him homage, are generally smaller and in some cases very minute in scale (fig. 1). The arrangement of these

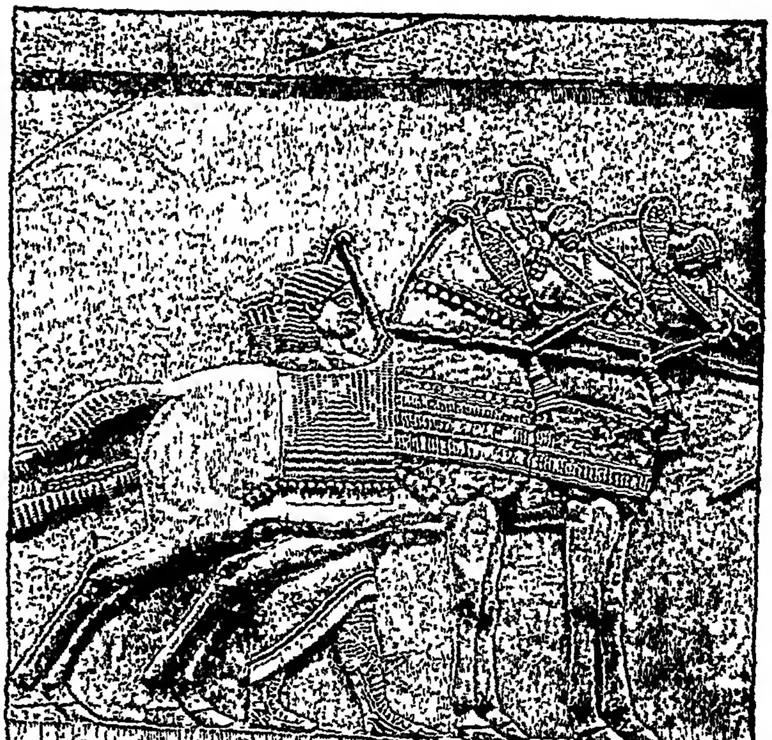


FIG. 1.—Assyrian Relief, on a marble Wall-slab from the Palace of Sardanapalus at Nineveh.

reliefs in long horizontal bands, and their reserved conventional treatment are somewhat similar to those of ancient Egypt, but they show a closer attention to anatomical truth and a greater love for strong dramatic effect than any of the Egyptian reliefs. As in the art of Egypt, birds and animals are treated with far greater realism than human figures. The plastic art of no period or country has ever surpassed in skill and life-like truth the Assyrian reliefs of horses, mules, hounds, goats, lions, and many other animals. A relief in the British Museum, representing a lioness wounded by an arrow in her spine and dragging helplessly her paralysed hind legs, affords an example of wonderful truth and pathos. Very remarkable technical skill is shown in all these sculptures by the way in which the sculptors have obtained the utmost amount of effect with the smallest possible amount of relief (see BABYLONIA, vol. iii. p. 190), in this respect calling strongly

[1] See also FRESCO, MOSAIC, KÁSHÍ, and TAPESTRY.

[2] During the earliest times—more than 4000 years before our era—there appear to have been exceptions to this rule.

to mind a similar peculiarity in the work of the Florentine Donatello.

The palace at Mashita on the hajj road in Moab, built by the Sasanian Chosroes II. (614-627 A.D.), is ornamented on the exterior with very beautiful surface sculpture in stone. The designs of this are of peculiar interest as forming an evident link between Assyrian and Byzantine art, and they are not remotely connected with the decoration on Moslem buildings of comparatively modern date.[1]

Especially in Italy during the Middle Ages a similar treatment of marble in low relief was frequently used for wall-decoration. The most notable example is the beautiful series of reliefs on the west front of Orvieto cathedral, the work of Giovanni Pisano and his pupils in the early part of the 14th century. These are small reliefs, illustrative of the Old and New Testaments, of most graceful design and skilful execution. A growth of branching foliage serves to unite and frame the tiers of subjects.

Of a widely different class, but of considerable importance in the history of mural decoration, are the very beautiful reliefs, sculptured in stone and marble, with which Moslem buildings in many parts of the world are ornamented. These are mostly geometrical patterns of great intricacy and beauty, which cover large surfaces, frequently broken up into panels by bands of more flowing ornament or Arabic inscriptions. The mosques of Cairo, India, and Persia, and the domestic Moslem buildings of Spain are extremely rich in this magnificent method of decoration. In western Europe, especially during the 15th century, stone panelled-work with rich tracery formed a large part of the scheme of decoration in all the more splendid buildings. Akin to this, though without actual relief, is the very sumptuous stone tracery,—inlaid flush into rough flint walls,—which was a mode of ornament largely used for enriching the exteriors of churches in the counties of Norfolk and Suffolk. It is almost peculiar to that district, and is an admirable example of the skill and taste with which the mediæval builders adapted their method of ornamentation to the materials which came naturally to hand.[2]

2. *Marble Veneer.*—Another widely-used method of mural decoration has been the application of thin marble linings to wall-surfaces, the decorative effect being produced by the natural beauty of the marble itself and not by sculptured reliefs. One of the oldest buildings in the world, the so-called "Temple of the Sphinx" among the Gizeh pyramids, is built of great blocks of granite, the inside of the rooms being lined with slabs of beautiful semi-transparent African alabaster about 3 inches thick. In the 1st century very thin veneers of richly-coloured marbles were largely used by the Romans to decorate brick and stone walls. Pliny (*H. N.*, xxxvi. 6) speaks of this practice as being a new and degenerate invention in his time. Many examples exist at Pompeii and in other Roman buildings. Numerous Byzantine churches, such as St Saviour's at Constantinople, and St George's, Thessalonica, have the lower part of the internal walls richly ornamented in this way. It was commonly used to form a dado, the upper part of the building being covered with mosaic. The cathedral of Monreale and other Siculo-Norman buildings owe a great deal of their splendour to these linings of richly-variegated marbles. In most cases the main surface is of light-coloured marble or alabaster, inlaid bands of darker tint or coloured mosaic being used to divide the surface into panels. The peculiar Italian-Gothic of northern and central Italy during the 14th and 15th centuries, and at Venice some centuries earlier, relied greatly for its effects on this treatment of marble. St Mark's at Venice and the cathedral of Florence are magnificent examples of this work used externally. It is in every case a mere skin, and is in no way connected with the stability of the structure. Both inside and out most of the richest examples of Moslem architecture owe much to this method of decoration; the mosques and palaces of India and Persia are in many cases completely lined with the most lustrous and brilliant sorts of marble, of contrasting tints arranged and fitted together with consummate skill and knowledge of harmony.

3. *Wall-Linings of Glazed Bricks or Tiles.*—This is a very important class of decoration, and from its almost imperishable nature, its richness of colour, and its brilliance of surface is capable of producing a splendour of effect that can only be rivalled by glass mosaics. In the less important form—that of bricks modelled or stamped in relief with figures and inscriptions, and then coated with a brilliant colour in siliceous enamel—it was largely used by the ancient Egyptians and Assyrians as well as by the later Sasanians of Persia. In the 11th and 12th centuries the Moslems of Persia brought this art to great perfection, and used it on a large scale, chiefly, though not invariably, for internal walls. The main surfaces were covered by thick earthenware tiles, overlaid with a white enamel. These were not rectangular, but of various shapes, mostly some form of a star, arranged so as to fit closely together. Very delicate and minute patterns were then painted on the tiles, after the first firing, in a copper-like colour with strong metallic lustre, produced by the deoxidization of a metallic salt in the process of the second firing. Bands and friezes with Arabic inscriptions, modelled boldly in high relief, were used to break up the monotony of the surface. In these, as a rule, the projecting letters were painted blue, and the flat ground enriched with very minute patterns in the lustre-colour. This combination of bold relief and delicate painting produces great vigour and richness of effect, equally telling whether viewed in the mass or closely examined tile by tile. In the 15th century lustre-colours, though still largely employed for plates, vases, and other vessels, especially in Spain, were but little used for tiles; and another class of ware, rich in the variety and brilliance of its colours, was extensively used by Moslem builders all over the Mohammedan world. The most sumptuous sorts of tiles used for wall coverings are those of the so-called "Rhodian" and Damascus wares, the work of Persian potters at many places. Those made at Rhodes are coarsely executed in comparison with the produce of the older potteries at Ispahan and Damascus (see POTTERY). These are rectangular tiles of earthenware, covered with a white "slip" and painted in the most brilliant colours with slightly conventionalized representations of various flowers, especially the rose, the hyacinth, and the carnation. The red used is a very rich harmonious colour, applied in considerable body, so as to stand out in slight relief. Another class of design is more geometrical, forming regular repeats; but the most beautiful compositions are those in which the natural growth of trees and flowers is imitated, the branches and blossoms spreading freely over a large surface covered by hundreds of tiles

[1] Among the Mashita carvings occurs that oldest and most widely spread of all forms of Aryan ornament—the sacred tree between two animals. The sculptured slab over the "lion-gate" at Mycenæ has the other common variety of this motive—the fire-altar between the beasts. These designs, occasionally varied by figures of human worshippers instead of the beasts, survived in a most extraordinary way long after their meaning had been forgotten; even down to the present day in some form or other they frequently appear on carpets and other textiles of Oriental manufacture.

(1840-52); Gruner, *Die Bas-reliefs . . . zu Orvieto* (1858); Champollion, *Mon de l'Égypte* (1835-45); Mariette, *Descr. de Denderah* (1873-75); Rossellino, *Monumenti d'Egitto*, 1826.

without any repetition. One of the finest examples is the "Mecca wall" in the mosque of Ibráhím Agha, Cairo; and other Egyptian mosques are adorned in the same magnificent way (fig. 2). Another variety, the special production

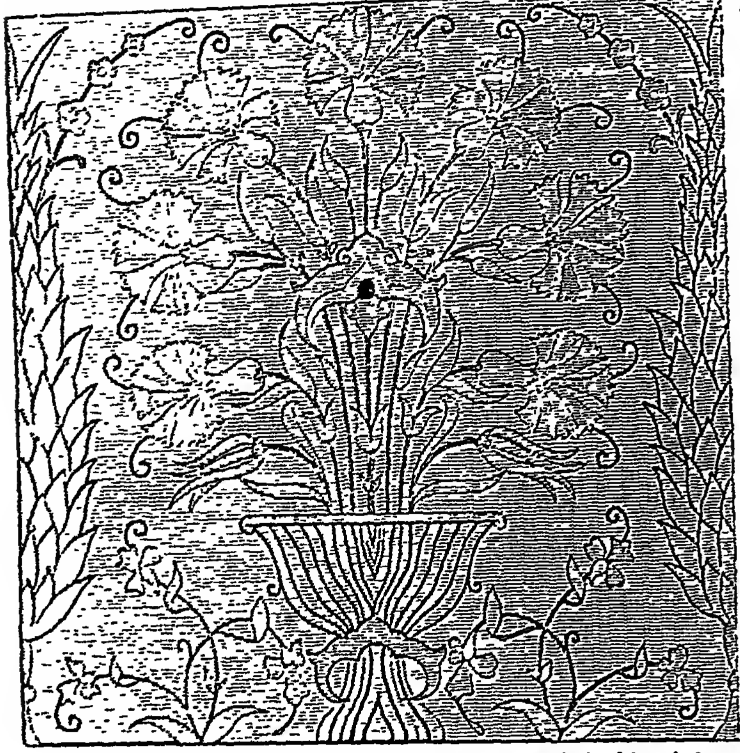

Fig. 2.—One of the Wall-Tiles from the Mosque of Ibrahim Agha, Cairo. 10 inches square.

of Damascus, has the design almost entirely executed in blue. It was about the year 1600 A.D., in the reign of Shah Abbas I., that this class of pottery was brought to greatest perfection, and it is in Persia that the most magnificent examples of its use are to be found. Nothing can surpass the splendour of effect produced by these tile-coverings, varieties of which, dating from the 12th to the 17th centuries, were largely used in all the chief buildings of Persia. The most remarkable examples for beauty of design and extent of surface covered by these tiles are the mosque at Tabríz, built by Ali Khoja in the 12th century, the ruined tomb of Sultan Khodabend (1303-1316 A.D.) at Sultanieh, the palace of Shah Abbas I. and the tomb of Abbas II. (*ob.* 1666 A.D.) at Ispahan, all of which buildings are covered almost entirely inside and out with this magnificent sort of decoration.

Another important class of wall-tiles are those manufactured by the Spanish Moors, called "azulejos," especially during the 14th century. These are in a very different style, being designed to suggest or imitate mosaic. They have intricate interlacing geometrical patterns marked out by lines in slight relief; brilliant enamel colours were then burned into the tile, the projecting lines forming boundaries for the pigments. A very rich effect is produced by this combination of relief and colour. They are mainly used for dados about 4 feet high, often surmounted by a band of tiles with painted inscriptions. The Alhambra and Generalife palaces at Granada, begun in the 13th century, but mainly built and decorated by Yúsuf I. and Mohammed V. (1333-1391 A.D.), and the Alcazar at Seville [illegible] utiful examples of these "azulejos." [illegible] chiefly owes its decorations to Pedro [illegible] D.), who employed Moorish workmen [illegible] and other ornaments. Many other [illegible] n Spain are enriched in the same way, [illegible] 16th century.

[illegible] to Spain are a variety of wall-tile the [illegible] the 16th and 17th centuries. These [illegible] h rather coarsely painted, and have a [illegible] predominant colour. The Casa de Pilatos and Isabel's chapel in the Alcazar palace, both at Seville, have the best specimens of these, dating about the year 1500. In other Western countries tiles have been used more for pavements than for wall-decoration.[1]

4. *Wall-Coverings of Hard Stucco, frequently enriched with Reliefs.*—The Greeks and Romans possessed the secret of making a very beautiful hard kind of stucco, creamy in colour, and capable of receiving a polish like that of marble; it would stand exposure to the weather. Those of the early Greek temples which were built, not of marble, but of stone, such as the Doric temples at Ægina, Phigaleia, Pæstum, and Agrigentum, were all entirely coated inside and out with this beautiful material—itself pleasant both in texture and hue, and an admirable surface for the further polychromatic decoration with which all Greek buildings seem to have been ornamented. Another highly artistic use of stucco among the Greeks and Romans for the interiors of buildings consisted in covering the walls and vaults with a smooth coat, on which while still wet the outlines of figures, groups, and other ornaments were sketched with a point; more stucco was then applied in lumps and rapidly modelled into delicate reliefs before it had time to set. Some tombs in Magna Græcia of the 4th century B.C. are decorated in this way with figures of nymphs, cupids, animals, and wreaths, all of which are models of grace and elegance, both in form and action, and extremely remarkable for the dexterous way in which a few rapid touches of the modelling tool or thumb have

Fig. 3.—Modelled Stucco Wall-Relief, from a Tomb in Magna Græcia. About half full-size.

produced a work of the highest artistic beauty and spirit (fig. 3). Roman specimens of this sort of decoration are very common, fine examples have been found in the baths of Titus and numerous tombs near Rome, as well

[1] See Layard, *Nineveh*; Texier, *L'Arménie*, &c.; Prisse d'Avennes and Bourgoin, *L'Art Arabe* (1869-77); Hessemer, *Arabische Bau-Verzierungen* (1853); Owen Jones, *Alhambra* (1842); Murphy, *Arabian Antiquities of Spain* (1813); *Monumentos Arquitectonicos de España* (1859-82), article "Alhambra"; Parvillée, *Architect. et décor. Turques, xv^e Siècle* (1874); Coste, *Mon. mod. de la Perse* (1867).

as in many of the houses of Pompeii. These are mostly executed with great skill and frequently with good taste, though in some cases, especially at Pompeii, elaborate architectural compositions with awkward attempts at effects of violent perspective, modelled in slight relief on flat wall-surfaces, produce a very unpleasing effect. Other Pompeian examples, where the surface is divided into flat panels, each containing a figure or group, have great merit for their delicate richness of effect, without offending against the canons of wall-decoration, one of the first conditions of which is that no attempt should be made to disguise the fact of its being a solid wall and a flat surface.

The Moslem architects of the Middle Ages, who excelled in almost all possible methods of mural decoration, made great use of stucco ornament in the most elaborate and magnificent way, both for external and internal walls. The stucco is modelled in high or low relief in great variety of geometrical patterns, of wonderful beauty and richness, alternating with bands of more flowing ornament, or long Arabic inscriptions. Many of their buildings, such as the mosque of Tulún at Cairo (879 A.D.), owe nearly all their beauty to this fine stucco work, the purely architectural shell of the structure being often quite simple and devoid of ornament. These stucco reliefs were, as a rule, further decorated with delicate painting in gold and colours, producing an effect of indescribable beauty and splendour. The Moorish tower at Segovia in Spain is a good example

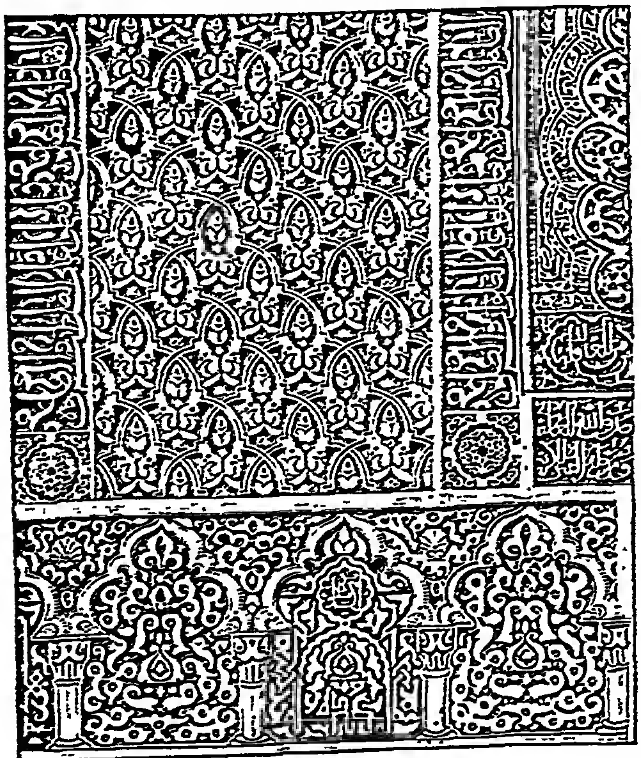

Fig. 4.—Stucco Wall-Relief, from the Alhambra.

of this class of ornament used externally. With the exception of a few bands of brick and the stone quoins at the angles, the whole exterior of the tower is covered with a network of stucco reliefs in simple geometrical patterns. The Alhambra at Granada and the Alcazar at Seville have the richest examples of this work, both in the delicate intricacy of the designs and in the brilliant colours with which they are painted. The lower part of the walls is lined with marble or tiles to a height of about 4 feet, and above that in many cases the whole surface is encrusted with these reliefs, the varied surface of which, by producing endless gradations of shadow, takes away any possible harshness or over-gaudiness from the brilliance of the gold and colours (fig. 4).[1]

During the 16th century, and even earlier, stucco wall-reliefs were used with considerable skill and decorative effect in Italy, England, and other Western countries. Perhaps the most graceful examples are the reliefs with which Vasari in the 16th century encrusted pillars and other parts of the court in the Florentine Palazzo Vecchio, built of plain stone by Michelozzi in 1454. These are very beautiful reliefs, some of flowing vines and other plants winding spirally round the columns. The English examples of this work are very effectively designed, though coarser in execution. The outside of an old half-timbered house in the market-place at Newark-upon-Trent has high reliefs in stucco of canopied figures, dating from the end of the 15th century. The counties of Essex and Suffolk are very rich in examples of this work used externally; and many 16th-century houses in England have fine internal stucco decoration, especially Hardwicke Hall (Derbyshire), one of the rooms of which has the upper part of the wall enriched with life-sized stucco figures in high relief, forming a deep frieze all round. The best English stucco work of this sort is very remarkable for its freedom and spirit of design, as well as for certain grace of line, which is a survival of the old mediæval sense of beauty, then rapidly passing away.

5. *Sgraffito.*—This is a variety of stucco work used chiefly in Italy from the 16th century downwards, and employed only for exteriors of buildings, especially the palaces of Tuscany and northern Italy. The process is this. The wall is covered with a coat of stucco made black by an admixture of charcoal; over this a second very thin coat of white stucco is laid. When it is all hard the design is produced by cutting and scratching away the white skin, so as to show the black under-coat. Thus the drawing appears in black on a white ground. This work is effective at a distance, as it requires a bold style of handling, in which the shadows are indicated by cross-hatched lines more or less near together.[2] Flowing arabesques mixed with grotesque figures occur most frequently in sgraffito. It is still largely practised in northern Italy, and has been used with success in the external decoration of the South Kensington Academy of Music.

6. *Stamped Leather.*—This was a very magnificent and expensive form of wall-hanging, chiefly used during the 16th and 17th centuries. Skins, generally of goats or calves, were well tanned and cut into rectangular shapes. They were then covered with silver leaf, which was varnished with a transparent yellow lacquer, making the silver look like gold. The skins were then stamped or embossed with patterns in relief, formed by heavy pressure from metal dies, one in relief and the other sunk. The reliefs were then painted by hand in many colours, generally brilliant in tone. Italy and Spain (especially Cordova) were important seats of this manufacture; and in the 17th century a large quantity was produced in France. Fig. 5 gives a good example of Italian stamped leather of the 16th century. In England, chiefly at Norwich, this manufacture was carried on in the 17th and 18th centuries, in many cases of very excellent design. In durability and richness of effect stamped leather surpasses most other forms of movable wall-decoration.

7. *Painted Cloth.*—Another form of wall-hanging, used most largely during the 15th and 16th centuries, and in a less extensive way a good deal earlier, is canvas painted to imitate tapestry. English mediæval inventories both

[1] It is unfortunate that the otherwise valuable work of Owen Jones on the Alhambra gives a very false and unpleasing notion of the colouring of the place.

[2] A good description of the process is given by Vasari, *Tre Arti del Disegno*, cap. xxvi.

of ecclesiastical and domestic goods frequently contain items such as these: "stayned cloths for hangings," "paynted

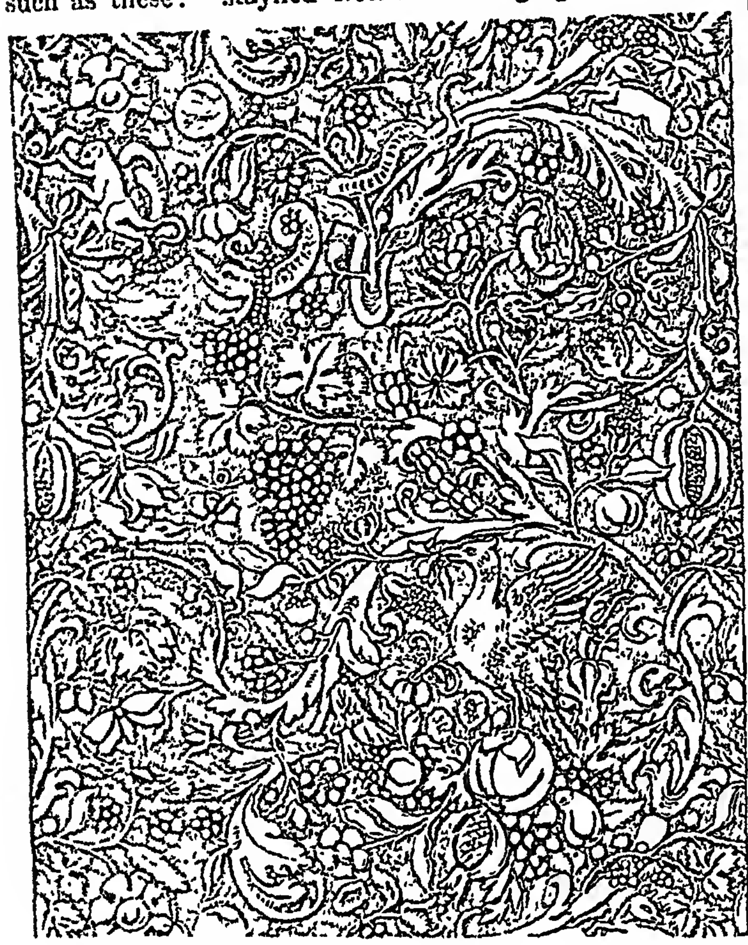

Fig. 5.—Italian Stamped Leather; 16th century.

cloths with stories and batailes," or "paynted cloths of beyond sea work," or "of Flaunder's work." Many good artists working at Ghent and Bruges during the first half of the 15th century produced very fine work of this class, as well as designs for real tapestry. Several of the great Italian artists devoted their utmost skill in composition and invention to the painting of these wall-hangings. The most important existing example is the magnificent series of paintings of the triumph of Julius Cæsar executed by Andrea Mantegna (1485-1492) for Ludovico Gonzaga, duke of Mantua, and now at Hampton Court. These are usually, but wrongly, called "cartoons," as if they were designs meant to be executed in tape try; this is not the case,

"setting" the woad or indigo vat, as well as a receipt for removing or "discharging" the colour from a cloth already dyed. Another method employed was a sort of "encaustic" process; the cloth was rubbed all over with wax, and then painted in tempera; heat was then applied so that the colours sank into the melting wax, and were thus firmly fixed upon the cloth.

8. *Printed Hangings and Wall-Papers.*—The printing of various textiles with dye-colours and mordants is probably one of the most ancient of the arts. Pliny (*H. N.*, xxxv.) clearly describes a dyeing process employed by the ancient Egyptians, in which the pattern was probably formed by printing from blocks. Various methods have been used for this work—wood blocks in relief, engraved metal plates, stencil plates, and even hand-painting; frequently two or more of these methods have been employed for the same pattern. The use of printed stuffs is of great antiquity among the Hindus and Chinese, and was certainly practised in western Europe in the 13th century, and perhaps earlier. The South Kensington Museum has 13th-century specimens of block-printed silk made in Sicily, of very beautiful design. Towards the end of the 14th century a great deal of block-printed linen was made in Flanders, and largely imported into England.

Wall-papers did not come into common use in Europe till the 18th century, though they appear to have been used much earlier by the Chinese. A few rare examples exist in England which may be as early as the 16th century; these are imitations, generally in flock, of the fine old Florentine and Genoese cut velvets, and hence the style of the design in no way shows the date of the wall-paper, the same traditional patterns being reproduced for many years with little or no change. Machinery enabling paper to be made in long strips was not invented till the end of the last century, and up to that time wall-papers were printed on small square pieces of hand-made paper, difficult to hang, disfigured by numerous joints, and comparatively costly; on these accounts wall-papers were slow in superseding the older and more magnificent modes of mural decoration, such as wood-panelling, painting, tapestry, stamped leather, and painted cloth. A little work by Jackson of Battersea, printed in London in 1744, throws some light on the use of wall-papers at that time. He gives reduced copies of his designs, mostly taken from Italian pictures or antique sculpture during his residence in Venice. Instead of flowing patterns covering the wall, his designs are all pictures—landscapes, architectural scenes, or statues—treated as panels, with plain paper or painting between. They are all printed in oil, with wooden blocks worked with a rolling press, apparently an invention of his own. They are all in the worst possible taste, and yet are offered as great improvements on the Chinese papers which he says were then in fashion.

The method of printing wall-papers of the better sort is probably the same now that it has always been. Wooden blocks with the design cut in relief, one for each colour, are applied by hand, after being dipped in an elastic cloth sieve charged with wet tempera pigment, great care being taken to lay each block exactly on the right place, so that the various colours may "register" or fit together. In order to suit the productions of the paper-mills these blocks are made, in England 21 inches wide, and in France 18 inches wide; the length of the block is limited to what the workman can easily lift with one hand,—2 feet being about the limit, as the blocks are necessarily thick, and in many cases made heavier by being inlaid with copper, especially the thin outlines, which, if made of wood, would not stand the wear and tear of printing. In "flock" and gold or silver printing the design is first printed in strong size; the flock (finely cut wool of the required colour), or metallic powder is then sprinkled by hand all over the paper; it adheres only to the wet size, and is easily shaken off the ground or unsized part. If the pattern is required to stand out in some relief this process is repeated several times, and the whole paper then rolled to compress the flock. Cheaper sorts of paper are printed by machinery, the design being cut on the surface of wooden rollers, under which

the paper passes. The chief drawback to this process is that all the colours are applied rapidly one after the other, without allowing each to dry separately, as is done in hand printing. A somewhat blurred appearance is the usual result.

Though at first wall-papers were a mere makeshift and feeble imitation of rich textiles, yet, with a good feeling for the harmonies of colour and a regard for the technical necessities of the process, very rich and beautiful effects may be produced at a comparatively small cost if hand-printing be adopted. Imitations of stamped leather are now produced with great success, though of inferior durability. Very thick tough paper is used for this, and treated in the same way as the real skins mentioned above. Fig. 6 is a good English example of 18th-century wall-

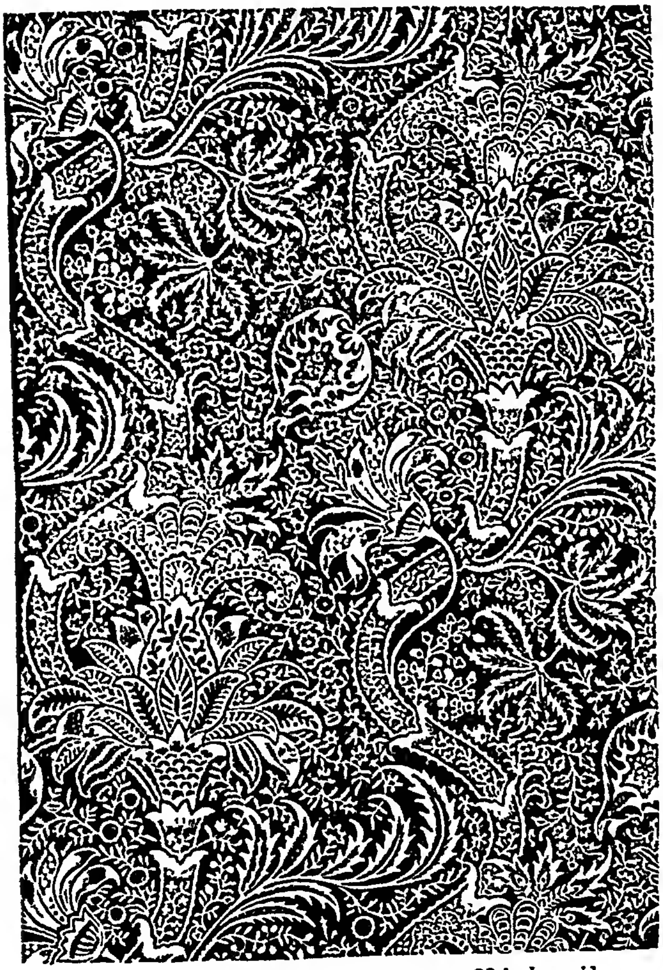

FIG. 6.—Early 18th-century Wall-Paper. 22 inches wide.

paper printed on squares of stout hand-made paper 22 inches wide. The design is apparently copied from an Indian chintz.

PAINTING.

This is naturally the most important and the most widely used of all forms of wall-decoration, as well as perhaps the earliest.

Egyptian Paintings.—Egypt is the chief storehouse of ancient specimens of this, as of almost all the arts. Owing to the intimate connexion between the sculpture and painting of early times, the remarks above both as to subjects and treatment under the head of Egyptian wall-sculpture will to a great extent apply also to the paintings. It is a very important fact, and one which testifies clearly to the enormous antiquity of Egyptian civilization, that the earliest paintings, dating more than 4000 years before our era, are also the cleverest both in drawing and execution. In later times the influence of Egyptian art, especially in painting, was very important among even very distant nations. In the 6th century B.C. Egyptian colonists, introduced by Cambyses into Persepolis, largely influenced the painting and sculpture of the great Persian empire and throughout the valley of the Euphrates. In a lesser degree the art of Babylon and Nineveh had felt considerable Egyptian influence several centuries earlier. The same influence affected the early art of the Greeks and the Etrurians, and it was not till the middle of the 5th century B.C. that the further development and perfecting of art in Greece obliterated the old traces of Egyptian mannerism. After the death of Alexander the Great, when Egypt came into the possession of the Lagidæ (320 B.C.), the tide of influence flowed the other way, and Greek art modified though it did not seriously alter the characteristics of Egyptian painting and sculpture, which still retained much of their early formalism and severity. And yet the increased sense of beauty, especially in the human face, derived from the Greeks was counterbalanced by loss of vigour and force; art under the Ptolemies ceased to have a real life and became a mere dull copyism of earlier traditions.

The general scheme of mural painting in the buildings of ancient Egypt was very complete and magnificent. Columns, mouldings, and other architectural features were enriched with patterns in brilliant colours; the flat wall-spaces were covered with figure-subjects, generally in horizontal bands, and the ceilings were richly ornamented with sacred symbols, such as the vulture, or painted blue and studded with gold stars to symbolize the sky. The wall-paintings are executed in tempera on a thin skin of fine lime, laid over the brick, stone, or marble to form a smooth and slightly absorbent coat to receive the pigments, which were most brilliant in tone and of great variety of tint. Not employing fresco, the Egyptian artists were not restricted to "earth colours," but occasionally used purples, pinks, and greens which would have been destroyed by fresh lime. The blue used is a very beautiful colour, and is generally laid on in considerable body—it is frequently a "smalt" or deep-blue glass, coloured by copper oxide, finely powdered. Red and yellow ochre, carbon-black, and powdered chalk-white are most largely used. Though in the paintings of animals and birds considerable realism is often seen (fig. 7), yet for human figures certain

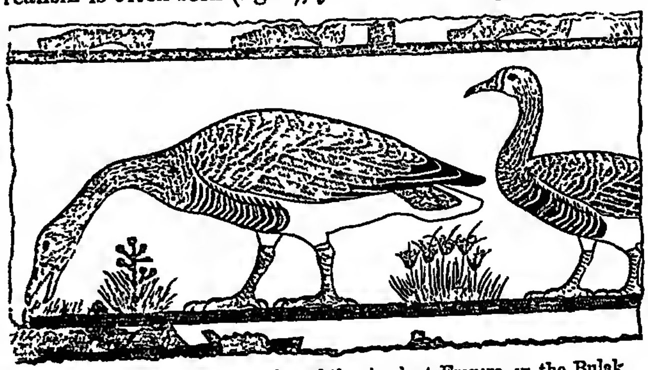

FIG. 7.—Egyptian Wall-Painting of the Ancient Empire, in the Bulak Museum. Taken from Loftie's *Ride in Egypt*.

conventional colours are employed, *e.g.*, white for females' flesh, red for the males, or black to indicate people of negro race. Heads are painted in profile, and little or no shading is used. Considerable knowledge of harmony is shown in the arrangement of the colours; and otherwise harsh combinations of tints are skilfully softened and brought into keeping by thin separating lines of white or yellow. Though at first sight the general colouring, if seen in a museum, may appear crude and gaudy, yet it should be remembered that the internal paintings were much softened by the very dim light that was sparingly

admitted into Egyptian buildings, and those outside were subdued by contrast with the brilliant blue sky and glowing sunshine under which they were always seen.[1]

Etruscan Painting.—The rock-cut sepulchres of the Etrurians (see ETRURIA, vol. viii. p. 645) supply the only existing specimens of their mural painting; and, unlike the tombs of Egypt, only a small proportion appear to have been decorated in this way. The actual dates of these paintings are very uncertain, but they range possibly from about the 8th century B.C. down to almost the Christian era. The tombs which possess these paintings are mostly square-shaped rooms, with slightly-arched or gabled roofs, excavated in soft sandstone or tufa hillsides. The earlier ones show distinct Egyptian influence alike in drawing and in composition: they are very broadly designed with flat unshaded tints, the faces in profile, except the eyes, which are drawn as if seen in front. Colours, as in Egypt, are used conventionally—male flesh red, white or pale yellow for the females, black for demons. In one respect these paintings differ from those of the Egyptians; very few colours are used—red, brown, and yellow ochres, carbon-black, lime or chalk-white, and occasionally blue are the only pigments. The rock-walls are prepared by being covered with a thin skin of lime stucco, and lime or chalk is mixed in small quantities with all the colours; hence the restriction to "earth pigments," made doubly necessary by the constant dampness of these subterranean chambers. The process employed was in fact a kind of *fresco*, though the stucco ground was not applied in small patches only sufficient for the day's work; the dampness of the rock was enough to keep the stucco skin moist, and so allow the necessary infiltration of colour from the surface. Many of these paintings when first discovered were quite fresh in tint and uninjured by time, but they are soon dulled by exposure to light. In the course of centuries great changes of style naturally took place; the early Egyptian influence, probably brought to Etruria through the Phœnician traders, was succeeded by an even more strongly-marked Greek influence—at first archaic and stiff, then developing into great beauty of drawing, and finally yielding to the Roman spirit, as the degradation of Greek art advanced under their powerful but inartistic Roman conquerors.

Throughout this succession of styles—Egyptian, Greek, and Græco-Roman—there runs a distinct undercurrent of individuality due to the Etruscans themselves. This appears not only in the drawing but also in the choice of subjects. In addition to pictures of banquets with musicians and dancers, hunting and racing scenes, the workshops of different craftsmen and other domestic subjects, all thoroughly Hellenic in sentiment, other paintings occur which are very un-Greek in feeling. These represent the judgment and punishment of souls in a future life. Mantus, Charun, and other infernal deities of the Rasena, hideous in aspect and armed with hammers, or furies, depicted as black bearded demons winged and brandishing live snakes, terrify or torture shrinking human souls. Others, and not the earliest in date, represent human sacrifices, such as those at the tomb of Patroclus—a class of subjects which, though Homeric, appears but rarely to have been selected by Greek painters. The constant import into Etruria of large quantities of fine Greek painted vases appears to have largely contributed to keep up the supremacy of Hellenic influence during many centuries, and by their artistic superiority to have prevented the development of a more original and native school of art. Though we now know Etruscan painting only from the tombs, yet Pliny mentions (*H. N.*, xxxv. 3) that fine wall-paintings existed in his time, with colours yet fresh, on the walls of ruined temples at Ardea and Lanuvium, executed, he says, before the founding of Rome. As before mentioned, the actual dates of the existing paintings are very uncertain. It cannot therefore be positively asserted that any existing specimens are much older than 600 B.C., though some, especially at Veii, certainly appear to have the characteristics of more remote antiquity. The most important of these paintings have been discovered in the cemeteries of Veii, Cære, Tarquinii, Vulci, Cervetri, and other Etruscan cities.[2]

Greek Painting.—This is a very obscure subject, for, although Strabo, Pliny, Pausanias, and others have left us minute descriptions of Greek paintings and ample accounts of painters and styles, yet of the pictures themselves almost nothing now remains. Even in Egypt the use of colour does not appear to have been more universal than it was among the Greeks, who applied it freely to their marble statues and reliefs, the whole of their buildings inside and out, as well as for the decoration of flat wall-surfaces. They appear to have cared but little for pure form, and not to have valued the delicate ivory-like tint and beautiful texture of their fine Pentelic and Parian marbles, except as a ground for coloured ornament. A whole class of artists, called ἀγαλμάτων ἐγκαυσταί, were occupied in colouring marble sculpture, and their services were very highly valued.[3] In some cases, probably for the sake of hiding the joints and getting a more absorbent surface, the marble, however pure and fine in texture, was covered with a thin skin of stucco made of mixed lime and powdered marble. Among the extremely rare specimens of Greek painting still existing, the most important is an alabaster sarcophagus, found in a tomb near Corneto, and now in the Etruscan museum at Florence.[4] This is decorated outside with very beautiful and purely Greek paintings, executed on a stucco skin as hard and smooth as the alabaster itself. The pictures represent combats of the Greeks and Amazons, drawn with marvellous beauty of outline and grace of movement and composition. The colouring, though rather brilliant, is very simply treated, and the figures are kept strictly to one plane without any attempt at complicated perspective. Other most valuable specimens of Greek art, found at Herculaneum and now in the Naples museum, are some small paintings, one of girls playing with dice, another of Theseus and the Minotaur. These are painted with miniature-like delicacy on the bare surface of marble slabs; they are almost monochromatic, and are of the highest beauty both in drawing and in their skilfully-modelled gradations of shadow—quite unlike any of the Greek vase-paintings. The first-mentioned painting is signed ΑΛΕΞΑΝΔΡΟΣ ΑΘΗΝΑΙΟΣ. It is probable that the strictly archaic paintings of the Greeks, such as those of Polygnotus in the 5th century B.C., executed with few and simple colours, had much resemblance to those on vases, but Pliny is certainly wrong when he asserts that, till the time of Apelles (*c.* 350-310 B.C.), the Greek painters only used black, white, red, and

[1] See Champollion, *Panthéon Égyptien* (1825); De Joannis, *Peintures murales . . . des Égyptiens*; Bicchy, *La Peinture chez les Égyptiens* (1868); Lenormant, *Antiquités Égyptiennes*; Lepsius, *Denkmäler aus Aegypten*; Wilkinson, *Anc. Egypt.*; *Descr. de l'Égypte* (Paris, 1821, &c.); Perrot et Chipiez, *L'Art d'Égypte* (1880), and other works on Egypt.

[2] See Dennis, *Cities and Cemeteries of Etruria* (1878); Golini, *Pitture murali Etrusche*; Micali, *Mon. inediti*; *Mon.* and *Ann. d. Inst. Arch.* (Rome, various years); Canina, *L'antica Etruria* (1846, et sq.); Bartoli, *Sepolchri Rom. ed Etrus.* (1727); Müller, *Etrusker*, and other works; Helbig, *Pitture Cornetane* (1863); Inghirami, *Mon. Etruschi* (1821-26); Byres, *Sepulchral Caverns of Tarquinia* (1842); and Raoul Rochette, *Mon. d'Antiquité Grecque, Etrusque, et Romaine* (1833).

[3] This process, *circumlitio*, is mentioned by Pliny (*H. N.*, xxxv. 40).

[4] See *Mon. Inst. Arch.*, Rome, ix. plate 60.

yellow.[1] Judging from the peculiar way in which the Greeks and their imitators the Romans used the names of colours, it appears that they paid more attention to *tones* and *relations* of colour than to actual hues. Thus most Greek and Latin colour-names are now quite untranslatable. Homer's "wine-like sea" (οἶνοψ), Sophocles's "wine-coloured ivy" (*Œd. Col.*), and Horace's "purpureus olor" probably refer less to what we should call colour than to the chromatic strength of the various objects and their more or less strong powers of reflecting light, either in motion or when at rest. Nor have we any word like Virgil's "flavus," which could be applied both to a lady's hair and to the leaf of an olive-tree.[2]

During the best periods of Greek art the favourite classes of subjects were scenes from poetry, especially Homer, and contemporary history. The names πιναχοθήκη and στοὰ ποικίλη were given to many public buildings from their walls being covered with paintings. Additional interest was given to the historical subjects by the introduction of portraits; *e.g.*, in the great picture of the battle of Marathon (490 B.C.), on the walls of the στοὰ ποικίλη in Athens, portraits were given of the Greek generals Miltiades, Callimachus, and others. This picture was painted about forty years after the battle by Polygnotus and Micon. One of the earliest pictures recorded by Pliny (xxxv. 8) represented a battle of the Magnesians (c. 716 B.C.); it was painted by Bularchus, a Lydian artist, and bought at a high price by King Candaules. Many other important Greek historical paintings are mentioned by Pausanias and earlier writers. The Pompeian mosaic of the defeat of the Persians by Alexander is probably a Romanized copy from some celebrated Greek painting; it obviously was not designed for mosaic work.

Landscape painting appears to have been unknown among the Greeks, even as a background to figure subjects. The poems especially of Homer and Sophocles show that this was not through want of appreciation of the beauties of nature, but partly, probably, because the main object of Greek painting was to tell some definite story, and also from their just sense of artistic fitness, which prevented them from attempting in their mural decorations to disguise the flat solidity of the walls by necessarily delusive effects of aerial perspective and distance.

It is interesting to note that even in the time of Alexander the Great the somewhat archaic works of the earlier painters were still highly appreciated. In particular Aristotle gives high praise to Polygnotus, both for his power of combining truth with idealization in his portraits and for his skill in depicting men's mental characteristics; on this account he calls him ὁ ἠθογράφος. Lucian too is no less enthusiastic, and praises Polygnotus alike for his grace, drawing, and colouring. Later painters, such as Zeuxis and Apelles, appear to have produced easel pictures more than mural paintings, and these, being easy to move, were mostly carried off to Rome by the early emperors. Hence Pausanias, who visited Greece in the time of Hadrian, mentions but few works of the later artists. Owing to the lack of existing specimens of Greek painting it would be idle to attempt an account of their technical methods, but no doubt those employed by the Romans described below were derived with the rest of their art from the Greeks. Speaking of their stucco, Pliny refers its superiority over that made by the Romans to the fact that it was always made of lime at least three years old, and that it was well mixed and pounded in a mortar before being laid on the wall; he is here speaking of the thick stucco in many coats, not of the thin skin mentioned above as being laid on marble.

Greek mural painting, like their sculpture, was chiefly used to decorate temples and public buildings, and comparatively rarely either for tombs[3] or private buildings,—at least in the days of their early republican simplicity. They were in the true sense of the word works of monumental art, and were no doubt designed and executed with that strict self-restraint and due subordination to their architectural surroundings which we see so strongly marked in all Greek sculpture of the best periods.[4]

Roman Painting.—A very large number of Roman mural paintings now exist, of which by far the greatest quantity was discovered in the private houses and baths of Pompeii, nearly all dating between 63 A.D., when the city was ruined by an earthquake, and 79 A.D., when it was buried by Vesuvius. A catalogue of these and similar paintings from Herculaneum and Stabiæ, compiled by Professor Helbig, comprises 1966 specimens. The excavations in the baths of Titus and other ancient buildings in Rome, made in the early part of the 16th century, excited the keenest interest and admiration among the painters of that time, and very largely influenced the later art of the Renaissance. These paintings, especially the "grotesques" or fanciful patterns of scroll-work and pilasters mixed with semi-realistic foliage and figures of boys, animals, and birds, designed with great freedom of touch and inventive power, seem to have thoroughly fascinated Raphael during his later period, and many of his pupils and contemporaries. The "loggie" of the Vatican and of the Farnesina palace are full of carefully-studied 16th-century reproductions of these highly-decorative paintings. Of late years the excavations on the Palatine and in the garden of the Farnesina in Rome have brought to light some mural paintings of the 1st century of our era, perhaps superior in execution even to the best of the Pompeian series.

The range of subjects found in Roman mural paintings is very large—mythology, religious ceremonies, genre, still life, and even landscape (the latter generally on a small scale, and treated in an artificial and purely decorative way), and lastly history. Pliny mentions several large and important historical paintings, such as those with which Valerius Maximus Messala decorated the walls of the Curia Hostilia, to commemorate his own victory over Hiero II. and the Carthaginians in Sicily in the 3d century B.C. The earliest Roman painting recorded by Pliny was by Fabius, surnamed Pictor, on the walls of

[1] Pliny's remarks on subjects such as this should be received with caution. He was neither a scientific archæologist nor a practical artist.

[2] So also a meaning unlike ours is attached to Greek technical words —by τόνος they meant, not "tone," but the gradations of light and shade, and by ἁρμογή the relations of colour. See Pliny, *H. N.*, xxxv. 5; and Ruskin, *Mod. Painters*, pt. iv. cap. 13.

[3] One instance only of a tomb-painting is mentioned by Pausanias (vii. 22). Some fine specimens have recently been discovered in the Crimea, but not of a very early date; see Stephani, *Compte rendu*, &c., St Petersburg, 1878, &c.

[4] Some of the following works contain accounts of the painting of the Romans as well as of the Greeks:—Letronne, *La Peint. histor. murale* (1835); Hittorf, *L'Arch. polychrome chez les Grecs* (1851); Wornum, *Hist. of Painting* (1847); Newton, *Lect. on the Painting of the Ancients, deliv. at Univ. Coll. Lon.* (1882); Hermann, *Die Polygnotischen Gemälde*; Lenormant, *Les Peintures de Polygnote* (1864); Winckelmann, *Storia dell' Arti* (1784); Muller, *Handbuch d. Archäol. der Kunst*, &c. (1830); Pliny, *H. N.*, Books xxxv., xxxvi.; Pausanias, x. 25-31,—description of paintings in the Lesche at Delphi,—and various other passages throughout his work; Artaud de Montor, *Peintres primitifs* (1841-43); Humphrey Davy, "Colours used by the Ancients," *Trans. Roy. Soc.* (1815, pp. 97-124); Bluemner, *Gewerbe u. Kunst bei Griechen u. Römern* (1879); Brunn, *Gesch. der Griech. Künstler* (1853-56); Durand, *Hist. de la Peinture Ancienne* (1725); Meyer, *Gesch. der bildenden Künste* (1824); Raoul Rochette, *La Peinture des Grecs* (1840), and *Mon. d'Antiq.* (1833); Poynter, *Decorative Art*, series of lectures published by the Society for the Protection of Ancient Buildings (1882).

the temple of Salus, executed about 300 B.C. (*H. N.*, xxxv. 4).

Unfortunately no existing Roman paintings seem to be earlier in date than the Christian era, and all belong to a period of decline in art. Pliny (xxxv. 1) laments the fact that the wealthy Romans of his time preferred the costly splendours of marble and porphyry wall-linings to the more artistic decoration of paintings by good artists. Historical painting seems then to have gone out of fashion; among the numerous specimens now existing very few from

FIG. 8.—One Figure from a Pompeian Wall-Painting—Ariadne and Dionysus. Now in the Naples Museum.

Pompeii represent historical subjects; one has the scene of Masinissa and Sophonisba before Scipio, and another of a riot between the people of Pompeii and Nocera, which happened 59 A.D.

Mythological scenes, chiefly from Greek sources, occur most frequently: the myths of Eros and Dionysus are especial favourites. Only five or six relate to purely Roman mythology. We have reason to think that some at least of the Pompeian pictures are copies, probably at third or fourth hand, from celebrated Greek originals. The frequently repeated subjects of Medea meditating the murder of her children and Iphigenia at the shrine of the Tauric Artemis suggest that the motive and composition were taken from the celebrated originals of these subjects by Timanthes. Those of Io and Argus, the finest example of which is in the Palatine "villa of Livia," and of Andromeda and Perseus, often repeated on Pompeian walls, may be from the originals by Nicias.[1]

In many cases these mural paintings are of high artistic merit, though they are probably not the work of the most distinguished painters of the time, but rather of a humbler class of decorators, who reproduced, without much original invention, stock designs out of some pattern-book. They are, however, all remarkable for the rapid skill and extreme "verve" and freedom of hand with which the designs are, as it were, flung on to the walls with few but very effective touches. Though in some cases the motive and composition are superior to the execution, yet many of the paintings are remarkable both for their realistic truth and technical skill. The great painting of Ceres from Pompeii, now in the Naples museum, is a work of the highest merit—the simple grandeur of the drawing and the delicate modelling of the flesh, executed in the easiest and most direct manner possible, are alike admirable. The round juiciness of the fruit in her basket, rapidly painted with a few telling strokes of the brush, recalls to mind in effect, though not in execution, the startling realism of the Dutch painters of still life, who laboured painfully to gain the effect produced with such rapidity and ease by the Roman artist. Fig. 8, from a Pompeian picture, is a fine example of good modelling of flesh.

In the usual scheme of decoration the broad wall-surfaces are broken up into a series of panels by pilasters, columns, or other architectural forms. Some of the panels contain pictures with figure-subjects; others have conventional ornament, or hanging festoons of fruit and flowers. The lower part of the wall is painted one plain colour, forming a dado; the upper part sometimes has a well-designed frieze of flowing ornaments. In the better class of painted walls the whole is kept flat in treatment, and is free from too great subdivision, but in many cases great want of taste is shown by the introduction of violent effects of architectural perspective, and the space is broken up in a disagreeable way by complicated schemes of design, studded with pictures in varying scales which have but little relation to their surroundings. The colouring is on the whole very pleasant and harmonious—quite unlike the usual chromolithographic copies. Black, yellow, or a rich deep red are the favourite colours for the main ground of the walls, the pictures in the panels being treated separately, each with its own background.

Technical Methods of the Romans.—Much has been written on this subject, and the most varying opinions have been expressed. The real fact appears to be that several methods were employed in each painting. First, the ground of the required colour was laid on while the stucco was still moist. This ground therefore was true fresco or "fresco buono." On this, when dry, the various pictures and ornaments were painted in tempera. That the pictures themselves were not in true fresco is shown: (1) because the coloured ground always exists *under* the pictures; (2) by the wide distances apart of the "fresco edges" or joinings in the stucco, showing that a much larger area of stucco was applied at once than could have been covered with the frequently elaborate paintings before the stucco was dry; (3) by the fact that many of the brilliant pigments were not such as could have been used upon moist stucco. The next point is how these tempera paintings on the fresco ground were *fixed* so as to last for nearly eighteen hundred years uninjured by the damp which necessarily soaked through into the soil and ashes in which they were buried. This was probably effected by the "encaustic" process (ἔγκαυσις). When the painting was finished and dry, hot melted wax was brushed all over it; and then a red-

[1] See Newton, *Lect. on Painting of the Ancients*, 1882.

hot iron or brazier of burning charcoal was held near the face of the wall till, bit by bit, all the wax disappeared from the surface and soaked thoroughly into the absorbent stucco,—thus fixing the pigments with a vehicle that could stand the effects of damp. This application of hot wax appears to have been repeated more than once. The extreme smoothness of the fresco ground *under* the tempera pictures seems to show that the ground itself was both waxed and polished *before* the pictures were painted over it. By another method of encaustic the pigments themselves were mixed with hot wax, probably rendered more fluid and easy to work by the addition of some mineral spirit or essential oil. The final application of heat to the painted surface blended the colours together and fixed them on and into the absorbent stucco ground. Vitruvius (vii. 9) describes the former process, in which the wax was applied after the colours were laid on the wall. According to him this was necessary in order to prevent the painted surface becoming patchy, especially in the case of the red ground made of vermilion, an oxide of mercury. This, as well as the evidence of the paintings themselves, shows that Pliny is mistaken in asserting that encaustic work could not be used for walls.[1] Vitruvius (vii.) also gives an interesting account of the great care that was needed in preparing stucco for painting. Three coats of old slaked lime and sand were first to be laid, and then three more coats mixed with pounded white marble, each coat of more finely powdered marble than the one beneath; the last coat was to be polished till it gave a reflexion like a mirror. Damp or external walls were to be built hollow, and the cavity ventilated; this was sometimes done, *e.g.*, in the Palatine villa, by facing the wall inside with hollow bricks or tiles, on which the stucco was laid. Vitruvius, who probably died shortly before the Christian era, laments the decay of taste in his time, much as Pliny does; he specially deprecates the use of gaudy red lead, and the sham architectural paintings in which candelabra, reeds, and other incongruities are made to support heavy cornices and roofs of buildings. He complains also of the novel taste for expensive but inartistic colours, such as purple and azure.[2]

Early Christian Mural Paintings in Italy.—A very interesting series of these exists in various catacombs, especially those of Rome and Naples. They are of great value, both as an important link in the history of art and also as throwing considerable light on the mental state of the early Christians, which was distinctly influenced by the older faith. Thus in the earlier paintings of about the 4th century we find Christ represented as a beardless youth, beautiful as the artist could make him, with a lingering tradition of Greek idealization, in no degree like the "Man of Sorrows" of mediæval painters, but rather a kind of genius of Christianity in whose fair outward form the peace and purity of the new faith were visibly symbolized, just as certain distinct attributes were typified in the persons of the gods of ancient Greece. The favourite early subject, Christ the Good Shepherd (fig. 9), is represented as Orpheus playing on his lyre to a circle of beasts, the pagan origin of the picture being shown unmistakably by the Phrygian cap and by the presence of lions, panthers, and other incongruous animals among the listening sheep. In other cases Christ is depicted standing with a sheep borne on his shoulders like Hermes Criophoros or Hermes Psychopompos—favourite Greek subjects, especially the former, a statue of which Pausanias (ix. 22) mentions as existing at Tanagra in Bœotia. Here again the pagan origin of the type is shown by the presence in the catacomb paintings of the pan-pipes and pedum, special attributes of Hermes, but quite foreign to the notion of Christ. Though in a degraded form, a good deal survives in some of these paintings, especially in the

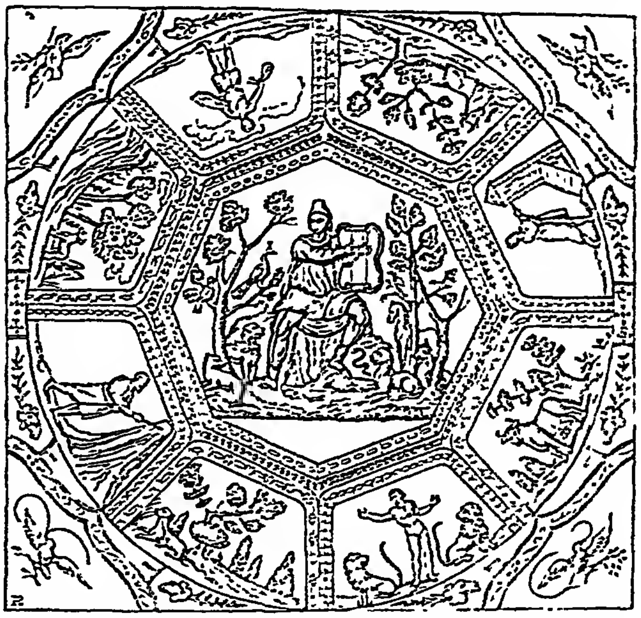

FIG. 9.—Painted Vault from the Catacombs of St Callixtus, Rome. In the centre Orpheus, to represent Christ the Good Shepherd, and round are smaller paintings of various types of Christ.

earlier ones, of the old classical grace of composition and beauty of drawing, notably in the above-mentioned representations where old models were copied without any adaptation to their new meaning. Those of the 5th and 6th centuries still follow the classical lines, though in a rapidly deteriorating style, until the introduction of a foreign—the Byzantine—element, which created a fresh starting-point on quite different lines. The old naturalism and survival of classical freedom of drawing is replaced by stiff, conventionally hieratic types, very superior in dignity and strength to the feeble and spiritless compositions produced by the extreme degradation into which the native art of Rome had fallen. The designs of this second period of Christian art are very similar to those of the mosaics, such as many at Ravenna, and also to the magnificently illuminated MSS. on which the utmost skill and labour of the time were lavished. For some centuries there was but little change or development in this Byzantine style of art, so that it is impossible in most cases to be sure from mere internal evidence of the date of any painting. This to some extent applies also to the works of the earlier or pagan school, though, roughly speaking, it may be said that the least meritorious pictures are the latest in date.

These catacomb paintings range over a long space of time; some may possibly be of the 1st or 2d century, *e.g.*, those in the cemetery of Domitilla, Rome; others are as late as the 9th century, *e.g.*, some full-length figures of St Cornelius and St Cyprian in the catacomb of St Callixtus, under which earlier paintings may be traced. In execution they somewhat resemble the Etruscan tomb-paintings; the walls of the catacomb passages and chambers, excavated in soft tufa, are covered with a thin skin of white stucco, and on that the mural and ceiling paintings are simply executed in earth colours. The favourite subjects of the earliest paintings are scenes from the Old Testament which were supposed to typify events in the life of Christ, such as the sacrifice of Isaac (Christ's death), Jonah and the whale (the resurrection), Moses striking the rock, or pointing to the manna (Christ the water of life, and the Eucharist), and many others. The later paintings deal more with later subjects, either events

[1] His remarks on the subject (xxxv. 11) are quite unintelligible.

in Christ's life or figures of saints and the miracles they performed. A very fine series of these exists in the lower church of S. Clemente in Rome, apparently dating from the 6th to the 10th centuries; among these are representations of the passion and death of Christ—subjects never chosen by the earlier Christians, except as dimly foreshadowed by the Old Testament types. When Christ Himself is depicted in the early catacomb paintings it is in glory and power, not in His human weakness and suffering.

Other early Italian paintings exist on the walls of the church of the Tre Fontane near Rome, and in the Capella di S. Urbano alla Caffarella, executed in the early part of the 11th century. The atrium of S. Lorenzo fuori le mura, Rome, and the church of the Quattro Santi Incoronati have mural paintings of the first half of the 13th century, which show no artistic improvement over those at S. Clemente four or five centuries older.

It was not in fact till the second half of the 13th century that stiff traditional Byzantine forms and colouring began to be superseded by the revival of native art in Italy by the painters of Florence, Pisa, and Siena (see FRESCO). During the first thirteen centuries of the Christian era mural painting appears to have been for the most part confined to the representation of sacred subjects. It is remarkable that during the earlier centuries council after council of the Christian church forbade the painting of figure-subjects, and especially those of any Person of the Trinity; but it was quite in vain. The double desire, both for the artistic effect of painted walls and for the religious teaching afforded by the pictorial representation of sacred scenes and the celebration of the sacraments, was too strong. In spite of the zeal of bishops and others, who sometimes with their own hands defaced the pictures of Christ on the walls of the churches, in spite of threats of excommunication, the forbidden paintings by degrees became more numerous, till the walls of almost every church throughout Christendom were decorated with whole series of pictured stories. The useless prohibition was becoming obsolete when, towards the end of the 4th century, the learned Paulinus, bishop of Nola, ordered the two basilicas which he had built at Fondi and Nola to be adorned with wall-paintings of sacred subjects, with the special object, as he says, of instructing and refining the ignorant and drunken people. These painted histories were in fact the books of the unlearned, and we can now hardly realize their value and importance as the chief mode of religious teaching in ages when none but the clergy could read or write.[1]

English Mural Painting.—During the Middle Ages, just as long before among the ancient Greeks, coloured decoration was used in the widest possible manner, not only for the adornment of flat walls, but also for the enrichment of sculpture and all the fittings and architectural features of buildings, whether the material to be painted was plaster, stone, marble, or wood. It was only the damp and frosts of northern climates that to some extent limited the external use of colour to the less exposed parts of the outsides of buildings. The varying tints and texture of smoothly-worked stone appear to have given no pleasure to the mediæval eye; and in the rare cases in which the poverty of some country church prevented its walls from being adorned with painted ornaments or pictures the whole surface of the stone-work inside, mouldings and carving as well as flat wall-spaces, was covered with a thin coat of whitewash. Internal rough stonework was invariably concealed by stucco, forming a smooth ground for possible future paintings. Unhappily the ignorant barbarity of the 19th century has in the case of most English cathedrals and parish churches stripped off the internal plaster, often laying bare rubble walls of the roughest description, never meant to be exposed, and has scraped and rubbed the surface of the masonry and mouldings down to the bare stone. In this way a great proportion of mural paintings have been destroyed, though many in a more or less mutilated state still exist in England. It is difficult (and doubly so since the so-called "restoration" of most old buildings) to realize the splendour of effect once possessed by every important mediæval church. From the tiled floor to the roof all was one mass of gold and colour. The brilliance of the mural paintings and richly-coloured sculpture and mouldings was in harmony with the splendour of the oak-work—screens, stalls, and roofs—all richly decorated with gilding and painting, while the light, passing through stained glass, softened and helped to combine the whole into one even mass of extreme decorative effect. Colour, and not in dull tints, was boldly applied everywhere, and thus the patchy effect was avoided which is so often the result of the modern timid and partial use of painted ornament. Even the figure-sculpture was painted in a strong and realistic manner, sometimes by a wax encaustic process, probably the same as the *circumlitio* of classical times. In the accounts for expenses in decorating Orvieto cathedral wax is a frequent item among the materials used for painting. In one place it is specially mentioned that wax was supplied to Andrea Pisano (in 1345) for the decoration of the beautiful reliefs in white marble on the lower part of the west front.

General Schemes of Mural Painting.—From the 11th to the 16th century the lower part of the walls, generally 6 to 8 feet from the floor, was painted with a dado—the favourite patterns till the 13th century being either a sort of sham masonry with a flower in each rectangular space (fig. 10), or a conventional representation of a curtain with regular folds stiffly treated (Plate I.). Above this dado ranges of pictures with figure-subjects were painted in tiers one above the other, each picture frequently surrounded by a painted frame with arch and gable of architectural design.

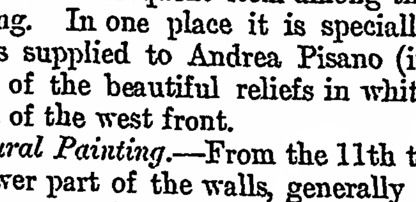

FIG. 10.—Wall-Painting, of the 13th century. "Masonry pattern."

Painted bands of chevron or other geometrical ornament till the 13th century, and flowing ornament afterwards, usually divide the tiers of pictures horizontally and form the top and bottom boundaries of the dado. In the case of a church, the end walls usually have figures to a larger scale. On the east wall of the nave over the chancel arch there was generally a large painting of the "Doom" or Last Judgment. One of the commonest subjects is a colossal figure of St Christopher (fig. 11), usually on the nave wall opposite the principal entrance,—selected because the sight of a picture of this saint was supposed to bring good luck for the rest of the

day. Figures were also often painted on the jambs of the windows and on the piers and soffit of the arches, especially that opening into the chancel.

FIG. 11.—Wall-Painting of St Christopher. Large life-size.

The little Norman church at Kempley in Gloucestershire (date about 1100) has perhaps the best-preserved specimen of the complete early decoration of a chancel.[1] The north and south walls are occupied by figures of the twelve apostles in architectural niches, six on each side. The east wall had single figures of saints at the sides of the central window, and the stone barrel vault is covered with a representation of St John's apocalyptic vision—Christ in majesty surrounded by the evangelistic beasts, the seven candlesticks, and other figures. The chancel arch itself and the jambs and mouldings of the windows have stiff geometrical designs, and over the arch, towards the nave, is a large picture of the "Doom." The whole scheme is very complete, no part of the internal plaster or stone-work being undecorated with colour. Though the drawing is rude, the figures and their drapery are treated broadly and with dignity. Simple earth colours are used, painted in tempera on a plain white ground, which covers alike both the plaster of the rough walls and the smooth stone of the arches and jambs.

In the 13th century the painters of England reached a very high point of artistic power and technical skill, so much so that at that time paintings were produced by native artists quite equal, if not superior, to those of the same period anywhere on the Continent, not excepting even Italy. The central paintings on the walls of the chapter-house and on the retable of the high altar of Westminster Abbey are not surpassed by any of the smaller works even of such men as Cimabue and Duccio di Buoninsegna, who were living when these Westminster paintings were executed. Unhappily, partly through the poverty and anarchy brought about by the French wars and the Wars of the Roses, the development of art in England made but little progress after the beginning of the 14th century, and it was not till a time when the renaissance of art in Italy had fallen into a state of degradation and decay that its influence reached the British shores. In the 15th century some very beautiful and noble work, somewhat affected by Flemish influence, was produced in England (fig. 12), chiefly in the form of figures painted on the oak panels of chancel and chapel screens, especially in Norfolk and Suffolk; but, fine as many of these are, they cannot be said to rival in any sense the works of the Van Eycks and other painters of that time in Flanders. To return to the 13th century, the culminating period of English art in painting and sculpture, much was owed to Henry III.'s love for and patronage of the fine arts; he employed a large number of painters to decorate his various castles and palaces, especially the palace of Westminster, one large hall of which was known as the "painted chamber" from the rows of fine pictures with which its walls were covered. After the 13th century the "masonry pattern" was disused for the lower parts of walls, and the chevrony and other stiff

FIG. 12.—15th-century English Painting—St John the Evangelist.

patterns for the borders were replaced by more flowing designs (Plate I.). The character of the painted figures became less monumental in style; greater freedom of drawing and treatment was adopted, and they cease in any way to recall the archaic majesty and grandeur of the Byzantine mosaics. A detailed description of the development of the successive styles of mural painting would be almost a complete history of English art, which space does not allow here, but it may be noted that during the

[1] See *Archæologia*, vol. xlvi., 1880.

14th century wall-spaces unoccupied by figure-subjects were often covered by graceful flowing patterns, drawn with great freedom of hand and rather avoiding geometrical repetition. Fig. 13, from the church of Stanley St Leonard's, Gloucestershire, is a good characteristic specimen of 14th-century decoration; it is on the walls of the chancel, filling up the spaces between the painted figures; the flowers are blue, and the lines red on a white ground. In some cases the motive of the design is taken from encaustic tiles, as at Bengeo Church, Herts, where the wall is divided into squares, each containing an heraldic lion. This imitative notion occurs during all periods—masonry, hanging curtains, tiles, and architectural features such as niches and canopies being very frequently represented, though always in a simple decorative fashion with no attempt at actual deception,—not probably from any fixed principle that shams were wrong, but because the good taste of the mediæval painters taught them that a flat unrealistic treatment gave the best and most decorative effect. Thus in the 15th and 16th centuries the commonest forms of unpictorial wall-decoration were various patterns taken from the beautiful damasks and cut velvets of Sicily, Florence, Genoa, and other places in Italy, some form of the "pine-apple" or rather "artichoke" pattern being the favourite (fig. 14), a design

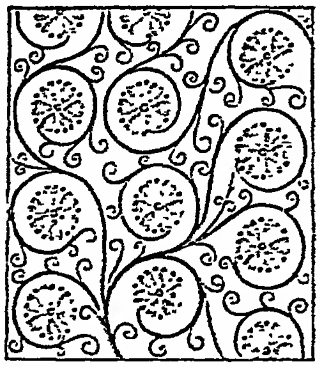

FIG. 13.—Flowing Pattern: English 14th-century Wall-Painting.

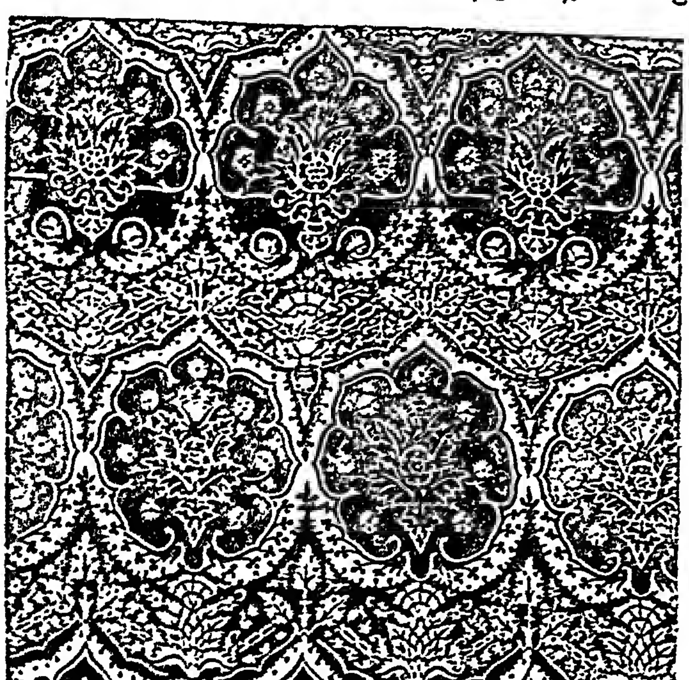

FIG. 14.—15th-century Wall-Painting, taken from a Genoese or Florentine velvet design.

which, developed partly from Oriental sources, and coming to perfection at the end of the 15th century, was copied and reproduced in textiles, printed stuffs, and wall-papers with but little change down to the present century,—a remarkable instance of survival in design. Fig. 15 is a specimen of 15th-century English decorative painting, copied from a 14th-century Sicilian silk damask. Diapers, powderings with flowers, sacred monograms, and sprays of blossom were frequently used to ornament large surfaces in a simple way. Many of these are extremely beautiful (fig. 16).

Subjects of Mediæval Wall-Painting.—In churches and domestic buildings alike the usual subjects represented on the walls were specially selected for their moral and religious teaching, either stories from the Bible and Apocrypha, or from the lives of saints,

FIG. 15.—15th-century Wall-Painting, the design copied from a 13th-century Sicilian silk damask.

or, lastly, symbolical representations setting forth some important theological truth, such as figures of Virtues and Vices, or the *Scala Humanæ Salvationis*, showing the perils and temptations of the human soul in its struggle to escape hell and gain paradise—a rude foreshadowing of the great scheme worked out with such perfection by Dante in his *Commedia*. A fine example of this subject exists on the walls of Chaldon Church, Surrey.[1] In the selection of saints for paintings in England, those of English origin are naturally most frequently represented, and different districts had certain local favourites. St Thomas of Canterbury was one of the most widely popular; but few examples now remain, owing to Henry VIII.'s special dislike to this saint and the strict orders that were issued for all pictures of him to be destroyed. For a similar reason most paintings of saintly popes were obliterated.

FIG. 16.—Powderings used in 15th-century Wall-Painting.

Methods of Execution.—Though Eraclius, who probably wrote before the 10th century, mentions the use of an oil-medium, yet till about the 13th century mural paintings appear to have been executed in the most simple way, in tempera mainly with earth colours applied on dry stucco; even when a smooth stone surface was to be painted a thin coat of whitening or fine *gesso* was laid as a

[1] See *Collections of Surrey Archæol. Soc.*, vol. v. part ii., 1871. A useful though necessarily incomplete list of English mediæval mural paintings has been published by the Science and Art Depart., S. Kens. Mus. Fresh wall-paintings are constantly being discovered under later coats of whitewash, so that any list needs frequent additions.

ground. No instance of true fresco has been discovered in England. In the 13th century, and perhaps earlier, oil was commonly used both as a medium for the pigments and also to make a varnish to cover and fix tempera paintings. Vasari's statement as to the discovery of the use of oil-medium by the Van Eycks is *certainly untrue, but it probably* has a germ of truth. The Van Eycks introduced the use of *dryers* of a better kind than had yet been used, and so largely extended the application of oil-painting. Before their time it seems to have been the custom to dry wall-paintings laboriously by the use of charcoal braziers, if they were in a position where the sun could not shine upon them. This is specially recorded in the valuable series of accounts for the expenses of wall-paintings in the royal palace of Westminster during the reign of Henry III., printed in *Vetusta Monumenta*, vol. vi., 1842. All the materials used, including charcoal to dry the paintings and the wages paid to the artists, are given. The materials mentioned are *plumbum album et rubeum, viridus, vermilio, synople, ocre, azura, aurum, argentum, collis, oleum, vernix.*

Two foreign painters were employed—Peter of Spain and William of Florence—at sixpence a day, but the English painters seem to have done most of the work and received higher pay. William, an English monk in the adjoining Benedictine abbey of Westminster, received two shillings a day. Walter of Durham and various members of the Otho family, royal goldsmiths and moneyers, worked for many years on the adornment of Henry III.'s palace and were well paid for their skill. Some fragments of paintings from the royal chapel of St Stephen are now in the British Museum. They are very delicate and carefully-painted subjects from the Old Testament, in rich colours, each with explanatory inscription underneath. The scale is small, the figures being scarcely a foot high. Their method of execution is curious. First the smooth stone wall was covered with a coat of red, painted in oil, probably to keep back the damp; on that a thin skin of fine gesso (stucco) has been applied, and the outlines of the figures marked with a point; the whole of the background, crowns, borders of dresses, and other ornamental parts have then been modelled and stamped with very minute patterns in slight relief, impressed on the surface of the gesso while it was yet soft. The figures have then been painted, apparently in tempera, gold leaf has been

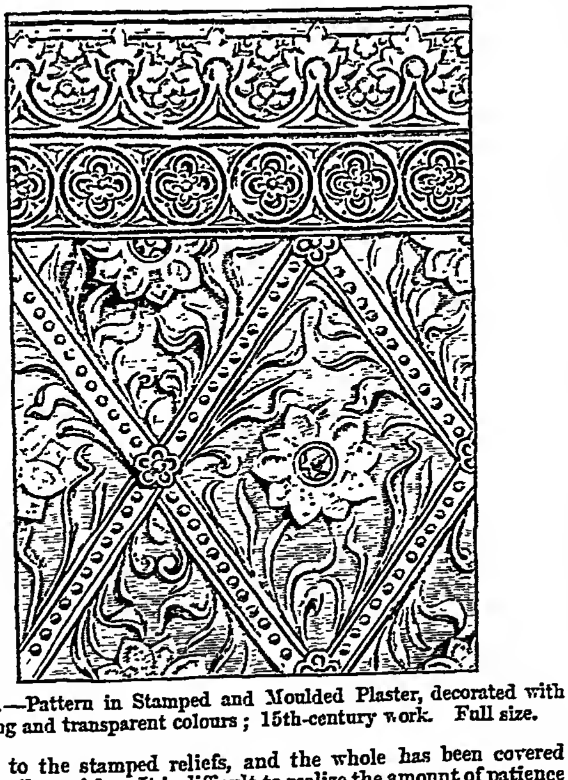

FIG. 17.—Pattern in Stamped and Moulded Plaster, decorated with gilding and transparent colours; 15th-century work. Full size.

applied to the stamped reliefs, and the whole has been covered with an oil varnish. It is difficult to realize the amount of patience and labour required to cover large halls such as the above chapel and the "painted chamber," the latter about 83 feet by 27, with this minute and gorgeous style of decoration.

In many cases the grounds were entirely covered with shining metal leaf, over which the paintings were executed; those parts, such as the draperies, where the metallic lustre was wanted, were painted in oil with transparent colours, while the flesh was painted in opaque tempera. The effect of the bright metal shining through the rich colouring is very magnificent. This extreme minuteness of much of the mediæval wall-decoration is very remarkable. Large wall-surfaces and intricate mouldings were often completely covered by elaborate gesso patterns in relief of almost microscopic delicacy (fig. 17). The cost of stamps for this is among the items in the Westminster accounts. These patterns when set and dry were further adorned with gold and colours in the most laborious way. So also with the architectural painting; the artist was not content simply to pick out the various members of the mouldings in different colours, but he also frequently covered each bead or fillet with painted flowers and other patterns, as delicate as those in an illuminated MS.,—*so minute* and highly-finished that they are almost invisible at a little distance, but yet add greatly to the general richness of effect. All this is completely neglected in modern reproductions of mediæval painting, in which both touch and colour are alike coarse and harsh—mere caricatures of the old work, such as unhappily disfigure the Sainte Chapelle in Paris, and many cathedrals in France, Germany, and England. Gold was never used in large quantities without the ground on which it was laid being broken up by some such delicate reliefs as that shown in fig. 17, so its effect was never gaudy or dazzling.

Mural painting in England fell into disuse in the 16th century. For domestic purposes wood panelling, stamped leather, and tapestry were chiefly used as wall-coverings. In the reign of Henry VIII., probably in part through Holbein's influence, a rather coarse sort of tempera wall-painting, German in style, appears to have been common.[1]

A good example of arabesque painting of this period in black and white, rudely though boldly drawn and very Holbeinesque in character, was discovered in 1881 behind the panelling in one of the canons' houses at Westminster. Other examples exist at Haddon Hall (Derbyshire) and elsewhere.

Several attempts have been made in the present century to revive the art of monumental wall-decoration, but mostly, like those in the new Houses of Parliament, unsuccessful both in method and design. A large wall-painting by Sir Frederick Leighton of the Arts of War, on a wall in the South Kensington Museum, is much disfigured by the disagreeable gravelly surface of the stucco. The process employed is that invented by Mr Gambier Parry, and called by him "spirit fresco." A very fine series of mural paintings has been executed by Mr Madox Brown on the walls of the Manchester town-hall. These also are painted in Mr Parry's "spirit fresco," but on a smooth stucco surface, free from the unpleasant granular appearance of the South Kensington picture.

The Mediæval Wall-Paintings of the Continent.—In the main the above remarks on English mural decoration apply equally to that of France, Germany, and Scandinavia. Though each of these countries had certain peculiarities of style, mostly slight and unimportant, yet in method of execution, choice and arrangement of subjects, and division of the wall-spaces there is a very close similarity between them all. Italy, on the other hand, developed a style of her own, more purely pictorial, with less regard to the exigencies of architecture. In northern lands the mural paintings were strictly subordinate to the main features of the structure for which they were designed, while in Italy as a rule the architect did but little to decorate the interior of his buildings, and left the painter free to treat the walls as he pleased.

The very close similarity of the mural decoration in the churches of Sweden to those of England is very remarkable, and some of the Swedish churches have very magnificent and well-preserved schemes of decoration, covering walls and ceilings alike, of dates varying from the 13th to the 15th centuries, all of which have little or nothing to distinguish them from contemporary work in England. Mandelgren's *Monuments Scandinaves* (1862) has well-executed reproductions of some of the best of these, especially the fine and complete specimens in the churches of Bjeresjoe,

[1] Shakespeare, *Henry IV.*, part ii., act 2, sc. 1: "*Falstaff.* And for thy walls, a pretty slight drollery, or the story of the prodigal, or the German hunting in *waterwork*, is worth a thousand of these bed-hangings and these fly-bitten tapestries"

Ameneharads Räda, Risingë, and Floda. One of these, the north chancel wall of the church of Räda, 13th century, has been selected (Plate I.) as a good and characteristic example of the treatment of a large wall-space in the 14th century; the dado of painted curtain-folds, the tiers of single life-size figures in architectural niches treated with great breadth and decorative skill, and the band below of subjects on a rather smaller scale give a good idea of a common scheme of ecclesiastic decoration. An inscription on one of these paintings gives the date of their execution as 1323. The lower subject represents the death of the Virgin, above are figures of the apostles, and highest of all, painted on the curved boarding of the waggon-vault, are a row of seated prophets under round arches. The other examples on the same plate, given as specimens of 15th-century flowing patterns, are from the church of Kumbla, also in Sweden, and fully illustrated in Mandelgren's valuable work.

Oriental Painting.—In the churches and monasteries of the Greeks mural painting is still practised very much as it was in the 12th or 13th centuries.[1] Neither colouring, nor drawing, nor method has in the least altered during the last six hundred years. Everything is fixed by certain unchangeable hieratic rules, and the Greek painter-monk would think it impious to improve upon or deviate from the artistic canons for sacred subjects handed down from century to century. For this reason it is generally impossible, from internal evidence, to guess the date of the interesting wall-paintings with which many churches in eastern Europe, Egypt, and Asia Minor are decorated.

In India and Ceylon mural painting has been largely used from very early times, especially to decorate the walls of temples. Some of these appear to be executed in true fresco. Birth-stories of Buddha and other sacred subjects most frequently occur. As among the mediæval and modern Greeks, the strong conservatism of the Hindu races makes it difficult to judge as to the dates of these paintings.[2] (W. MO.—J. H. M.)

MURANO, the ancient Ammariuno, an island in the Venetian lagoon about 1 mile north of Venice, is 5 miles in circumference, a large part of which is occupied by gardens. It contains about 4000 inhabitants, but was once much more populous than it is at present, its inhabitants numbering 30,000. It was a favourite resort of the Venetian nobility before they began to build their villas on the mainland; and in the 15th and 16th centuries its gardens and casinos, of which some traces still remain, were famous. It was here that the literary clubs of the Vigilanti, the Studiosi, the Occulti, used to meet.

The town is built upon one broad main canal, where the tidal current runs with great force, and upon several smaller ones. The cathedral, S. Donato, is a fine basilica, probably of the 11th century. The pavement is as richly inlaid as that of St Mark's, and the mosaics of the tribune are remarkable. The exterior of the tribune is very beautiful, and has been successfully restored. The 15th-century church of St Peter the Martyr contains a fine picture by Gentile Bellini. Murano has from ancient times been celebrated for its glass manufactories. When and how the art was introduced is wrapped in great obscurity, but there are notices of it as early as the 11th century; and in 1250 Cristoforo Briani, encouraged by the accounts of the gems of Guinea which the traveller Marco Polo brought to Venice, attempted the imitation of agate and chalcedony. From the labours of his pupil Miotto sprang the whole of that branch of the glass trade which is concerned with the imitation of gems. In the 15th century the first crystals were made, and in the 17th the various gradations of coloured and iridescent glass were invented, together with the composition called "aventurine"; the manufacture of beads is now a main branch of the trade. The art of the glass-workers was taken under the protection of the Government in 1275, and regulated by a special code of laws and privileges; two fairs were held annually, and the export of all materials, such as alum and sand, which enter into the composition of glass was absolutely forbidden. With the decay of Venice the importance of the Murano glass-works declined; but at the present time there are signs of renewed activity. As many as eight firms, employing 2500 hands, are engaged in the trade,—the most renowned being "The Venezia Murano Company" and Salviati. The municipal museum contains a collection of glass illustrating the history and progress of the art.

The island of Murano was first peopled by the inhabitants of Altino, when they fled before their barbarian invaders. It originally enjoyed independence under the rule of its tribunes and judges, and was one of the twelve confederate islands of the lagoons. In the 12th century the doge Vital Micheli II. incorporated Murano in Venice and attached it to the Sestiere of S. Croce. From that date it was governed by a Venetian nobleman with the title of podestà, whose office lasted sixteen months. Murano, however, still retained its original constitution of a greater and a lesser council for the transaction of municipal business, and also the right to coin gold and silver, as well as its judicial powers civil and criminal. The interests of the town were watched at the ducal palace by a nuncio and a solicitor; and this constitution remained in force till the fall of the republic.

MURAT, JOACHIM (1768-1815), king of Naples and a celebrated French cavalry leader, was, according to most accounts, the younger son of an innkeeper at Bastide Fortunière in the department of Lot, France, and was born in 1768, but by his own account his father was a well-to-do farmer in that village. This is most probably the truth, as after being educated at a seminary at Cahors he was entered at the university of Toulouse, where he studied canon law. He was intended for the priesthood, but led a reckless life; and after spending all his money he enlisted in a cavalry regiment. He had attained the rank of "maréchal des logis" in 1789, and was the recognized leader of the young soldiers from his great prowess in all athletics and feats of daring. His influence was so great and so prejudicial to authority that he received unlimited leave of absence in 1790. In November 1791 he was elected by the department of Lot a member of the garde

constitutionelle of the king. In May 1792 the garde was disbanded, but Murat had shown such military qualities and such advanced principles that he was at once appointed a sub-lieutenant in the chasseurs-à-cheval, and on the outbreak of war aide-de-camp to General Hué. He was rapidly promoted to be captain and major in the 21st chasseurs, but after Thermidor found himself looked upon with suspicion on account of his former advanced republican sentiments. He was recalled from the front, and happened to be wandering about Paris in the spring and summer of 1795, like another unemployed officer, Napoleon Bonaparte, whose acquaintance he made, and whose friendship he won. When Bonaparte was requested by Barras to undertake the defence of the convention in Vendémiaire 1795 he at once called Murat to his side and commissioned him to bring up from Sèvres the artillery with which the sections were shot down. His services on this occasion were recognized by his receiving the lieutenant-colonelcy of the 21st chasseurs and the appointment of first aide-de-camp to General Bonaparte in Italy. In the first battles of the famous campaign of 1796, Montenotte, Ceva, Dego, and Mondovi, Murat so greatly distinguished himself that he was chosen to carry the flags taken from the enemy to Paris. He was promoted to be general of brigade, and returned to Italy in time to be of essential service to Bonaparte at Bassano and Corona and Fort St Georges, where he was wounded. He then was sent on a diplomatic mission to Genoa, but returned in time to be present at Rivoli. In the advance into Tyrol in the summer of 1797 he commanded the vanguard, and by his passage of the Tagliamento hurried on the preliminaries of Leoben. In 1798 he was for a short time commandant at Rome, and then accompanied Bonaparte to Egypt. At the battle of the Pyramids he led his first famous cavalry charge, and so distinguished himself in Syria that he was made general of division. He returned to France with Bonaparte, and on the 18th Brumaire led into the orangery of Saint Cloud the sixty grenadiers whose appearance broke up the Council of Five Hundred. He was, after the success of the coup d'état, made commandant of the consular guard, and in January 1800 married Marie Annonciade Caroline Bonaparte, the youngest sister of the first consul. He commanded the French cavalry at the battle of Marengo, and was afterwards made governor in the Cisalpine Republic. He was made a marshal of France in 1804; he was titular governor of Paris, was invested with the grand eagle of the Legion of Honour, and appointed grand admiral of France with the title of prince in 1805. He commanded the cavalry of the grand army in the German campaign of 1805, and was so conspicuous at Austerlitz that Napoleon made him grand-duke of Berg and Cleves. He commanded the cavalry at Jena, Eylau, and Friedland, and in 1808 was made general-in-chief of the French armies in Spain. He entered Madrid on 25th March, and did much to hurry on the Spanish policy of Napoleon. The inhabitants of Madrid showed their hatred for the French by murdering on 2d May all the isolated or wounded Frenchmen they could find. Murat vigorously put down the riot, but not cruelly, for only 158 Spaniards fell to 500 Frenchmen; and he hoped for the throne of Spain as his reward. But the throne of Spain was given to Joseph Bonaparte, and Murat received Joseph's former kingdom of Naples.

King Joachim Napoleon, as he called himself, entered Naples in September 1808, and soon won great popularity by his handsome presence and his gaiety of manner. He took Capri from the English, and organized a Neapolitan army of 80,000 infantry and 10,000 cavalry. But his attention was not confined to military matters; he effected other great reforms in finally abolishing all relics of feudalism and putting down brigandism. Unfortunately much injustice was done by General Manhès in this last reform, which seriously affected Murat's popularity in Calabria. He was not present at Aspern or Wagram, but once more commanded the cavalry of the grand army in the Russian campaign of 1812. He manifested his usual headlong valour in the disastrous retreat, but, being offended by Napoleon, he suddenly threw up his command and left for Naples. He then began an intrigue with Austria. Whether it was that he hoped to escape from a doubtful cause or that he was really offended by Napoleon's preference for Eugène Beauharnais is not known, but in March 1813 he sent Prince Cariati to Vienna to declare that he would surrender his claims to Sicily if Austria would guarantee Naples to him. In January 1814 the alliance with Austria was declared by Murat's seizing the principality of Benevento, while Austria promised him Ancona for a force of 30,000 men. At the congress of Vienna his independence was attacked by Talleyrand, who was his personal enemy, and it was as much from distrust of Austria as anything else that he declared in March 1815 that he intended to restore the unity and independence of Italy. He had hoped that Lord William Bentinck, the English general, would have supported him, but in vain. The Austrians steadily advanced, and on 2d May he suffered a disastrous defeat at the battle of Tolentino. With difficulty he escaped, and reached France on 27th May. He offered his sword to Napoleon, who indignantly refused his offer, and he then hid in seclusion near Toulon with a price upon his head. After Waterloo he was refused an asylum in England, and went to Corsica, where he was joined by a few rash spirits, who urged him to strike another blow for his kingdom of Naples. He refused an offer of asylum from Metternich, and started with six ships. By a great mistake he landed in Calabria, where he was hated for the cruelty of Manhès, on 6th October; his ships deserted him, and he was taken prisoner by a captain named Trenta-Capilli, whose brother had been executed by Manhès. He was imprisoned in the fort of Pizzo, and on 13th October 1815 was tried by court-martial, under a law of his own, for disturbing the public peace and was sentenced to be shot in half an hour. After writing a touching letter of farewell to his wife and children, he bravely met his fate, and was buried at Pizzo.

As a king much good can be said of him; by his valour he had risen from nothing to royalty, and instead of being careless of the good of his adopted country he showed himself a truly wise king. As a general he was the most dashing cavalry leader of the age, and, as he himself said, his presence at Waterloo would have given more concentrated power to the French cavalry charges, and possibly success. As a man he was rash, hot-tempered, and impetuously brave; he was adored by his troopers, who followed their idol, the "golden eagle," into the most terrible fire and against the most terrible odds.

MURATORI, LUDOVICO ANTONIO (1672-1750), a learned Italian scholar, historian, and antiquary, was born at Vignola in the duchy of Modena 21st October 1672. Whilst still young he attracted the attention of Father Bacchini,

the librarian of the duke of Modena, by whom he was inspired with a taste for historical and antiquarian research, and introduced to the study of MSS. Having taken minor orders in 1688, Muratori proceeded to his degree of doctor *in utroque jure* before 1694, in which year he was appointed by Count Carlo Borromeo one of the doctors of the Ambrosian library at Milan. From manuscripts now placed under his charge, and which had been hitherto neglected, he made a selection of materials for several volumes (*Anecdota*), which he published with critical and explanatory notes. The reputation he in consequence acquired was such that the duke of Modena offered him the situation of keeper of the public archives of the duchy. Muratori hesitated, until the offer of the additional post of librarian, on the resignation of Father Bacchini, determined him in 1700 to return to Modena. The remainder of his life was an almost uninterrupted course of ardent and indefatigable intellectual labour. The preparation of numerous valuable tracts on the history of Italy during the Middle Ages, and of dissertations and discussions on obscure points of historical and antiquarian interest, as well as the publication of his various philosophical, theological, legal, poetical, and other works absorbed the greater part of his time and attention. These as they successively appeared added to his growing reputation, and brought him into communication with the most distinguished scholars of Italy, France, and Germany. But they also exposed him in his later years to the machinations of the envious. His enemies spread abroad the rumour that the pope, Benedict XIV., had discovered in his writings passages strongly savouring of heresy, even of atheism. Muratori appealed to the pope, repudiating the accusation. His Holiness assured him of his protection, and, without expressing his approbation of the opinions in question of the learned antiquary, freed him from the imputations of his enemies. Muratori died, after a lengthened illness, on 23d January 1750, and was buried with much pomp in the church of Santa Maria di Pomposa, in connexion with which he had laboured as a diligent parish priest for many years. His remains were afterwards, in the year 1774, removed to the church of St Augustin.

The most important of the works of Muratori, which amounted altogether to upwards of sixty-four, are: *Anecdota ex Ambrosianæ Bibliothecæ Codd.*, Milan, 1697, 1698; Padua, 1713, 2 vols. 4to; *Anecdota Græca*, Padua, 1709, 3 vols. 4to; *Antichità Estensi*, Modena, 1717, 2 vols. folio; *Rerum Italicarum Scriptores præcipui ab anno 500 ad 1500*, Milan, 1723-1751, 25 vols. folio; *Antiquitates Italicæ medii ævi*, Milan, 1738-1742, 6 vols. folio; *Novus Thesaurus Veterum Inscriptionum*, Milan, 1739-1742, 6 vols. folio; *Annali d'Italia*, Venice, 1744-1749, 12 vols. 4to. His *Letters*, with a *Life prefixed*, were published by Lazzari, in 1783, Venice, 2 vols. His nephew, G. F. Muratori, also wrote a *Vita del celebre Ludov. Ant. Muratori*, Venice, 1756. Muratori's Latin and Italian works were published at Arezzo, 1767-1780, 36 vols. 4to. See further Tiraboschi, *Biblioteca Modenese*, vols. iii., iv.; Fabroni, *Vitæ Italorum*, vol. x.; Tipaldo, *Biogr. degli Italiani illustri*, vol. vii.

MURCHISON, Sir Roderick Impey (1792-1871), geologist, was descended from a small clan or sept which for many generations lived in the west of Ross-shire, furnishing factors for some of the greater lairds, occupants of farms among the western sea-lochs, and even occasionally a parish minister. His father, educated as a medical man, acquired a competent fortune in India, and while still in the prime of life returned to Scotland, where, marrying one of the Mackenzies of Fairburn, he purchased the estate of Tarradale in eastern Ross and settled for a few years as a resident Highland landlord. At Tarradale his eldest son, the subject of this notice, was born on 19th February 1792. Young Murchison left the Highlands when only three years old, and at the age of seven was sent to the grammar school of Durham, where during six years he received the only connected general education he ever obtained. He was then placed at the military college, Great Marlow, to be trained for the army. With some difficulty he succeeded in passing the not very stringent examinations of the time, and at the age of fifteen was gazetted ensign in the 36th regiment. A year later (1808) he landed with Wellesley in Galicia, and was present at the actions of Roriça and Vimiera. Subsequently under Sir John Moore he took part in the retreat to Corunna and the final battle there. These six months of active service formed the only part of his military career in which he was exposed to the hardships and dangers of actual warfare. The defeat of Napoleon at Waterloo seeming to close the prospect of advancement in the military profession, Murchison, after eight years of service, quitted the army, and married the daughter of General Hugonin, of Nursted House, Hampshire. With her he then spent rather more than two years on the Continent, particularly in Italy, where her cultivated tastes were of signal influence in guiding his pursuits. He threw himself with all the enthusiasm of his character into the study of art and antiquities, and for the first time in his life tasted the pleasures of truly intellectual pursuits.

Returning to England in 1818, he sold his paternal property in Ross-shire and settled in England, where, finding art studies no longer practicable, he took heart and soul to field-sports. He soon became one of the greatest fox-hunters in the northern counties; but at last, getting weary of such pursuits and meeting Sir Humphrey Davy, who urged him to turn his energy to science, he was induced to attend lectures at the Royal Institution. This change in the current of his occupations was much helped by the sympathy of his wife, who, besides her artistic acquirements, took much interest in some branches of natural history. Eager and enthusiastic in whatever he undertook, he was soon fascinated by the young science of geology, and threw himself heartily into its prosecution. He joined the Geological Society of London and soon showed himself one of its most active members, having as his colleagues there such men as Sedgwick, Lyell, Buckland, Herschel, Whewell, and Babbage. Exploring with his wife the geology of the south of England, he devoted special attention to the rocks of the north-west of Sussex and the adjoining parts of Hants and Surrey, on which he wrote his first scientific paper, read to the Society towards the close of 1825. From that early period on to the end of his long life his industry and enthusiasm remained pre-eminent. Though he had reached the age of thirty-two before he took any interest in science, he developed his taste and increased his knowledge so rapidly by unwearied diligence that in the first three years of his scientific career he had explored large parts of England and Scotland, had obtained materials for three important memoirs, as well as for two more written in conjunction with Sedgwick, and from the position of a mere beginner had risen to be a prominent member of the Geological Society and one of its two secretaries.

Turning his attention for a little to Continental geology, he explored with Lyell the volcanic region of Auvergne, parts of southern France, northern Italy, Tyrol, and Switzerland. A little later, with Sedgwick as his companion, he attacked the difficult problem of the geological structure of the Alps, and their joint paper giving the results of their study will always be regarded as one of the classics in the literature of Alpine geology.

It was in the year 1831 that Murchison found the field in which the chief work of his life was to be accomplished. Acting on a suggestion made to him by Buckland he betook himself to the borders of Wales, with the view of endeavouring to discover whether the greywacke rocks underlying the Old Red Sandstone could be grouped

into a definite order of succession, as the Secondary rocks of England had been made to tell their story by William Smith. For several years he continued to work vigorously in that region. The result was the establishment of the Silurian system,—a definite section of the geological record, bringing into notice for the first time a remarkable series of formations, each replete with distinctive organic remains older than and very different from those of the other rocks of England. The full import of his discoveries[1] was not at first perceived; but as years passed on the types of existence brought to light by him from the rocks of the border counties of England and Wales were ascertained to belong to a geological period of which there are recognizable traces in almost all parts of the globe. Thus the term "Silurian," derived from the name of the old British tribe Silures, soon passed into the familiar vocabulary of geologists in every country.

The establishment of the Silurian system was followed by that of the Devonian system, an investigation in which Sedgwick and Murchison were fellow-labourers, both in the south-west of England and in the Rhinelands. Soon afterwards Murchison projected an important geological campaign in Russia with the view of extending to that part of the Continent the classification he had succeeded in elaborating for the older rocks of western Europe. He was accompanied by De Verneuil and Keyserling, in conjunction with whom he produced a magnificent work on *Russia and the Ural Mountains*. The publication of this monograph in 1845 completes the first and most active half of Murchison's scientific career.

In 1846 he was knighted, and later in the same year he presided over the meeting of the British Association at Southampton. During the later years of his life a large part of his time was devoted to the affairs of the Royal Geographical Society, of which he became president. So constant and active were his exertions on behalf of geographical exploration that to a large section of the contemporary public he was known rather as a geographer than as a geologist. He particularly identified himself with the fortunes of David Livingstone in Africa, and did much to raise and keep alive the sympathy of his fellow-countrymen in the fate of that great explorer. The chief geological investigation of the last decade of his life was devoted to the Highlands of Scotland, where he succeeded in showing that the vast masses of crystalline schists, previously supposed to be part of what used to be termed the Primitive formations, were really not older than the Silurian period, for that underneath them lay beds of limestone and quartzite containing Lower Silurian fossils. By this important discovery he not only changed at once the accepted views of the structure of half a kingdom but furnished a gigantic example of regional metamorphism, the true significance of which in regard to theories of metamorphism is not yet adequately appreciated.

In the year 1855 Murchison was appointed director-general of the geological survey and director of the Royal School of Mines and Geological Museum, Jermyn Street, London, in succession to Sir Henry de la Beche, who had been the first to hold these offices. Official routine now occupied much of his time, but he found opportunity for the Highland researches just alluded to, and also for preparing successive editions of his work *Siluria*, which was meant to present the main features of the original *Silurian System* together with a digest of subsequent discoveries, particularly of those which showed the extension of the Silurian classification into other countries. His official position gave him still further opportunity for the exercise of those social functions for which he had always been distinguished, and which a considerable fortune inherited from near relatives on his mother's side enabled him to display on a greater scale. His house was one of the great centres where science, art, literature, politics, and social eminence were brought together in friendly intercourse. In 1863 he was made a K.C.B., and three years later was raised to the dignity of a baronet. The learned societies of his own country bestowed their highest rewards upon him: the Royal Society gave him the Copley medal, the Geological Society its Wollaston medal, and the Royal Society of Edinburgh its Brisbane medal. There was hardly a foreign scientific society of note which had not his name enrolled among its honorary members. The French Academy of Sciences awarded to him the Prix Cuvier, and elected him one of its eight foreign members in succession to Faraday.

One of the closing public acts of Murchison's life was the founding of a chair of geology and mineralogy in the university of Edinburgh, for which he gave the sum of £6000, an annual sum of £200 being likewise provided by a vote in parliament for the endowment of the professorship. While the negotiations with the Government in regard to this subject were still in progress, Murchison was seized with a paralytic affection on 21st November 1870. At first his life was in danger, but he eventually rallied, and was able to see his friends, read, and take interest in current affairs until the early autumn of the following year, when his malady began to make rapid progress. At last after a brief attack of bronchitis he died on 22d October 1871.

The chief work for which Murchison will always hold a high place in the annals of geology is the investigation of the older Palæozoic rocks, which culminated in the establishment and subsequent development of the Silurian system of formations. He added a new chapter to geological history, and one of peculiar interest because it contains the story of almost the earliest appearance of living things upon this planet. From the year 1825, when his first paper was read, down to the year of his death he continued to augment the literature of his favourite science with papers and memoirs. These, upwards of 150 in number, were published in the transactions of scientific societies at home and abroad. His *Silurian System*, *Russia and the Ural Mountains*, and *Siluria* were the most voluminous and important of his independent works. As a careful original observer, a sympathetic and liberal friend of scientific progress, and a man of wealth and good social position Murchison enjoyed a peculiar eminence among the scientific men of his day, and occupied a place which none of his surviving compeers could wholly fill. See Murchison's *Life* by A. Geikie, 1875. (A. GE.)

MURCIA, a maritime province of south-eastern Spain, is bounded on the E. and S. by Alicante and the Mediterranean, on the W. by Almeria and Granada, and on the N. by Albacete, and has an area of 4478 square miles. The total extent of coast is about 75 miles; from Cape Palos westwards to Villaricos Point (where Almeria begins) it is fringed by hills reaching their greatest elevation immediately to the east of Cartagena; northwards from Cape Palos to the Alicante boundary a low and sandy tongue of land encloses the shallow lagoon called Mar Menor. Eastward from the Mar Menor and northward from Cartagena stretches the plain known as El Campo de Cartagena, but the surface of the rest of the province is diversified by ranges of hills of which the general direction, connecting the mountains of Almeria and Granada with those of Alicante, is from south-west to north-east, and which reach their highest point (5150 feet) on the Sierra de España, between the Mula and Sangonera valleys. They belong to the Nevada system, and their geology will be best treated in connexion with that of Spain generally; they are rich in iron, copper, and argentiferous lead, and also yield large quantities of alum, sulphur, and saltpetre; and important mineral springs occur at Mula, Archena (hot sulphur), and Alhama (hot chalybeate).

[1] The results of these researches were embodied in a massive quarto volume entitled *The Silurian System* (London, 1839).

The greater part of the province drains into the Mediterranean, chiefly by the Segura, which enters it in the north-west below Hellin in Albacete, and leaves it a little above Orihuela in Alicante; within the province it receives on the left the Arroyo del Jua, and on the right the Caravaca, Quipar, Mula, and Sangonera. The insignificant "arroyos" of Nogalte and Albujon fall directly into the Mediterranean and the Mar Menor respectively. The climate is hot and dry, and agriculture is largely dependent on irrigation, which, where practicable, has been carried on since the time of the Moors with great success. Besides the usual cereals (wheat, barley, maize), hemp, oil, and wine (the latter somewhat rough in quality) are produced; fruit, especially the orange, is abundant along the course of the Segura; mulberries for sericulture are extensively grown around the capital; and the number of bees kept throughout the province is exceptionally large. Esparto grass is gathered on the sandy tracts suited to its growth. The live stock consists chiefly of asses, mules, goats, and pigs, horses and sheep being relatively few. Apart from agriculture, the principal industry is that of mining, which has its centre near Cartagena; next comes the culture of the silkworm, the greater part of the crop being exported for manufacture in France. Large quantities of lead and esparto, as well as of zinc, iron, and copper ores and sulphur, are exported from Cartagena; from Águilas the chief exports are esparto and agricultural produce; the port of Mazarron has some trade in alum as well. The province is traversed by a railway line which connects Albacete with Cieza, Archena, Murcia, Orihuela, and Cartagena; the capital is also connected with Lorca and Alicante by good high roads. The communications otherwise are somewhat defective. The canal to connect Huescar in Granada with Cartagena remains only a project. The population of the province in 1877 was 451,611. Besides the cities of Murcia, Cartagena, and Lorca, the following towns in that year had a population exceeding 5000:—Abanilla, Águilas, Alhama, Bullas, Caravaca, Cehegin, Cieza, Fortuna, Fuente-Álamo, Jumilla, Mazarron, Molina, Moratalla, Mula, Torre-Pacheco, Totana, La Union, Yecla.

The province of Murcia was the first Spanish possession of the Carthaginians, by whom Nova Carthago was founded. The Romans included it in Hispania Tarraconensis. Under the Arabs the province was known as Todmír, which included, according to Edrisi, the cities Murcia, Orihuela, Cartagena, Lorca, Mula, and Chinchilla. The kingdom of Murcia, which came into independent existence after the fall of the Omayyads, included the present Albacete as well as Murcia. It became subject to the crown of Castile in the 13th century. Until 1833 the modern province also included Albacete.

MURCIA, a city of Spain, capital of the above province, stands on the Segura, nearly in the centre of the beautiful and fertile valley known as the "huerta" or garden of Murcia, which is sheltered on the south by the eastward continuation of the Sierras Alcaraz and Segura, and on the north by the low hills of the Sierras de Molina. The main part of the town stands on the left bank of the river, and is connected with the suburb of San Benito on the right by a very fine stone bridge of two arches. The streets are mostly broad, straight, and well paved; the chief shops are in the narrow Calles de Plateria and Traperia, which are also a favourite resort with loungers, being shaded with awnings of canvas in hot weather. The chief square is the Plaza de la Constitucion, which is planted with orange and other trees; other promenades are the Paseos del Carmen and de Florida Blanca. Of public buildings the most prominent is the cathedral, a late Gothic (1388-1467) structure with a Corinthian façade in the taste of the 17th century; the tower is also composite, having been begun in 1521 and completed in 1766. Murcia has been the seat of the bishop of Cartagena since 1261; the present palace was erected in 1748-52. Near it are the colleges of San Fulgencio and San Isidoro. Other conspicuous public buildings are the hospital of San Juan de Dios, the silk and saltpetre factories, and the "alhondiga" or grain warehouse. The bull-ring is in San Benito. The manufactures of the town are not important; the chief articles of commerce are the silk grown on the huerta, fruit, and agricultural produce. The population in 1877 was 91,805.

Murcia has been identified by some with the Roman *Vergilia*. In the time of Edrisi it was the populous and strongly-fortified capital of the country of Todmír. It was taken in 1240 by Don Alfonso (afterwards King Alfonso el Sabio), who by his own request lies buried here. The town was plundered by General Sebastiani, and in 1810 and again in 1812 suffered from the attack of a detachment of Soult's army. In 1829 an earthquake caused considerable injury, especially to the cathedral.

MURDER, MANSLAUGHTER. In the law of England the unlawful killing of a human being is either murder or manslaughter according as it is or is not accompanied by circumstances constituting the element of malice aforethought. That, according to the old definition of Coke, is the criterion by which murder is distinguished from manslaughter.[1] In like manner Blackstone lays it down as a "general rule" that all homicide is in the eye of the law malicious, and therefore murder, unless it is either *justified* by the command or permission of the law, *excused* on account of accident or self-preservation, or *alleviated* into manslaughter by being the involuntary consequence of some act not strictly lawful, or occasioned by some sudden and sufficiently violent provocation. An exact account of these related offences can only be obtained by an examination of a vast number of judicial decisions, most of which are to be found in the ordinary text-books. (See, more particularly, Russell *On Crimes and Misdemeanours.*) The task of evolving exact definitions from this mass of material has been successfully undertaken by Mr Justice Stephen, and we cannot do better than present here the conclusions at which he has arrived. Art. 223 of his *Digest of the Criminal Law* is as follows:—"Manslaughter is unlawful homicide without malice aforethought. Murder is unlawful homicide with malice aforethought. Malice aforethought means any one or more of the following states of mind preceding or coexisting with the act or omission by which death is caused, and it may exist when that act is unpremeditated:—(*a*) an intention to cause the death of, or grievous bodily harm to, any person, whether such person is the person actually killed or not; (*b*) knowledge that the act which causes death will probably cause the death of, or grievous bodily harm to, some person, whether such person is the person actually killed or not, although such knowledge is accompanied by indifference whether death or grievous bodily harm is caused or not, or by a wish that it may not be caused; (*c*) an intent to commit any felony whatever; (*d*) an intent to oppose by force any officer of justice on his way to, on, or returning from the execution of the duty of arresting, keeping in custody, or imprisoning any person whom he is lawfully entitled to arrest, keep in custody, or imprison, or the duty of keeping the peace or dispersing an unlawful assembly, provided that the offender has notice that the person killed is such an officer so employed." The expression "officer of justice" in this clause includes every person who has a legal right to do any of the acts mentioned, whether he is an officer or a private person. Notice may be given either by word, by the production of a warrant or other legal authority, by the known official character of the person killed, or by the circumstances of the case. Art. 224 states that "homicide which would

[1] "When a person of sound memory and discretion unlawfully killeth any reasonable creature in being and under the king's peace with malice aforethought either express or implied" (Coke, 3 *Inst.*).

otherwise be murder is not murder but manslaughter if the act by which death is caused is done in the heat of passion, caused by provocation," the acts amounting to which are enumerated. But provocation does not extenuate the offence "unless the person provoked is at the time when he does the act deprived of the power of self-control by the provocation which he has received, and in deciding the question whether this was or was not the case regard must be had to the nature of the act by which the offender caused death, to the time which elapsed between the provocation and the act which caused death, to the offender's conduct during that interval, and to all other circumstances tending to show the state of his mind."

The law of the future is almost certainly to be found in the draft code presented by the Criminal Code Bill Commissioners of 1879, and founded on Mr Justice Stephen's *Digest* above cited. The enactment of this measure being a mere question of time some of its provisions may usefully be stated here.

After defining homicide and culpable homicide, the code (sect. 74) declares culpable homicide to be murder in the following cases:—(*a*) if the offender means to cause the death of the person killed; (*b*) if the offender means to cause to the person killed any bodily injury which is known to the offender to be likely to cause death, and if the offender, whether he does or does not mean to cause death, is reckless whether death ensues or not; (*c*) if the offender means to cause death or such bodily injury as aforesaid to one person, so that if that person be killed the offender would be guilty of murder, and by accident or mistake the offender kills another person though he does not mean to hurt the person killed; (*d*) if the offender for any unlawful object does an act which he knows or ought to have known to be likely to cause death, and thereby kills any person, though he may have desired that his object should be effected without hurting any one.

Further (sect. 75), it is murder (whether the offender means or not death to ensue, or knows or not that death is likely to ensue) in the following cases:—"(*a*) if he means to inflict grievous bodily injury for the purpose of facilitating the commission of any of the offences hereinafter mentioned, or the flight of the offender upon the commission or attempted commission thereof, and death ensues from his violence; (*b*) if he administers any stupefying thing for either of the purposes aforesaid and death ensues from the effects thereof; (*c*) if he by any means wilfully stops the breath of any person for either of the purposes aforesaid and death ensues from such stopping of the breath." The following are the offences referred to:—"high treason and other offences against the queen's authority, piracy and offences deemed to be piracy, escape or rescue from prison or lawful custody, resisting lawful apprehension, murder, rape, forcible abduction, robbery, burglary, arson." The code (sect. 76) reduces culpable homicide to manslaughter if the person who causes death does so "in the heat of passion caused by sudden provocation;" and "any *wrongful act or insult* of such a nature as to be sufficient to deprive any ordinary person of the power of self-control may be provocation if the offender acts upon it on the sudden, and before there has been time for his passion to cool." Whether any particular wrongful act or insult amounts to provocation and whether the offender was deprived of self-control shall be questions of fact; but no one shall be deemed to give provocation by doing that which he had a legal right to do, or which the offender incited him to do in order to provide an excuse for killing him or doing grievous bodily harm. Further, "an arrest shall not necessarily reduce the offence from murder to manslaughter because an arrest was illegal, but if the illegality was known to the offender it may be evidence of provocation." The "provocation" clause is not very happily expressed and will doubtless have to be recast.

America.—The most notable difference between England and the United States in regard to the law on this subject is the recognition by recent State legislation of degrees in murder. English law treats all unlawful killing not reducible to manslaughter as of the same degree of guilt. American statutes seek to discriminate between the graver and the less serious forms of the crime. Thus an Act of the legislature of Pennsylvania (22d April 1794) declares all murder which shall be perpetrated by means of poison or by lying in wait or by any other kind of wilful, deliberate, and premeditated killing, or which shall be committed in the perpetration of or attempt to perpetrate any arson, rape, robbery, or burglary shall be deemed murder of the first degree; and all other kinds of murder shall be deemed murder of the second degree. This statute, says Bishop (*Commentaries on the Criminal Law*, vol. ii. § 745), "is the parent of all the others." In Michigan it has been enacted in exact words; and in most of the other States which have adopted this line of legislation the departure from the language of the Pennsylvania provision is not such as calls for the application of different principles of interpretation. It is pointed out by Bishop that the language used in these statutes to discriminate the degrees of murder is similar to that by which the common law distinction between murder and manslaughter is usually expressed. Thus in Massachusetts murder committed with "deliberately premeditated malice aforethought" is in the first degree. In Indiana the expression used is "purposely and of deliberate and premeditated malice." The technical interpretation of "malice aforethought" in English law is of course inapplicable to these phrases. There are also statutory degrees of manslaughter in the legislation of some of the States, but Bishop observes that "the books do not contain sufficient adjudications to direct us into a profitable discussion of this subject."

For some historical account of the law reference should be made to Mr Justice Stephen's *History of the Criminal Law of England* (London, 1883), vol. iii. c. 26. Stephen finds in the laws of Alfred the earliest and most important recognition of the properly criminal consequences of homicide as distinguished from the damages to be paid to the family of the deceased and the compensation to be made to the person whose peace had been broken, which are the prominent points of the early law of homicide. (E. R.)

MURDOCK, WILLIAM (1754-1839), inventor, was born near the village of Auchinleck in Ayrshire on 25th August 1754. His father, John Murdoch (as the name is spelt in Scotland), was a millwright and miller, and William was brought up in the same occupation until 1777, when, at the age of twenty-three, he entered the employment of Boulton and Watts in the Soho Works at Birmingham. Shortly afterwards he was sent to Cornwall to superintend the fitting of Watts's engines, which had come to be in demand there. While staying at Redruth he had carried a series of experiments in the distillation of coal-gas so far that in 1792 he was able to apply the new invention to the purpose of lighting his cottage and offices; renewing his researches after his return to Birmingham (where he had become a partner in the firm), he made such progress in the discovery of practical methods for making, storing, and purifying the new illuminant that in 1802 the whole exterior of the factory was lighted with it in celebration of the peace of Amiens. Murdock was also the inventor of important improvements in the steam-engine; besides introducing the double D slide-valve, he was the first to devise an oscillating engine, and as early as 1784 he had constructed a model high-pressure engine to run on wheels. His inventive ingenuity was also directed to various applications of compressed air and of the exhausted air-tube; and in 1803 he also constructed a steam-gun. He retired from business in 1830, and died in 1839. His "Account of the Application of the Gas from Coal to Economical Purposes" appeared in the *Phil. Trans.* for 1808.

MURE, WILLIAM (1799-1860), historian of Greek literature, was born at the family seat near Caldwell, Ayrshire, Scotland, 9th July 1799. He was educated at Westminster school and Edinburgh, and he spent several years at the university of Bonn, where he laid the foundations of his classical knowledge. From 1846 to 1855 he represented the county of Renfrew in parliament in the Conservative interest, and he was lord rector of Glasgow

university in 1847-48. For many years he devoted his leisure to Greek studies, and in 1850-57 he published five volumes of a *Critical History of the Language and Literature of Ancient Greece*, which, however, he did not live to complete. While C. O. Müller's work, as translated and continued by Donaldson, is the best general history of Greek literature in English, Mure's treatment of the Homeric poems, of the lyric poets, and of the historians of the Attic period is the fullest in our language, and is everywhere marked by thorough knowledge, at first hand, of the Greek authors. Of the unity of the authorship of the *Iliad* and *Odyssey* he is a strenuous defender, attributing both to the one person, Homer. Colonel Mure was for many years commandant of the Renfrewshire militia. He died at London on 1st April 1860.

His other works are—*Remarks on the Chronology of the Egyptian Dynasties*, 1829; *Dissertation on the Calendar of the Zodiac of Ancient Egypt*, Edinburgh, 1832; *Journal of a Tour in Greece and the Ionian Islands* in 1838, Edinburgh, 1842. He also edited the *Caldwell Papers*, 3 vols., for the Maitland Club.

MURET, or MURETUS, MARC ANTOINE (1526-1585), French humanist, was born of respectable parentage at Muret near Limoges on 12th April 1526. Nothing is recorded of his early education, but at the age of eighteen he was already sufficiently accomplished to attract the notice of the elder Scaliger, and to be invited to prelect upon Cicero and Terence in the archiepiscopal college at Auch. He afterwards taught Latin at Villeneuve, and then at Bordeaux, where the youthful Montaigne was one of his pupils and played some of the principal parts in his Latin tragedies. Some time before 1552 he received a regency in the college of Cardinal Lemoine at Paris, and his brilliant lectures were largely attended, Henry II. and his queen being occasionally, it is recorded, among his hearers. His success seems to have excited more than the usual amount of envy; and in consequence of a disgraceful charge—which, however, was never established—he was thrown into prison. Here he had begun to carry out a resolution to starve himself to death, when the exertions of powerful friends procured his release. Hardly had he resumed lecturing at Toulouse when his career was again cut short by a new charge similar to that which had proved so disastrous at Paris; he saved his life by timely flight, but the records of the town bear that he was burned in effigy as a Huguenot and as shamefully immoral (1554). After a wandering and insecure life of some years in Italy, he received and accepted the invitation of the Cardinal d'Este to settle in Rome in 1559. Henceforward his life was one of unclouded prosperity. He was even able to revisit France in 1561 as a member of the cardinal's suite at the colloquy of Poissy. The interest shown in his lectures on the *Ethics* of Aristotle, and on the *Pandects*, almost recalled his early successes in Paris, and in 1578 his services as a teacher of jurisprudence were sought by the "natio Germanorum" studying law at Padua, and also by the king of Poland for his new college at Cracow. Muretus, however, who about 1576 had taken holy orders, was induced by the liberality of the pope to remain in Rome, where he died on 4th June 1585.

The first collected edition of the works of Muretus appeared at Verona in 1727-1730 (5 vols. 8vo); a more complete edition was published by Ruhnken at Leyden in 1789 (4 vols. 8vo); there is also an edition by Frotscher and Koch (3 vols., Leipsic, 1834-41), and two volumes of *Scripta selecta* have been edited by Frey (Leipsic, 1871-73). He annotated wholly or partially, in a learned and scholarly way that has proved more or less serviceable to subsequent editors, Terence, Horace, Catullus, Tibullus, Propertius, Tacitus, Sallust, Cicero, Aristotle, Xenophon. His other works include *Juvenilia et poemata varia*, *Orationes*, and *Epistolæ*. His merits as a stylist at one time secured for his *Orationes* a place among Latin school-books, but, although, according to his pupil Montaigne, he was recognized alike by France and Italy to be "the best orator of his time," the modern judgment must rather be in substance that of a later critic, that, if he "appears to have had a more delicate ear than almost any of the moderns and his Latinity surpasses in elegance that of any of the Romans themselves, excepting Cicero and Cæsar," he at the same time was "conceited, fantastical, and weakly-minded" (Landor, *Im. Conv.*, "Chesterfield and Chatham").

MURGER, HENRY (1822-1861), French man-of-letters, was born in February 1822 at Paris. His father was a *concierge*, with which employment he combined the trade of tailoring. At the age of fifteen Murger was sent into a lawyer's office, but the occupation was very uncongenial to him, and his father's trade still more so. He thus incurred the paternal displeasure, and in his devotion to literature and liberty began to meet with not a few of the hardships which he afterwards described. He was, however, for a time saved from actual want by the employment of secretary to the Russian Count Tolstoy, which was procured for him by M. de Jouy (an old academician of the classical faction, but a very kind friend to youthful literary aspirants) in the year 1838. For the next ten years little positive is known of Murger's life except that it probably provided the experiences, and certainly supplied him with the ideas, of his most famous book. He made his first independent appearance as an author in 1843 with a book entitled *Via Dolorosa*, but it made no mark. He also tried journalism, and the paper *Le Castor*, which figures in the *Vie de Bohême*, and which combined devotion to the interests of the hat trade with recondite philosophy and elegant literature, is said to have been a fact, though a shortlived one. At length he was introduced to better work, either in the *Corsaire*, then a favourite organ of the second romantic generation, or in the *Artiste*; for both stories are told. In 1848 appeared the collected sketches called the *Vie de Bohême*. This book, which is of its kind famous, describes the fortunes and misfortunes, the loves, studies, amusements, and sufferings, of a group of impecunious students, artists, and men of letters, of whom Rodolphe represents Murger himself, while the others have been more or less positively identified. Murger, in fact, belonged to a set or clique of so-called Bohemians, the most remarkable of whom, besides himself, were Privat d'Anglemont and Champfleury. The *Scènes de la Vie de Bohême* have been very variously judged. Their very easy-going morality, and the supposed danger of their pictures in prompting to imitation have prejudiced some readers against the book. It is fair, however, to Murger to say that he neither holds up the Bohemian as a hero, nor in the least disguises the hardship and the folly of his ways. He was himself an instance of the dangers of Bohemianism. From the date above mentioned it was perfectly easy for him to make a comfortable living by journalism and general literature. He was introduced in 1851 to the *Revue des Deux Mondes*, and contributed to it for two or three years, and he never had any difficulty in securing or keeping literary employment. But, he was a slow, a fastidious, and a very capricious worker, and his years of hardship and dissipation had very seriously impaired his health. He continued, however, to produce work pretty regularly, publishing *Claude et Marianne* in 1851, *Le Dernier Rendezvous* and *Le Pays Latin* in 1852, *Adeline Protat* (one of the most graceful and innocent if not the most original of his tales) in 1853, and *Les Buveurs d'Eau* in 1854. This last, the most powerful of his books next to the *Vie de Bohême*, exhibits a reverse side to the picture by tracing the fate of certain artists and students who, exaggerating their own powers and foolishly disdaining merely profitable work, come to an evil end not less rapidly if more respectably than by dissipation. Some years before his death, which took place in a *maison de santé* near Paris on 28th January 1861, Murger went to live at Marlotte, near Fontainebleau, and it was there that he wrote, and in 1859 published, an unequal book entitled *Le Sabot Rouge*,

in which the character of the French peasant is very uncomplimentarily treated. Besides the books already mentioned, Murger's published works fill several volumes of prose and one of verse. The poems contained in the latter (*Les Nuits d'Hiver*) are not very strong, but graceful and frequently pathetic. The prose volumes, with the exception of a novel of some scale, *Les Roueries de l'Ingénue* (which the author left unfinished at his death), consist almost exclusively of short tales in the manner, and more or less on the subject, of the *Vie de Bohême*. All exhibit the same characteristics—an excellent descriptive faculty, lively humour in drawing the follies of youth, frequently pathos, and not seldom a tender and poetical melancholy.

MURILLO, BARTOLOMÉ ESTEBAN (1617-1682), the greatest ecclesiastical painter of Spain, was the son of Gaspar Esteban Murillo and Maria Perez, and was born at Seville in 1617, probably at the very end of the year, as he was baptized on 1st January 1618. Esteban-Murillo appears to have been the compound surname of the father, but some inquirers consider that, in accordance with a frequent Andalusian custom, the painter assumed the surname of his maternal grandmother, Elvira Murillo, in addition to that of his father. His parents (of whom nothing distinct is known, save that they were of a humble class), having been struck with the precocious sketches with which the unlettered boy was accustomed to adorn whatever available surface came in his way, wisely resolved to place him under the care of their distant relative, Juan del Castillo, the painter. Juan, a correct draughtsman and dry colourist, taught him all the mechanical parts of his profession with extreme care, and Murillo proved himself an apt and docile pupil. The artistic appliances of his master's studio were by no means abundant, and were often of the simplest kind. A few casts, some stray fragments of sculpture, and a lay figure formed the principal aids available in those days for the Sevillian student of art. A living model was a luxury generally beyond the means of the school, but on great occasions the youths would strip in turn and proffer an arm or a leg to be studied by their fellows. Objects of still life, however, were much studied by Murillo, and he early learned to hit off the ragged urchins of Seville pursuing their adventures in the market-place. Murillo in a few years painted as well as his master, and as stiffly. His two pictures of the Virgin, executed during this period, show how thoroughly he had mastered the style, with all its defects. Castillo was a very kind man, but his removal to Cadiz in 1639-40 threw his favourite pupil entirely upon his own resources. The fine school of Zurbaran was too expensive for the poor lad; his parents were either dead or too poor to help him, and he was compelled to earn his bread by painting rough pictures for the "feria" or public fair of Seville. The religious daubs exposed at that mart were generally of as low an order as the prices paid for them by their rude purchasers. A "pintura de la feria" (a picture for the fair) was a proverbial expression for an execrably bad one; yet the street painters who thronged the market-place with their "clumsy saints and unripe Madonnas" not unfrequently rose to be able and even famous artists. This rough-and-ready practice, partly for the market-place, partly for converts in Mexico and Peru, for whom Madonnas and popular saints were produced and shipped off by the dozen, doubtless increased Murillo's manual dexterity; but, if we may judge from the picture of the Virgin and Child still shown in the Murillo-room at Seville as belonging to this period, he made but little improvement in colouring or in general strength of design. Struck by the favourable change which travel had wrought upon the style of his brother artist Pedro de Moya, Murillo in 1642 resolved to make a journey to Flanders or Italy in quest of further insight into art. But how was he, already struggling for existence and with a poor sister dependent on him, to raise the means necessary for such an expedition? Having bought a large quantity of canvas, he cut it into squares of different sizes, which he converted into pictures of a kind likely to sell. The American traders at once bought up his pieces, and he now found himself sufficiently rich to carry out his much-cherished design. He placed his sister under the care of some friends, and without divulging his plans to any one set out for Madrid. On reaching the capital he waited on Velazquez, his fellow-townsman, the great court-painter, then at the summit of his fortune, and, communicating to him his simple story, asked for some introduction to friends in Rome. The master liked what he saw of the manly youth, and in the noblest manner offered him lodging in his own house, and proposed to procure him admission to the royal galleries of the capital. Murillo accepted the offer, and here enjoyed the masterpieces of Italy and Flanders without travelling beyond the walls of Madrid. The next two years were chiefly spent in copying from Ribera, Vandyck, and Velazquez; and in 1644 he so greatly astonished the latter with some of his efforts that they were submitted to the inspection of the king and the court. His patron now urged him to go to Rome, and offered him letters to smooth his way; but Murillo, from whatever cause, preferred returning to his sister and his native Seville.

The friars of the convent of San Francisco in Seville had about this time piously determined to adorn the walls of their small cloister in a manner worthy of their patron saint. But the brotherhood had no money; and after endless begging they still found themselves incapable of employing an artist of name to execute the task. Murillo was needy, and offered his services; after balancing their own poverty against his obscurity the friars bade him begin. Murillo covered the walls with eleven large pictures of remarkable power and beauty,—displaying by turns the strong colouring of Ribera, the life-like truthfulness of Velazquez, and the sweetness of Vandyck. Among them were to be found representations of San Francisco, of San Diego, of Santa Clara, and of San Gil. These pictures were executed in his earliest style, commonly called his *frio* or cold style. It was based chiefly on Ribera and Caravaggio, and was dark with a decided outline. This rich collection is no longer to be met with in Seville; Marshal Soult carried off ten of the works. The fame of these striking productions soon got abroad, and "El Claustro Chico" swarmed daily with artists and critics. Murillo was no longer friendless and unknown. The rich and the noble of Seville overwhelmed him with their commissions and their praises.

In 1648 Murillo married a wealthy lady of rank, Doña Beatriz de Cabrera y Sotomayor, of the neighbourhood of Seville, and his house soon became the favourite resort of artists and connoisseurs. About this time he was associated with the landscape-painter Yriarte—the two artists interchanging figures and landscapes for their respective works; but they did not finally agree, and the co-operation came to an end. Murillo now painted the well-known Flight into Egypt, and shortly afterwards changed his earliest style of painting for his *calido* or warm style. His drawing was still well defined, but his outlines became softer and his figures rounder, and his colouring gained in warmth and transparency. His first picture of this style, according to Cean Bermudez, was a representation of Our Lady of the Conception, and was painted in 1652 for the brotherhood of the True Cross; he received for it 2500 reals (£26). In 1655 he executed his two famous paintings of San Leandro and San Isidoro at the order of Don Juan Federigo, archdeacon of Carmona, which are now to be seen in the cathedral of Seville. These are two noble

price on record was given in 1852, some £24,600. His subjects may be broadly divided into two great groups—the scenes from low life (which were a new kind of experiment in Spanish art, so far as the subjects of children are concerned), and the Scriptural, legendary, and religious works. The former, of which some salient specimens are in the Dulwich Gallery, are, although undoubtedly truthful, neither ingenious nor sympathetic; sordid unsightliness and roguish squalor are their foundation. The children have little of the charm of childhood, and none of its auroral promise. The embodiments are accurate and knowing studies of ungainliness. Works of this class belong mostly to the earlier years of Murillo's practice. The subjects in which the painter most eminently excels are crowded compositions in which some act of saintliness, involving the ascetic or self-mortifying element, is being performed,—subjects which, while obtrusively repulsive in some of their details, emphasize at once the broadly human and the expressly Catholic conceptions of life. A famous example is the picture, now in the Madrid academy, of St Elizabeth of Hungary washing patients afflicted with the scab or itch, and hence commonly named El Tiñoso. Technically considered, it unites his three styles of painting, more especially the cold and the warm. His power of giving atmosphere to combined groups of figures is one of the marked characteristics of Murillo's art; and he may be said to have excelled in this respect all his predecessors or contemporaries of whatever school.

Seville must still be visited by persons who wish to study Murillo thoroughly, and to relish the full and native flavour of his art. A large number of the works which used to adorn this city have, however, been transported elsewhither. In the Royal Gallery at Madrid are forty-five specimens of Murillo—the Infant Christ and the Baptist (named Los Niños della Concha), St Ildefonso vested with a Chasuble by the Madonna, &c.; in the Museo della Trinidad, Christ and the Virgin appearing to St Francis in a Cavern, an immense composition, and various others. In the London National Gallery the chief example is the Holy Family; this was one of the master's latest works, painted in Cadiz. Murillo, who was the last pre-eminent painter of Seville, was an indefatigable and most prolific worker, hardly leaving his painting-room save for his assiduous devotions in church; he realized large prices according to the standard of his time, and made a great fortune. His character is recorded as very amiable and soft, yet not the less independent, subject also to sudden impulses, not unmixed with gusts of passion.

For further information see, especially, Stirling, *Annals of the Artists of Spain*, 3 vols., London, 1848; Richard Ford, *Handbook for Spain*, London, 1855; and Curtis, *Catalogue of the Works of Velazquez and Murillo* (1883). (W. M. R.)

MUROM, a district town of Russia in the province of Vladimir, on the craggy left bank of the Oka close by its junction with the Tesha, 107 miles by rail south-east of Vladimir. Murom is the chief entrepôt for grain from the basin of the lower Oka and carries on an active trade with Moscow and Nijni-Novgorod, partly by the Oka, partly by rail, a branch line to Kovroff connecting it with the railway between the towns just mentioned. Murom is still famed, as in ancient times, for kitchen-gardens, raising especially cucumbers and seed for canary-birds. Its once famous tanneries have lost their importance, but the manufacture of linen has greatly increased; it has also steam flour-mills, distilleries, manufactories of soap, &c., and of iron implements. There are also several distilleries in the district. The population is 11,000.

MURPHY, Arthur (1727-1805), dramatist, was the son of a Dublin merchant, and was born near Elphin in Roscommon in 1727. From 1740 to 1747 he was a student at St Omer (France). He then entered the counting-house of his uncle, a merchant at Cork. But four years afterwards he was in London, prosecuting literature as a profession and publishing *The Gray's Inn Journal*, a periodical in the style of *The Spectator*. The drama was also occupying his attention. He produced the farce of *The Apprentice*, and appeared as an actor in the character of Othello. His dramas were more successful than his acting. After treading the stages of Covent Garden and Drury Lane for one season each, he abandoned the profession. His next undertaking was the editing of a political periodical called *The Test*. In this, too, he was unsuccessful. He next turned his attention to the study of law, and was called to the bar by the Society of Lincoln's Inn in 1757. But the smallness of his practice forced him to have recourse to his former vocation of writing for the stage. Among his many popular dramas, *The Upholsterer*, in 1758; *The Way to Keep Him*, in 1760; *All in The Wrong*, in 1761; *The Grecian Daughter*, in 1772; and *Know Your Own Mind*, in 1777, were very successful, and secured for their author both fame and wealth. Murphy is also notable as the first biographer of Fielding, and amidst the miscellaneous literary work of his later years he produced an "essay on the life and genius" of Johnson and translations of Sallust and Tacitus. Towards the close of his life the office of a commissioner of bankrupts, and a pension of £200, were conferred upon him by Government. He died in June 1805.

MURPHY, Robert (1806-1843), mathematician, was the son of a poor shoemaker, and was born at Mallow in Ireland in 1806. At the age of thirteen, while working as an apprentice in his father's shop, he became known to certain gentlemen in the neighbourhood as a self-taught mathematician of wonderful precocity. Through their exertions, after attending a classical school in his native town, he was admitted to Caius College, Cambridge, in 1825. Third wrangler in 1829, he was elected in the same year a fellow of his college. But the temptations of prosperity were too strong for him. A course of extravagant dissipation soon led him into debt; his fellowship was sequestered for the behoof of his creditors, and he was obliged to leave Cambridge in December 1832. After living for some time with his relations in Ireland, he repaired to London in 1836, a penniless literary adventurer. He had already contributed several mathematical papers to the *Cambridge Philosophical Transactions*, and had published *Elementary principles of the theories of Electricity*, &c., Camb., 1833. His pen was now employed in writing for the "Library of Useful Knowledge" a *Treatise on the Theory of Algebraical Equations* (Lond., 1839). He was labouring diligently to throw off the load of debt that still pressed heavily upon him when a disease of the lungs cut short his career in March 1843.

Murphy's mathematical writings are remarkable for elegance and ingenuity, and parts of his work on the theory of equations and on the mathematical theory of electricity still retain their importance.

MURRAIN, a term usually restricted to extensive outbreaks of disease in cattle, but also applied to serious disorders among sheep and pigs, is taken in this article to cover general or infectious disorders of all the domesticated animals, and as synonymous with plague or epizooty.

It is now an established fact that murrains are all infectious, *i.e.*, capable of transmission from diseased to healthy creatures of the same, or perhaps of many different species, the manner and degree of infectiousness varying somewhat in some of the disorders. It is also an established fact that several of them—and presumably all—owe their existence and spread to a micro-organism or germ, vegetable or animal in its nature, which, obtaining access to a healthy body disposed to its reception, grows and multiplies rapidly there, and produces characteristic morbid symptoms and alterations in tissues and organs. On the presence and dissemination of this germ or virulent agent these diseases depend for their continuance and extension; and this knowledge furnishes us with the indications for the sanitary measures required to limit their spread, or to effect their extermination.

In previous ages the great outbreaks of murrains only occurred at comparatively rare intervals, in regions more or less remote from those to which they were native; and then they generally owed their diffusion to the events of war, which sometimes carried them far beyond their ordinary boundaries. In modern times their extension has been greatly facilitated by the vastly improved means of communication. The movement of large numbers of animals through the channels of commerce and their rapid transport from

one country to another, their concentration in markets, their incessant renewal, the mixing of native with foreign animals, a general indifference to the existence of contagious diseases and the losses they might inflict, the absence of anything like an organization to control and regulate this movement, carry out sanitary regulations, and investigate and suppress these murrains—all these have operated in rendering some of the most harassing and destructive scourges more or less cosmopolitan, spreading them from a very limited area in the middle of a continent to every quarter of the globe, where they flourish as vigorously and persistently as if indigenous to the soil.

The best-known murrains are discussed below.

1. *Anthrax.*—This is one of the most diffused and interesting of murrains, affecting, as it does, wild as well as domesticated animals. It prevails, in one or more of its forms, over the entire surface of the globe. It at times decimates the reindeer herds in Lapland and the Polar regions, and is only too well known in the tropics and in temperate latitudes. It has been observed and described in Russia, Siberia, Central Asia, China, Cochin China, Egypt, West Indies, Peru, Paraguay, Brazil, Mexico, and other parts of North and South America, in Australia, and on different parts of the African continent, while for other European countries the writings which have been published with regard to its nature, its peculiar characteristics, and the injury it inflicts are innumerable. Countries in which are extensive marshes, or the subsoil of which is tenacious or impermeable, are usually those most frequently and seriously visited. Thus there are regions notorious for the prevalence of this murrain, such as the marshes of Sologne, Dombes, and Bresse in France; certain parts of Germany, Hungary, and Poland; in Spain it is severely felt in the half-submerged valleys and the maritime coasts of Catalonia, as well as in the Romagna and other marshy districts of Italy; while it is epizootic, and even panzootic, in the swampy regions of Esthonia, Livonia, Courland, and especially of Siberia, where it is known as the *Sibirskaja jaswa* (Siberian boil-plague), and where it sometimes happens that, in order to suppress its ravages, battalions of soldiers must be sent to bury or burn the carcases of infected animals which float in the canals or lie in the swamps, rendering the air and the water pestilent. The records of the anthrax go back to a very ancient date. It is supposed to be the murrain of Exodus. Classical writers allude to the anthrax as if it were the only cattle

quickly (in

a few minutes) that there is no time to afford relief. One or more of the best-conditioned and perhaps robust animals in a herd or flock, which until then exhibited no sign of the disease, are suddenly struck down as if shot while grazing, feeding in the stable, or travelling, and rise no more. Or they commence all at once to tremble and stagger; the breathing becomes hurried and the pulse very rapid, while the heart beats violently; the internal temperature of the body is high; blood flows from the nose, mouth, and anus; the visible mucous membranes are almost black in tint; and death soon supervenes, being immediately preceded by delirium, convulsions, or coma. In some cases the animal rallies from a first attack, but soon a second ensues, to which it speedily succumbs, the creature in the interval remaining drowsy and showing muscular tremors. In the carbuncular form the tumours may appear in any part of the body, being preceded or accompanied by fever. When the tongue is affected, the disease is usually known as blain of the tongue, tongue evil, or glossanthrax.

The tumours or malignant pustules are developed in the subcutaneous connective tissue, where this is loose and plentiful, in the interstices of the muscles, and in the lymphatic glands. In the various animals affected they have their special affinities for certain regions, as between the branches of the lower jaw, upper part of the throat, lower portion of the neck, breast, behind the shoulders, back, flank, substance of the tongue, &c. If the part where an anthrax tumour is about to appear is covered with hair, this will be observed to become erect, and if the hand is passed over the part perhaps a slight crepitation will be felt; there is also increased sensibility. In many cases there soon appears a nodosity, simple or multiple, about the size of a small nut and circular or irregular in outline. Ordinarily this is little sensitive in itself, the pain the animal experiences being due to the increased sensibility of the surrounding parts. In other instances the tumour suddenly commences in the appearance of a soft œdematous swelling, crepitating and undefined. When the eruption takes this form the tumours are quickly developed, and in a few hours invade all the neighbouring parts, extending in every direction with equal rapidity,—the skin covering them becoming tense and hard like parchment, and crackling on pressure. As they extend they become cold and insensible, a variable number of phlyctænæ arise on their surface, and these quickly bursting give issue to a serous irritant fluid. If an incision is made in the swelling at this stage there is no symptom of pain, and a black or reddish serum escapes, extremely fœtid and corrosive, which produces a noise as it flows like the crackling of paper or the bubbling of boiling water. Sometimes passive hæmorrhage ensues after the incision is made, and continues until death.

In whatever form the tumours are developed, their course is always the same, being more rapid the earlier they appear. In from two to eight hours they attain a considerable size, and the tissues mortify as they are invaded. As they are developed the animal seems to become relieved, the fever abates, and the more urgent symptoms vanish. But, when they have attained certain proportions, general symptoms are manifested, and these vary according as the malady is to terminate favourably or otherwise. In some rare instances the matter which constitutes the tumours is suddenly absorbed, abundant sweats, an increased flow of urine, or a serous fœtid diarrhœa ensue, and the animal promptly recovers. In other cases, by surgical intervention, the evolution of the tumours is limited to a certain extent; they reach the suppurative stage, and finally disappear. In ordinary circumstances, however, it happens that after the interval which follows the eruption, the organism being incapable of eliminating the morbid element, the tumours vanish; but this is only a transference, for the disease assumes all the grave characters of anthrax fever without local manifestations, the general symptoms reappear, and, running their course with marvellous rapidity, the animal perishes in a few hours.

A form of anthrax affects the horse more especially, and this by some authors has been designated anthrax typhus. It manifests itself locally and generally, and is very fatal (Fleming, *Veterinary Sanitary Science and Police*, vol. ii. p. 122).

In cattle there is a disease very fatal among young stock, and known to breeders and graziers by various names, the most common of which is "black quarter," which had always been classed among the forms of anthrax until its nature was investigated by Arloing and Cornuvin, who have termed it symptomatic anthrax (*Charbon symptomatique*), while by others it has been named anthracoid erysipelas, &c. This is at first a local disease, affecting usually one hind quarter, and occurring among young animals more especially, particularly those fed on rich food and thriving rapidly. It also occurs very suddenly, runs its course in a very brief space, and nearly always terminates fatally unless surgical and medical treatment is promptly resorted to. It is caused also by a bacillus or bacterium somewhat different from that of ordinary anthrax.

In splenic fever or splenic apoplexy, the most marked alterations observed after death are—the effects of rapid decomposition, evidenced by the foul odour, disengagement of gas beneath the skin and in the tissues and cavities of the body, yellow or yellowish-red gelatinous exudation into and between the muscles, effusion

of citron- or rust-coloured fluid in various cavities, extravasations of blood and local congestions throughout the body, the blood in the vessels generally being very dark and tar-like. The most notable feature, however, in the majority of cases is the enormous enlargement of the spleen, which is engorged with blood to such an extent that it often ruptures, while its tissue is changed into a violet or black fluid mass.

Inoculation.—Anthrax in all its forms is an inoculable disease, transmission being surely and promptly effected by this means, and it may be conveyed to nearly all animals either by inoculation or through the digestive organs. The abraded skin is often the channel for the introduction of the bacilli; and persons who handle diseased animals or their products—as flesh, skin, wool, or hair—often die from anthrax, which presents similar symptoms in mankind to those it exhibits in animals. The bacillus of anthrax, under certain conditions, retains its vitality for a long time, and rapidly grows when it finds a suitable fluid in which to develop, its mode of multiplication being by scission and the formation of spores, and depending, to a great extent at least, on the presence of oxygen. The morbid action of the bacillus is indeed said to be due to its affinity for oxygen; by depriving the red corpuscles of the blood of that most essential gas, it renders the vital fluid unfit to sustain life. Others assert that the fatal lesions are produced by the enormous number of bacilli blocking up the minute blood-vessels, especially of the lungs, and thus inducing asphyxia.

It was by the cultivation of this micro-organism, or attenuation of the virus, that Pasteur has been enabled to produce a prophylactic remedy for anthrax, which has already been demonstrated to be very effective; and his discovery is likely to lead to most important results in procuring protective agents for other similar and fatal disorders in man and beast. Though his discovery was first made with regard to the cholera of fowls, a most destructive disorder which annually carries off great numbers of poultry, yet as applied to anthrax it has attracted most attention. This so-called attenuation or cultivation of the virus of the disease by Pasteur is effected by growing the bacillus in an albuminous fluid, the preference being given to chicken-broth which has been previously sterilized by being raised to a temperature of 115° C. This broth is inoculated with a drop of anthrax blood which has been taken with antiseptic precautions from an animal about to die of the disease; it is kept in pure air at a temperature of 42° to 43° C.; at 45° the process of cultivation will not go on. After a certain time another quantity of broth is inoculated with a drop of the first, and kept under the same conditions; and so this cultivation is carried on until a sufficient number of generations of the bacilli have been grown and the required degree of attenuation ensured. This is attained by attention to the temperature, allowing a certain interval to elapse between each inoculation of the broth and the number of generations cultivated. The resulting "vaccine," as it has been improperly designated, when inoculated into the body of an animal liable to anthrax, confers immunity from the disease, if certain rules are attended to.

Toussaint had, previous to Pasteur, attenuated the virus of anthrax by the action of heat; and Chauveau has more recently corroborated by numerous experiments the value of Toussaint's method, demonstrating that, according to the degree of heat to which the virus is subjected, so its innocuousness when transferred to a healthy creature. The attenuation of heat, according to this method, is a safer and readier way to obtain a protective virus than Pasteur's broth cultivations.

2. *Cattle-Plague or Rinderpest.*—The next disease is that which has, since the commencement of the last century, been generally described as "the murrain," but which is now better known as the "cattle-plague" or "rinderpest" (German). While anthrax is, with regard to species of animals attacked, the most universal of all diseases, being transmissible to nearly every living creature, including mankind, cattle-plague is limited to ruminants (oxen, sheep, goats, camels, buffaloes, yaks, deer, &c.). It is an Asiatic malady, and prevails frequently and with great severity in southern Russia (imported), Central Asia, Mongolia, China (south, west, and north), Cochin China, Burmah, Hindustan, Persia, Ceylon, and the islands in the Indian and Malay Archipelagos. It is only known in Europe as an exotic and imported malady, it has not yet appeared on the American continent, in Australia, in New Zealand, or on the African continent, except in Egypt, into which it has been carried on several occasions, and where, owing to the absence of sanitary measures, it now prevails constantly. It is one of the most infectious and fatal diseases of animals—a specific fever which runs its course so rapidly, and attacks such a large percentage of ruminants when it is introduced into a country, that from the earliest times it has excited terror and dismay.

It has been noted that its irruptions into Europe in the earlier centuries of our era always coincided with invasions of barbarous tribes in the east of Europe; and even at a later period the disease accompanied the events of war, when troops with their commissariat moved from the east towards the west, or cattle, when they were carried in the same direction. One of the earliest recorded irruptions of cattle-plague into western Europe occurred in the 5th century after the sanguinary invasion of the Huns under Attila, the expulsion of the Goths from Hungary, and the fierce internecine wars of the whole Germanic population. The disease appears then to have been carried from Hungary through Austria to Dalmatia, while by Brabant it obtained access to the Low Countries, Picardy, and so on to the other provinces of France. In the curious poem *De Mortibus Bovum* written by St Severus, who lived at that period, the course and destructiveness of the disease are specially alluded to. Many invasions of Europe are described, and in several of these Britain was visited by it—as in 809-810, 986-987, 1223-1225, 1513-1514, and notably in 1713, 1745, 1774, 1799. In 1865 and 1872 it was imported direct from Russia.

Symptoms.—Like some other general diseases, this does not offer any exclusive or pathognomonic symptoms, but is rather characterized by a group of functional and anatomical alterations. An exact knowledge of its symptoms and necroscopical appearances is of the utmost importance, as its extension and consequent ravages can only be arrested through its timely recognition and the immediate adoption of the necessary sanitary measures. Intense fever, diarrhœa or dysentery, croupous inflammation of the mucous membranes in general, sometimes a cutaneous papular eruption, and great prostration mark the course of the affection, which is frequently most difficult to diagnose during life, especially if its presence is not suspected. Its introduction and mode of propagation can, in many instances, be ascertained only at a late period, and when great loss may already have been sustained. In the majority of cases the examination of the carcase of an animal which has died or been purposely killed is the best way to arrive at a correct diagnosis. Indeed, this is practically the only certain means of concluding as to the presence of the malady, as in different invasions, and even in different countries and different individuals during the same invasion, there are observed considerable variations in the chief symptoms with regard to their intensity as well as in the secondary symptoms or epiphenomena.

Among cattle indigenous to the regions in which this malady may be said to be enzootic the symptoms are often comparatively slight, and the mortality not great. So much is this the case that veterinary surgeons who can readily distinguish the disease when it affects the cattle of western Europe, can only with difficulty diagnose it in animals from Hungary, Bessarabia, Moldavia, or other countries where it is always more or less prevalent. In these the indications of fever are usually of brief duration, and signs of lassitude and debility are, in some instances, the only marks of the presence of this virulent disorder in animals which may, nevertheless, communicate the disease in its most deadly form to the cattle of other countries. Slight diarrhœa may also be present, and a cutaneous eruption accompanied by gastric disturbance, shedding of tears, and infrequent cough. In the more malignant form the fever runs very high, sometimes to 107·6° Fahr., and all the characteristic symptoms of the disorder are well marked, the lesions during life being observed in the cheese-like deposits on the gums, the presence of petechiæ on the mucous membranes, discharges from the eyes, nose, and mouth, eruption on the skin, cough and laboured breathing, certain nervous phenomena, and dysenteric dejections. Death generally occurs in four or five days, the course of the disorder being more rapid with animals kept in stables than with those living in the open air, and in summer than in winter. After death the chief alterations are found in the digestive canal, and consist in evidence of inflammation of a more or less acute kind, with ulceration, extravasation of blood, gangrene, &c. The membrane lining the air-passages offers similar alterations; indeed, all the mucous membranes of the body appear to be involved, and the malady might almost be considered as a malignant infectious catarrhal fever.

Protective inoculation has often been advocated and practised (particularly in Russia) for this disorder, but the advantages derived have not been sufficient to compensate for the danger attend-

ing it. Quite recently, Semmer of the Dorpat veterinary school has made experiments with cultivated or attenuated virus, and so far the results have been encouraging.

3. *Pleuro-Pneumonia or Lung-Plague.*—The next murrain in importance, with regard to destructiveness, is the so-called "lung-plague" or contagious "pleuro-pneumonia" of cattle.

This disease is particularly interesting from the fact that within less than two centuries it has been spread from a very small area over nearly every part of the world. The earliest notices of it testify that it first prevailed in central Europe, and in the last century it was present in certain parts of southern Germany, Switzerland, and France, and had also appeared in upper Italy. Though Valentine described an epizooty occurring among cattle in 1693 in Hesse, yet doubts have been entertained as to whether it was this malady. It was not until 1769 that it was definitely described as prevailing in Franche-Comté by the name of "murie." From that date down to 1789 it appears to have remained more or less limited to the Swiss mountains, the Jura, Dauphiné, the Vosges, Piedmont, and upper Silesia; it showed itself in Champagne and Bourbonnais about the time of the Revolution, when its spread was greatly accelerated by the wars that followed, and the consequent demand for cattle for the commissariat parks of the contending armies. Since that time the continually increasing commercial relations between various countries have carried it to the ends of the earth, the long duration of latency, and the somewhat slow course of the disorder, eminently adapting it for conveyance to great distances. In this century its diffusion has been accurately determined. It invaded Prussia in 1802, and soon spread over North Germany. It was first described as existing in Russia in 1824; it reached Belgium in 1827, Holland in 1833, the United Kingdom in 1841, Sweden in 1847, Denmark in 1848, Finland in 1850, South Africa in 1854, the United States —Brooklyn in 1843, New Jersey in 1847, Brooklyn again in 1850, and Boston in 1850; it was also carried to Melbourne in 1858, and to New South Wales in 1860; New Zealand received it early in 1864. It has also been carried to Asia Minor, and has made its presence felt at Damascus. In Austria it is less prevalent than in some other European countries, being scarcely known except in Bohemia, Moravia, and a portion of Tyrol. In Hungary it appears to be almost unknown, in consequence of the minimum importation of foreign cattle; and in countries to which it has not been introduced by infected animals it is not seen. In consequence of its insidious invasion, the subtlety of its contagion, and the great fatality attending it, there can be no doubt that it is one of the most disastrous plagues that can afflict a cattle-producing country. Fortunately, unlike the two preceding murrains, it is confined entirely to the bovine species; no well-authenticated instances of its transmission, either accidental or experimental, to other species have been recorded.

In its nature it is a specific infectious disease, generally affecting the lungs and the lining membrane of the chest, producing a particular form of lobar or lobular pleuro-pneumonia, and in the majority of cases, if not in all, it is transmitted through the medium of the inspired air,—hence its localization in the lungs. Inoculation with the fluid from the diseased lungs does not produce any effect on other than the bovine species; but in this its action is most energetic. Producing, after a certain interval, characteristic lesions at the seat of inoculation, the morbid change or infective process soon involves parts beyond, and if not checked may cause most serious damage and even the death of the inoculated animal; though it does not develop the lung lesions always observed in accidental infection, yet there is a local anatomical similarity or identity.

Symptoms.—The malady is slow and insidious in its course, lasting from two to three weeks to as many months, the chief symptoms being fever, diminished appetite, a short cough of a peculiar and pathognomonic character, with quickened breathing and pulse, and physical indications of lung and chest disease. The progress of the malady is marked by exacerbation of the symptoms, and towards the end there is great debility and emaciation, death generally ensuing after hectic fever has set in. Recovery is somewhat rare.

The pathological changes are generally limited to the chest and its contents, and consist in a peculiar marbled-like appearance of the lungs on section, and fibrinous deposits on the pleural membrane, with oftentimes great effusion into the cavity of the thorax.

Willems of Hasselt (Belgium) in 1852 introduced and practised inoculation as a protective measure for this scourge, employing for this purpose the serum obtained from a diseased lung; and his success was so marked that he made known his procedure. Since that time inoculation has been extensively resorted to, not only in Europe, but also in Australia and South Africa; and its protective value has been generally recognized. When properly performed, and when certain precautions are adopted, it would appear to confer immunity from the disease. The usual seat of inoculation is the extremity of the tail, the virus being introduced beneath the skin by means of a syringe or a worsted thread impregnated with the serum. One or two drops are sufficient to cause the local and constitutional disturbance which mark successful prophylactic infection. A particular micro-organism has been discovered in the diseased textures and fluids of animals affected with contagious pleuro-pneumonia, which is supposed to cause the malady. It has been cultivated, and inoculation experiments have been made with it. The intravenous injection of the virus has been found to be a safer method of conferring immunity than inoculation beneath the skin, and quite as certain a method.

4. *Foot-and-Mouth Disease* (Epizootic Aphtha, Eczema epizootica), if we were to judge by the somewhat vague descriptions of different disorders by Greek and Roman writers, has been a European malady for more than 2000 years. But no reliance can be placed on this evidence, and it is not until we reach the 17th and 18th centuries that we can find trustworthy proof of its presence, when it was reported as frequently prevailing extensively in Germany, Italy, and France. During this century, owing to the vastly-extended commercial relations between every civilized country, it has, like the lung-plague, become widely diffused. In the Old World its effects are now experienced from the Caspian Sea to the Atlantic Ocean. It gradually extended towards Britain at the commencement of this century, after invading Holland and Belgium, and about 1839 appeared in England, where it was immediately recognized as a new disease; it quickly spread over the three kingdoms. From the observations of the best authorities it would appear to be an altogether exotic malady in the west of Europe, always invading it from the east; at least, this has been the course noted in all the principal invasions. It was introduced into Denmark in 1841, and into the United States of America from Canada, where it had been carried by diseased cattle from England. It rapidly extended through cattle traffic from the State first invaded to adjoining States, but was extinguished, and does not now appear to be known on the American continent. It was twice introduced into Australia in 1872, but was stamped out on each occasion. It appears to be well known in India, Ceylon, Burmah, and the Straits Settlements. In 1870 it was introduced into the Andaman Islands, where it had not previously been seen, by cattle imported from Calcutta, where it was then prevailing. There is evidence that it is common in South Africa, and is frequently epizootic there, causing great inconvenience, owing to the bullocks used for draught purposes, which travel great distances, becoming unfit for work, by which traffic is much interfered with. These cattle also spread the contagion. It is not improbable that it also prevails in Central Africa, as Schweinfurth alludes to the cattle of the Dinkas suffering from a disease of the kind. Though not a fatal malady, and in the majority of cases readily amenable to treatment, yet it is a most serious scourge. It is transmissible to nearly all the

domestic animals, even mankind sometimes becoming infected, but its ravages are most severe among cattle, sheep, and pigs. Since it was introduced into the United Kingdom it has proved more disastrous on the whole, perhaps, than any other murrain, and has most injuriously affected agricultural interests. What makes it more serious is the fact that one attack is not protective against another, an animal sometimes being affected a second time within a few months.

Symptoms.—This is an eruptive fever, characterized by vesicles or blisters in the mouth, sometimes in the nostrils, and on parts of the body where the skin is thin and least covered with hair, as on the udder and towards the feet. The animal cannot eat so well as usual, suffers much pain and inconvenience, loses condition, and, if a milk-yielding creature, gives less milk, or, if pregnant, may abort. Sometimes the feet become very much diseased, and the animal is so crippled that it has to be destroyed. It is often fatal to young creatures. It is transmitted more especially by the saliva and the discharges from the vesicles on the feet and udder, though all the secretions and excretions are doubtless infective, as well as all articles soiled by them. The disease can be produced by injecting the saliva intravenously.

These are the best-known murrains affecting cattle; but there are others which, though they cannot be noticed here, are of some moment. One in particular demands most serious consideration, the disease known as "consumption," "pining," and (from the appearance of the morbid growths in the chest) "grapes," and to the medical and veterinary pathologist as "tuberculosis." It is a highly-infectious disorder in cattle, is becoming very common among the improved breeds, and causes heavy losses in dairy stock. It has been experimentally demonstrated that the tuberculous matter, as well as milk and the juice of the flesh of diseased cows, when given to healthy animals or inoculated in them, will produce the malady, and this leads to the grave question as to the danger incurred by mankind through the consumption of the flesh and milk of tuberculous cows. This is a pressing sanitary problem which demands early solution.

Prevention of Murrains.—The legislative measures necessary for prevention or suppression of murrains are based upon the fact that these diseases depend for their extension solely upon their contagious properties. The object is, therefore, either to prevent the admission of the contagious principle, *i.e.*, through diseased animals or articles which have become infective by contact with them, or to destroy it as quickly as possible. The necessity for this is abundantly evident on every page in the history of these scourges. It is almost impossible to realize the loss and embarrassment caused by cattle-plague, lung-plague, and foot-and-mouth disease only. By the first-named murrain it has been estimated that the loss in Europe from 1711 to 1796 only was 200,000,000 head of cattle. And in this century the disease has not been less severe, though its opportunities for extension, much greater than before, have been much diminished by the progress made in veterinary science. From 1841 to 1844 Egypt lost 400,000 head of cattle; and 1,000,000 perished in Russia in 1844-1845. From 1849 to 1863 the Austrian states lost 258,107. In Hungary from 1861 to 1867 this steppe murrain appeared in 680 communes having a bovine population of 908,209; 25 per cent. were attacked, and of these 145,474 or 63·9 per cent were lost. In 1860-1861 Austria lost 4800 cattle; and in Russia 183,678 died in 1860. In 1865-1866 Great Britain is supposed to have lost 233,629 head, valued at from five to eight millions of pounds, though this is probably far below the actual figure; and Holland, receiving the infection from England, at this time lost 115,000 cattle. In 1870 Germany reported 8122 as dead from rinderpest; and during the Franco-German war, when the disease was introduced into France by the German troops, the Bas-Rhin department alone lost 6104 cattle and sheep at the period of the invasion, and 582 cattle and 944 sheep when the troops returned, the amount of indemnity paid for cattle destroyed being 1,622,249 francs, while in Lorraine 5000 cattle and more than 3000 sheep, and in the Haut-Rhin 14,000 cattle perished, the compensation to cover this loss being estimated at 1,500,000 francs. In August 1873 thirteen governments in Russia were invaded by rinderpest, and it was computed that 18,000 animals were attacked, 14,000 of which died or were destroyed.

These figures give but a faint idea of the appalling destruction wrought by rinderpest; and lung-plague, though its ravages are not so striking or immediate, has been scarcely less formidable. For instance, in Holland in 230 parishes the average yearly loss has been reckoned at 49,661. In 705 parishes in Wurtemberg 1706 stables contained 10,214 cattle; of these 4200 were attacked, and 2583 were killed or died. In France, according to published statistics, the loss caused by this murrain in 217 communes of the department of the Nord during seven consecutive years was 11,200 in a bovine population of 280,000—or a total in nineteen years of 218,000 head, the estimated value of which was fifty-two millions of francs. In the departments of Aveyron, Cantal, and Lozère the average loss for a long time was not less than 35 per cent. of the entire cattle. In Australia the losses caused by it during thirteen years were supposed to be at least 30 to 40 per cent. of the whole number of cattle, or about 1,404,097 head, which, if valued at only £6 each, would amount to about £8,500,000. Only a very imperfect notion can be formed of the destruction it has caused in Great Britain and Ireland since its introduction; but for the six years ending with 1860 it has been calculated that there perished considerably more than a million of cattle in the United Kingdom, the value of which must have amounted to more than twelve millions of pounds. From 1863 to 1866 the death-rate from the scourge was from 50 to 60 per cent. annually.

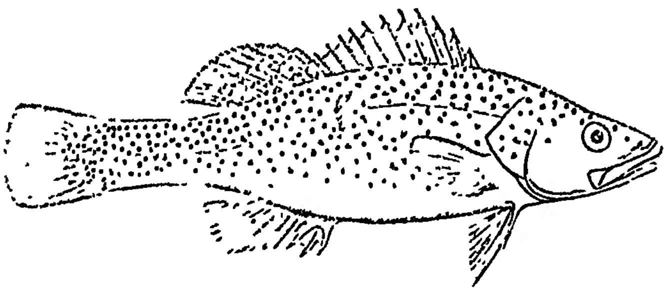
The deaths from foot-and-mouth disease vary in number at different outbreaks, and are much less than in the invasions of steppe murrain and lung-plague. The most serious feature of this murrain is its affecting a large percentage (frequently nine-tenths) of the ruminants and pigs on a farm or in a district. In 1839, in a district in Wurtemberg comprising about 8 square miles and containing 11,000 head of cattle, only 1300 or 12 per cent. escaped; in the arrondissement of Mulhausen, Alsace, containing 32,000 animals, in 1862-3-4 only about 4000, or one in eight, were not attacked; in the department of the Nord in 1839 of 277,000 cattle 120,000 were affected, more than one-half of the sheep, and one-fifth of the pigs. In Baden in 1864 of 607,825 cattle 139,995 were infected. It is scarcely possible to arrive at anything like a correct estimate of the number of cattle affected during any particular outbreak in Britain. Perhaps it would not be an exaggeration to assert that 150,000 or 200,000 suffered from the disease in 1872, and from 1839 up to 1874 it was estimated that the money loss it caused the country was £13,000,000, but this is probably far below the mark. It has been calculated that the loss experienced from an outbreak in Baden in 1869 was no less than £103,000, and for the southern states of Germany £833,000. France is supposed to have lost from this disease, among cattle only, in twenty years £4,000,000.

When it is considered how rapidly animals lose condition, especially fat stock; what losses occur when it appears among milch cows and those in calf, or amongst oxen used for draught, and among sheep, pigs, and poultry; what embarrassment it may occasion to agriculture and the cattle and milk trade, not to speak of the expense of curative measures,—it will be seen what a serious murrain this is, even under the most favourable circumstances. It is still more so when it assumes a severe character, which it often does, and is likely to be accompanied by complications. The great rapidity with which it spreads greatly increases these losses. In a very few months it has been observed to enter the eastern frontiers and spread over a large portion of the continent of Europe, infecting Germany, Switzerland, France, Holland, and Belgium, and reaching England, always following the course of cattle traffic.

These examples and estimates afford after all only a very faint notion of the devastation, misery, embarrassment, and loss that murrains occasion, and it is this which has compelled enlightened Governments to adopt severe measures for their extinction, or at least limitation. These measures are successful in proportion as they are well devised and energetically carried out, for all the murrains or contagious diseases are perfectly amenable to control, and may even be totally suppressed by international agreement and combined action. There is reason to hope that this most desirable result will be ultimately attained, but at present it is a long way off—some infected countries, in consequence of imperfect measures or the absence of any veterinary sanitary police, proving a standing menace to others which are either free from infection, or are energetically endeavouring to get rid of it. The measures now in force may be briefly said to be interdiction of the importation of cattle from countries in which cattle-plague, foot-and-mouth disease, or contagious pleuro-pneumonia is prevalent, or compulsory slaughter at the ports of debarkation. In some of the infected countries, as in the United Kingdom, where foot-and-mouth disease and contagious pleuro-pneumonia are always more or less prevalent, infected cowsheds, farms, or districts are rigorously isolated, so far as the movement of animals from them is concerned, none being allowed to leave until the disease has been suppressed, and cattle-markets or fairs may be closed for a certain period. In contagious pleuro-pneumonia, diseased animals and those which have been in contact with them are slaughtered, and compensation allowed the owner for the latter by the local authorities, while measures of cleansing and disinfection are enforced. The movement of cattle in, into, and from the infected area is closely watched to extinguish the contagion as speedily as possible

by prohibiting communication between sick and healthy animals susceptible to the malady, and so preventing the formation of new infectious centres. Evasion or infraction of the legislative orders in force for the suppression of contagious diseases in animals is punishable by fine or imprisonment. (G. FL.)

MURRAY COD. Of the numerous freshwater Perches inhabiting the rivers and watercourses of Australia the Murray Cod (*Oligorus macquariensis*) is one of the largest, if not the largest, and the most celebrated on account of the excellent flavour of its flesh. In conferring upon the fishes of the new country familiar names, the early colonists were evidently guided by the fancied resemblance in taste or appearance to some fish of their northern home rather than by a consideration of their taxonomic affinities. These, as far as the Murray Cod is concerned, lie in the direction of the Perch and not of the Cod family. The shape of the body is that of a Perch, and the dorsal fin consists of a



Murray Cod.

spinous and rayed portion, the number of spines being eleven. The length of the spines varies with age, old individuals having shorter spines, that is, a lower dorsal fin. The form of the head and the dentition also resemble those of a Perch, but none of the bones of the head have a serrated margin. The scales are small. The colour varies in different localities; it is generally brownish, with a greenish tinge and numerous small dark green spots. As implied by the name, this fish has its headquarters in the Murray river and its tributaries, but it occurs also in the northern parts of New South Wales. It is the most important food fish of these rivers, and is said to attain to a length of more than 3 feet, and to a weight of 120 lb.

MURRAY RIVER, the largest river in Australia, rises in the Australian Alps about 36° 40′ S. lat. and 147° E. long., and, flowing north-westwards, skirts the borders of New South Wales and Victoria until it passes into South Australia, shortly after which it bends southward into Lake Alexandrina, a shallow lagoon, whence it makes its ... opening at ... s source, the ... above it to ... of its course ... ner on it in ... to become ... ouches into ... breadth in ... 16; and it ... In 1836 the discovery was made by Major Mitchell that the Darling flowed into the Murray. (See AUSTRALIA, vol. iii. pp. 105, 107.)

MURRAY, or MORAY, JAMES STUART, SECOND EARL OF (1533-1570), regent of Scotland, was the illegitimate son of James V. by Margaret Erskine, daughter of the fourth Lord Erskine. While only in his fifth year he was appointed prior of the abbey of St Andrews in order that James V. might obtain possession of its funds. Under the tutorship of George Buchanan his intellectual training was carefully attended to, and as early as his fifteenth year he gave evidence of rare courage and decision by an impetuous attack on an English force which had made a descent on the Fife coast, and which he routed with great slaughter. In addition to the priory of St Andrews, he subsequently received those also of Pittenweem and of Mascon (France), but on reaching manhood he manifested no vocation for monasticism. The discourses of Knox, which he heard at Calder, won his high approval, and shortly after the return of the Reformer in 1559 Murray left the party of the queen-regent and joined the lords of the congregation, who resolved to adopt the bold measure of forcibly abolishing the Popish service. After the return of Queen Mary in 1561 he became her chief adviser, and his cautious firmness was for a time effectual in inducing her to adopt a policy of moderation and tolerance towards the Reformers. In 1562 he was created earl of Mar, and soon after married Lady Agnes Keith, daughter of the earl marischal. The earldom of Mar being claimed by Lord Erskine, he resigned the title and property and was created earl of Murray. After the defeat of Lord Huntly, leader of the Catholic party, who died soon afterwards, the policy of Murray met for a time with no obstacle or hindrance, but he awakened the displeasure of the queen by his efforts in behalf of Knox when accused of high treason, and, as he was also strongly opposed to her marriage with Darnley, he was after that event declared an outlaw and compelled to take refuge in England. Returning after the death of Rizzio, he found the sentiments of the queen towards him very greatly altered, and received a full pardon. On the abdication of Queen Mary at Lochleven he was appointed regent. The position was full of temptation and difficulty, but his conspicuous integrity and moderation, joined to unflinching courage and the utmost readiness of resource, proved to be adequate to what the circumstances demanded. When Mary made her escape from Lochleven, he occupied her attention with pretended negotiations until he had gathered his adherents in sufficient force, when he completely defeated her at Langside (13th May 1568) and compelled her to flee to England. Immediately afterwards he frustrated an attempt at insurrection by the duke of Chatelherault, whom he confined in the castle of Edinburgh. The disappointed partisans of the queen resolved to have revenge, and one of their number, Hamilton of Bothwellhaugh, shot him through the body at Linlithgow, 21st January 1570. The wound proved fatal, and he died the same evening.

MURRAY, JOHN, M.D. (1778-1820), lecturer on chemistry and materia medica, was born in Edinburgh in 1778 and died in 1820. He was a clear and popular lecturer, and his books well represent the chemistry of the time, but he will be chiefly remembered on account of his opposition to Davy's theory of chlorine. In support of the old view that chlorine is a compound of oxygen and anhydrous muriatic acid, he attempted to prove experimentally that muriatic gas contains combined water, and that chlorine contains oxygen. Dr John ... conclusively proved that Murray's experime ... curate, and that all the phenomena ca ... explained with...

anhydrous muriatic acid or the compound nature of the apparently elementary chlorine. It is interesting to note that it was in the course of the experiments made with the view of disproving Murray's conclusions that Davy discovered phosgen, the compound of carbonic oxide and chlorine.

Murray wrote *Elements of Chemistry*, 2 vols. 8vo, Edinburgh, 1801 (fourth edition, 1816); *Elements of Materia Medica and Pharmacy*, 2 vols. 8vo, 1804 (new edition, 1810); *A System of Chemistry*, 4 vols. 8vo, 1806 (fourth edition, 1818); and numerous papers in the *Transactions of the Royal Society of Edinburgh* and *Nicholson's Journal*.

MURRAY, SIR ROBERT (c. 1600-1673), one of the founders of the Royal Society, was the son of Sir Robert Murray of Craigie, Ayrshire, and was born about the beginning of the 17th century. In early life he served for some years in the French army, and, winning the favour of Richelieu, he rose to the rank of colonel. On the outbreak of the civil war he returned to Scotland and was energetic in collecting recruits for the royal cause. The triumph of Cromwell compelled him for a time to return to France, but he took an active part in the Scottish insurrection in favour of Charles II. in 1650, and was named lord justice clerk and a privy councillor. These appointments, which on account of the overthrow of the royal cause proved to be at the time only nominal, were confirmed at the Restoration in 1660. Soon after this event Sir Robert Murray began to take a prominent part in the deliberations of a club instituted in London for the discussion of natural science, or, as it was then called, the "new philosophy." When it was proposed to obtain a charter for the society he undertook to interest the king in the matter, the result being that on 15th July 1662 the club was incorporated by charter under the designation of the Royal Society. Sir Robert Murray was its first president, and during the remainder of his life exerted himself with great zeal and ability to extend its influence. He died in June 1673.

MURREE, or MARRI, a sanatorium and hill station in the Ráwal Pindi district, Punjab, is situated in 33° 54′ N. lat. and 73° 26′ E. long. It forms the great northern sanatorium for the Punjab, and is the ordinary summer resort of the local Government. The houses crown the summit and sides of an irregular ridge of the Murree hills, 7507 feet above sea-level, and command a magnificent view. The climate is admirably adapted to the constitution of Europeans; the lowest recorded temperature is 21° Fahr., the highest 96°. The resident population in 1868 was 2346; but in the height of the season it probably amounts to 12,000 or 14,000, numbers of visitors being attracted from Lahore, Ráwal Pindi, Peshāwar, and the plains generally.

MURSHIDÁBÁD, or MOORSHEDABAD, a district in the lieutenant-governorship of Bengal, lying between 23° 43′ and 24° 52′ N. lat. and 87° 43′ and 88° 47′ E. long., is bounded along its whole frontier from the extreme N. to the S.E. by the Ganges, separating it from the Nadiyá and Rájsháhí districts; on the S. by Nadiyá and Bardwán—the Jalangi river marking its boundary for a considerable distance; and on the E. by Bírbhúm and the Santál Parganás district. The area is 2141 square miles. The district is divided into two nearly equal portions by the Bhágirathi, the ancient channel of the Ganges, which flows due north and south. The tract to the west, known as the Rárh, consists of hard clay and nodular limestone. The general level is high, but interspersed with *bíls* or broad marshes and seamed by hill torrents The Bágri or eastern half differs in no respect from the ordinary alluvial plains of eastern Bengal. There are few permanent swamps; but the whole country is low-lying, and liable to annual inundation. In the north-west are a few small detached hillocks, said to be of basaltic formation. The river system is constituted by the Ganges or Padma, and its offshoots and tributaries the Bhágirathi, Bhairab, Siálmári, Jalangi, and Singá,—the first mentioned being by far the most important river within Murshidábád, though only navigable during half the year. It is embanked along the entire length of its left bank. There are no canals in the district.

The census of 1881 returned the population of the district at 1,226,790 (males 586,483, females 640,307),—Hindus numbering 634,796, Mohammedans 589,957, native Christians 250, and aborigines 836. The population comprises Bengalis of the delta, hill tribes from Chutiá Nágpur, and the peculiar Hindu castes of Behar, while the presence of the court has introduced Rájputs from the north-west for railway service or trade, Afgháns and Persians from beyond the frontier, and a bodyguard of Habshis from the east coast of Africa. The six following towns contained in 1872 a population exceeding 5000,—Murshidábád, 46,182; Barhampur, 27,210; Kandi, 12,016; Jangipur, 11,361; Beldanga, 6037; and Margrám, 5766. Other places of some importance are the river marts of Azímganj and Jiáganj, situated opposite each other on the Bhágirathi, Bhagwangola and Dhulian on the Ganges, and the railway stations of Murarai and Nalháti. Sites of historical interest include the now deserted Kásímbazar, Badrihat, Rángámáti, and the battlefield of Gheria.

Rice constitutes the staple crop, the *áman* or winter rice being prevalent in the western half of the district, and the *aus* or early rice in the eastern. A second or cold weather crop of wheat, barley, and many varieties of oil-seeds and pulses is also grown in this latter tract, jute is but little grown, and the cultivation of indigo and of mulberry for silkworms is on the decline. There is little that is peculiar in the land tenures of the district beyond the *ramnás* or deer parks, held revenue-free by the nawáb, and the cultivating tenure known as *ut-bandi*, according to which the peasant pays rent, not for his entire holding, but only for the land actually cultivated, the amount being determined by the nature of the crops grown, and being paid in kind. Silk is still manufactured, but the industry is rapidly losing its importance. At Murshidábád city and at Barhampur there are special industries of ivory-carving, bell-metal work, and gold and silver embroidery. The district is favourably situated for trade, both by river and rail. In 1876-77 the exports amounted to £1,020,124; the imports to £739,906. The principal exports consisted of rice, gram and pulses, wheat, silk, and indigo; the principal imports of European piece goods, salt, and raw cotton.

In 1881-82 the net revenue amounted to 1,803,828 rupees, of which 1,298,735 were derived from the land-tax Education in 1876 was afforded by 506 schools, attended by 14,664 pupils The special educational institutions are the Barhampur College, founded in 1853; the Nizámat College, limited to the education of the relatives of the nawáb; and the Nizámat free school in Murshidábád city. The climate does not differ from that common to Lower Bengal, except that it experiences to some extent the burning winds of Central India during the hot season. The average annual temperature is 78°·6 Fahr. In 1880-81 it was 59·82, and in 1881-82 it was 47·76. The average annual rainfall is 54·30 inches The district has a low standard of health. The stagnant pools formed by the Bhágirathi during the dry season constitute a perennial source of malaria, and cholera is rarely absent from the city and suburbs. Elephantiasis and hydrocele are also endemic.

The history of the district centres round the city of Murshidábád, the latest Mohammedan capital of Bengal. In 1704 the nawáb Murshid Kulia Khan changed the seat of government to the little town of Maksudábád, but when Alí Vardí Khán won the throne by conquest in 1740 he also adopted Murshidábád as his capital. The great family of Jagat Seth maintained their position as state bankers at Murshidábád from generation to generation Even after the conquest of Bengal by the British, Murshidábád remained for some time the seat of administration Warren Hastings removed the supreme civil and criminal courts to Calcutta in 1772, but in 1775 the latter court was brought back to Murshidábád again In 1790, under Lord Cornwallis, both the entire revenue and judicial staffs were ultimately fixed at Calcutta

MURSHIDÁBÁD, principal city of the above district, is situated on the left bank of the Bhágirathi river, in 24° 11′ N. lat. and 88° 18′ E. long. Its importance has entirely departed since it ceased to be the capital of Bengal, and its population has steadily diminished In 1872 the population was 46,182 (Hindus 27,211, Mohammedans 18,824, Christians 38, "others" 109). It is still a great centre of trade and manufacture, and the Jain merchants of Murshidábád still rank as the wealthiest of their class in Bengal. Their dealings in gold and silver bullion are especially large, and some of their number almost monopolize the local traffic on the Brahmaputra as

far as the north-east frontier of Assam. The principal industries of the city are those fostered by the luxury of the native court. Carving in ivory, conducted with much skill and finish, is an old speciality of the city. The principal building is the new palace of the nawáb názím, a large and imposing pile of buildings on the banks of the river, and nearly in the centre of the city.

MURZUK. See FEZZAN, vol. ix. p. 130.

MUS, the name of a family of the plebeian gens of the Decii. Two members of the family, a father and a son, crowned distinguished careers in the service of Rome by a singular act of self-devotion. The father, Publius Decius Mus, won his first laurels in the Samnite war, when in 343 B.C., while serving as tribune of the soldiers, he rescued the Roman main army from an apparently hopeless position. In 340 B.C. he was consul, and had, with his colleague Manlius Torquatus, the command in the Latin war. A decisive battle took place under Mt. Vesuvius; the Romans wavered, and Decius, repeating after the chief pontiff a solemn formula by which he devoted "the legions and auxiliaries of the enemy along with himself to the Dii Manes and the earth-goddess," dashed into the ranks of the Latins and met a death which was followed by a crushing defeat of the enemy (Livy, viii. 9).

The son, who was also called Publius, was consul for the fourth time in 295 B.C., and devoted himself after the pattern of his father in the battle of Sentinum, when the left wing which he commanded was shaken by the Gauls (Livy, x. 28). The story of the elder Decius is regarded by Mommsen as an unhistorical "doublette" of what is related on better authority of the son.

MUSÆUS is the name of three Greek poets. The first is an almost fabulous personage, who is said to have flourished in Attica, and to have been buried on the Museum Hill in Athens. The mystic and oracular verses and usages of Attica, and especially of Eleusis, attach themselves to his name, and when this representative character is deducted nothing of his individuality remains.

The second Musæus was an Ephesian who was attached to the court of the Pergamenian kings.

The third is of uncertain date, but probably belongs to the 5th century A.D., as the structure of his hexameters is evidently modelled after the canons of Nonnus. The poem in 340 lines which he wrote on the story of Hero and Leander is by far the most beautiful Greek poem of the age. He conveys the pathetic tale of love and death by selecting a few striking situations; he describes each of them in a telling manner, with no attempt to represent ethical character or earnest thought, but with a good eye to the situation, the dramatic and rhetorical effect. The work shows the influence of the schools of rhetoric, and is evidently the forerunner of the love romances of the Byzantine period.

MUSÄUS, J. K. A. (1735-1787), a German author. He studied theology at Jena, his birthplace, and would have become the pastor of a parish but for the resistance of some peasants, who objected that he had been known to dance. In 1760 to 1762 he published in three volumes his first work, *Grandison der Zweite*, afterwards (in 1781-82) rewritten and issued with a new title, *Der deutsche Grandison*. The object of this book was to show the comic aspects of Richardson's hero, who had many sentimental admirers in Germany. In 1763 Musäus was made tutor of the court pages at Weimar, and in 1770 he became a professor at the Weimar gymnasium. His second book—*Physiognomische Reisen*—did not appear until 1778-79. It was directed against Lavater, and attracted much favourable attention. In [illegible]2 to 1786 he published his most [illegible] *[illegible]chen der Deutschen*. Even in this [illegible] of which Musäus collected [illegible] not refrain from expressing the satirical tone which had marked his previous writings. The stories, therefore, lack the unconscious simplicity which characterizes genuine folk-lore. Still, they are very brightly written, and retain at the present day some of their original popularity. In 1785 was issued *Freund Hein's Erscheinungen in Holbein's Manier* by J. R. Schellenberg, with explanations in prose and verse by Musäus. A collection of stories entitled *Straussfedern*, of which a volume appeared in 1787, Musäus was prevented from completing by his death, which occurred on the 28th of October 1787. After his death appeared his *Moralische Kinderklapper* and *Nachgelassene Schriften*, the latter edited by his friend and relative Kotzebue. Musäus was a man of cheerful and genial temperament, and this dominant characteristic is reproduced in his writings, in which, although satirical, he is never morose. His style is animated, light, and graceful.

See Müller, *Johann Karl August Musäus* (1867).

MUSCAT, or more correctly MASḲAT, the chief town of 'Omán in Arabia, lies upon the sea-coast in 23° 40′ N. lat. and 58° 25′ E. long., at the extremity of a small cove in the gorges of a great pass leading inland through dark mountain walls, scorched with the sun and utterly without vegetation, which rise almost right out of the sea to a height of from 300 to 500 feet on both sides of the cove. The town itself is built on a sloping shore, which affords space for some scanty patches of cultivated ground beyond the gates. The interior aspect of Muscat does not correspond to the extremely striking appearance it presents when approached from the sea. The ruins of the Portuguese cathedral, the palace, the minarets, and a few other great buildings tower over narrow crowded streets and filthy bazaars, long rows of good houses now falling into decay, and a mass of mean dwellings of sun-dried brick or wretched huts of palm branches. The whole aspect was described by Palgrave in 1863 as that of decay, but the town was still populous, and Palgrave estimated the inhabitants at 40,000, exclusive of the suburbs. Indeed the excellent harbour so admirably situated for the Indian and Persian Gulf trade, the strength of the whole position, which is defended by forts on the encircling rocks and might easily be rendered impregnable, together with the command of the passes to the fertile lands beyond, make it naturally the most important point on all the coast. The inhabitants and government are favourably spoken of; the population is a mixture of the most varied nationalities, including very many Indians; but good order is maintained and equal justice administered to all creeds. The Mohammedan citizens have a considerable strain of African blood, the slave trade having been very active before the convention of England with Zanzibar. The climate is not good; the summer heat in so confined a situation is very great, and epidemic fevers are common. The exports (salt, dates, fish, cotton, pearls, mother-of-pearl, &c.) and imports (rice, coffee, sugar, piece goods, &c.) are very considerable, amounting perhaps together to a million sterling per annum.

Round the cape which forms the north-west limit of the cove lies the prosperous and well-built town of Matrah, with 20,000 to 25,000 inhabitants, and a considerable production of 'Omán stuffs. It may be regarded as a suburb of Muscat, though the land road over the cape is so rough that communication between the towns is conducted chiefly by boats.

Muscat is an ancient place, perhaps identical with the Moscha of the *Periplus*. In the 9th century of the Christian era ships trading from Síráf to China took in water at Muscat from the well which still supplies the town; but the place was then quite small, Ṣohár, farther up the gulf, being the chief place on the 'Omán coast. The importance of Muscat appears to date from the Portuguese occupation (1508-1658). In the first half of last century the contests of the rival imáms of 'Omán, Saif and Ibn Murshid, placed the town in the hands of the Persians, who were expelled about 1749 by Aḥmed b. Sa'id. The residence of this prince was at Rustáḳ, but

his grandson Sa'id made Muscat the capital, and cultivated the friendship and commerce of the English in Bombay and of the United States, to the great advantage of the city. Under Sa'id's successor Thuaini family feuds and the intervention of the Wahhâbites impaired the prosperity of the state. Thuainí was murdered in 1867, but after some further troubles his son Turkí was established on the throne by the aid of British influence.

MUSCATINE, a city of the United States, the county seat of Muscatine county, Iowa, is built on a rocky bluff on the west bank of the Mississippi, at the apex of what is known as the Great Bend. It carries on a large business in lumber, milling, canning fruits and vegetables, &c. Settled in 1836, and incorporated as a city in 1853, it increased its population from 5324 in 1860 to 8295 in 1880.

MUSCINEÆ. The Muscineæ are a highly interesting class of plants on account of the important part they play in the economy of nature, and also from the remarkable conditions of their development and formation. In many parts of the world it is principally the mossy covering of forests which, by collecting the rainfall like a sponge, prevents the pouring down from mountains of violent and excessive torrents of water, while the Bog-moss (*Sphagnum*) plays an important part in the formation of peat; and many other Mosses which grow on rocks produce by the decay of their dead parts a thin layer of mould (humus) in which the seeds of higher plants are able to take root. The importance, however, of Mosses in a morphological point of view proceeds from their position in the botanical system. The Muscineæ immediately follow the first division of the vegetable kingdom, the Thallophytes, under which are included the Algæ and Fungi, because their vegetative body is a "thallus,"—that is to say, is not divided into stem and leaf like that of higher plants, nor are they possessed of roots like those observed in higher plants (Ferns, Conifers, Monocotyledons, Dicotyledons, &c.). Their anatomical structure is also very simple, the individual essential tissue-elements being but little differentiated from each other.

The Muscineæ agree in many of their conditions with the Thallophytes, in others again with the next higher division, the vascular Cryptogams (Pteridophytes), to which the Ferns, Equisetums, and Lycopodiums belong. In many Muscineæ of the division of Liverworts (*Hepaticæ*) the vegetative body has still the form of a thallus (fig. 1), which is ribbon-shaped and grows in close contact with the substratum. There are, however, several gradual stages of transition from this ribbon-shaped thallus to a leaved stem, such as many Liverworts (*Hepaticæ*) and all Leaf-mosses (*Musci frondosi*) possess. Yet the structure of the leaves and of the stem, even in the latter, is very simple. The leaves present for the most part a cell-surface of one layer. and that (if we leave out of sight those in the middle part of the leaf, which in Leaf-mosses form the "mid-rib") is ordinarily composed of cells of uniform character. There is thus no epidermis as in higher plants, and the leaf itself attains but very trifling dimensions. The stem is also of simple structure; it possesses no "vascular bundles," but consists only of simple cells, among which there is no differentiation, except that those which lie outside often have thicker walls, and thus form a firmer rind-layer, while the interior ones are more elongated and serve for the storage and transmission of the plastic substances (albumen, hydrocarbons, &c.). The roots also by which the stems are attached to the ground are of very simple organization. They are either hair-like tubules as in many Liverworts, or rows of cells as in the Leaf-mosses. To distinguish them from the roots of higher plants they have been termed "rhizoids." In many cases the vegetative body scarcely attains one twenty-fifth of an inch in length, in others, however, it rises into a much-branched form of from about 4 to about 12 inches or more. The duration of its life reaches in some small forms (*Ephemerum*, *Phascum*, &c.) only a few weeks or months; in most cases, however, it is virtually unlimited, since the vegetative body continues to grow at its point while the older parts below are dying away. From this cause too the branches are isolated from each other, and become independent plants. In a peat-moor, for instance, the Bog-moss plants on the upper surface are the points and branches of the very same plants whose under-parts have long ago died away, and have principally contributed to the formation of the peat. This isolation of the branches through the dying away of the older parts which keep them together is at the same time a means of multiplication. Mosses also possess many other arrangements for asexual multiplication, as through gemmæ, "innovations," &c. In the Liverworts, for instance, almost every cell is capable of giving origin to a new plant.

The most extensive propagation, however, of the Mosses is that by means of spores, small roundish cells which are formed in a peculiar capsule, the *sporogonium*. The formation of these sporogonia is especially characteristic of the Muscineæ. They originate, as a consequence of fertilization, from a cell—the ovum-cell—which is generated in the female sexual organ, the *archegonium*. These archegonia (fig. 6) have, when ready for fertilization, the form of a flask. They consist of an inferior and somewhat swollen portion, which contains the ovum-cell, and of a superior portion drawn out to some length, the neck. The neck forms a canal through which the male fertilizing bodies, the spermatozoids (fig. 5, *D*), enter to blend with the ovum-cell. In the immature condition the archegonium is closed, its neck portion is filled up with a string of cells and covered at the top by a layer of cells which closes it like a lid (fig. 6). At a later period, however, the membranes of the string of cells which fills up the neck (the canal-cells of the neck) are converted into a jelly, which on contact with water swells up greatly, forces open the apex of the neck portion, and thus presents an open access to the ovum-cell. The mucilage which arises from the swelling up of the canal-cells of the neck is also so far of importance with regard to fertilization that by it the freely-moving male fertilizing bodies are stopped when they reach the neck of the archegonium. The male fertilizing bodies are here, as in many Algæ, in the vascular Cryptogams, and in most animals, termed *spermatozoids*. They are spirally-coiled filaments, thickened at the posterior extremity, finely pointed at the anterior, and bearing at this thin end two long fine cilia by means of which they can move in water. The spermatozoids are formed in the male sexual organs, the *antheridia* (fig. 5, *C*), which are bodies with long or short stalks, and of spherical, oval, or club-shaped form, surrounded by a wall-stratum consisting of a simple layer of cells, and which possess in their interior a tissue formed of numerous small cells, in each of which one spermatozoid takes its origin. When the wall-layer of the antheridium is torn asunder the spermatozoids are set free at its apex, and move in water by means of their cilia, like Infusoria. Thus water is always necessary to fertilization; it is only in water that the neck of the archegonium opens, and that the spermatozoids can move. Since either the Mosses grow in moist localities, or those which spring up in dry situations always form little turfs so as to suck up every drop of rain like a sponge, their fertilization is always secured, provided the organs of both sexes are present.

Even before the opening of the archegonium-case the oosphere has formed itself in the inferior portion of the archegonium. Originally in this inferior ventricose portion of the archegonium is a large cell, the *central cell*

(fig. 6). From this a small cell is severed in an upward direction, which perishes at a later period, and is called the *ventral canal-cell* (fig. 6, *b*), while the inferior cell becomes round and forms itself into the oosphere. When ready for fertilization the ovum-cell is a spherical portion of protoplasm with a cell-nucleus (fig. 6, *e*). Fertilization follows on the blending of one or perhaps several spermatozoids with the oosphere. The first result of fertilization is that the oosphere becomes surrounded by a membrane of cellulose, and then grows very notably, while correspondingly with this growth it becomes divided by cell-walls, and thus becomes a cellular body. From the fertilized oosphere proceeds the moss-fruit, the sporogonium. The embryo which has proceeded from the fertilized oosphere lives at the expense of the vegetative body on which the archegonium is situated, like a parasite on the plant that nourishes it. The ventral portion of the archegonium grows along with the embryo. In *Riccia*, the lowest form of one subdivision of the Liverworts, the sporogonium remains even during the whole lifetime of the plant shut up within the ventral portion of the archegonium, and the spores formed in the sporogonium are not set free until that part of the plant on which the archegonium is situated withers away. In most other Liverworts also the sporogonium attains almost its entire development within the ventral portion of the archegonium, which grows contemporaneously with it, and it is not until the spores are mature that the stalk of the sporogonium extends itself considerably (fig. 3, (1), *A*); then the ventral portion of the archegonium springs in pieces and the spore-capsule issues forth and scatters its spores,—an occurrence which is completed within a few days. The ventral portion of the archegonium, which increases considerably after fertilization and which surrounds the embryo like a sheath, is termed *calyptra*. In the case of the Liverworts this calyptra is burst open by the sporogonium; in the Mosses, however, the elongated fusiform-embryo tears away the calyptra at its base and raises it up like a cap on its apex, and it is then found situated on the extremity of the sporogonium. In many Leaf-mosses (*Polytrichum*, *Hypnum crista castrensis*) the sporogonium requires more than a year for its development.

The function of the sporogonium is the production of spores. The simplest mode in which this takes place is seen in the species *Riccia*. Here the sporogonium is a spherical cell-body, consisting of a wall-layer and an interior tissue. The cells of this latter are called the *mother-cells* of the spores, because each of them by division forms four spores. In the species, however, which stand higher we can distinguish in the sporogonium a foot, which frequently penetrates into the tissue of the vegetative body, and in many Liverworts and almost all Mosses prolongs itself into a stalk supporting the capsule in which the spores are formed (figs. 3, 7, 8). In the case of most Liverworts we find in this capsule, besides the spores, also a number of cells which do not become spores. These either act as "nutrient cells" to the spore-forming cells, which gradually consume the matters stored up in them (*Riella*), or they form themselves into fusiform-cells with spiral thickenings of parts of the wall—the so-called *elaters*, which play a part in the dispersion of the spores. The sporogonia of Mosses do not possess elaters. They are rather complex structures, and attain a higher anatomical differentiation than the moss-stem itself. For example, at certain points in their epidermis they possess openings (*stomata*), which are entirely absent on the stem. In order to ensure the dispersion of the spores, special arrangements are found in the sporogonia of Mosses.

The course of development of the Muscineæ divides itself into two sharply-defined stages. The vegetative body, whether it be only a thallus as in many Liverworts, or a leafy stem, produces the sexual organs, the antheridia and the archegonia. From the fertilized oosphere of the archegonium arises a special structure, the sporogonium, which does not nourish itself independently, but lives like a parasite upon the moss-plant, and produces the spores only in a sexual way. The two stages—on the one hand the moss-plants that bear sexual organs, and on the other the sporogonium developed as the result of fertilization—are termed *generations*; accordingly in the Muscineæ the course of development consists in a regular alternation of these two stages—in an *alternation of generations*. The one generation possesses sexual organs, and is thus the sexual one. The other generation, the result of fertilization, possesses no sexual organs and is asexual, but produces the spores. Such alternation of generations is exhibited still more strikingly in Ferns. In this case, however, it is the proper leafy fern-plant which is the asexual generation, producing spores, but possessing no sexual organs. It arises out of a fertilized oosphere, and thus corresponds to the sporogonium of the Muscineæ. The sexual generation of the Ferns is a small and insignificant expansion, the prothallium, which bears antheridia and archegonia, and thus corresponds to the sexual generation of the Muscineæ, which is here represented by the proper moss-plant. The vegetative body of the Mosses which bears the sexual organs is not, however, the immediate product of the germination of the spore, from which there is produced in the first place a simple structure, a *pro-embryo* (specially developed in the Mosses proper, where it is termed "protonema," and where it assumes the appearance of a much-branched filamentous confervaceous Alga, fig. 15); it is from this pro-embryo that the leafy stems arise as lateral buds.

From a systematic point of view the Muscineæ are divided into two sections—Liverworts (*Hepaticæ*) and Mosses (*Musci frondosi*). The two sections are closely related to each other, but in external characters they are separated by rather sharp boundary lines.

I. Liverworts (*Hepaticæ*).

Liverworts stand below the Mosses proper in regard to the number both of species and of individuals. They are also of much more limited occurrence, for they are found, for the most part, only in damp and shady localities, and seldom occupy any large extent of ground. The most extensive growths are those of many *Marchantiaceæ*—as, for example, *Fegatella conica*, which often forms a continuous covering on moist stones, walls, &c.

(1) *The Organs of Vegetation.*—With a few exceptions, the vegetative body is closely united to the substratum on which it grows, and fastened to it by clasping-roots (rhizoids) composed of a single cell. The side turned towards the substratum is of different structure from the upper or dorsal side. The Liverworts thus belong, with the exception of two species, to the class of *dorsi-ventral* plants, or those possessing two sides of different structure, a dorsal side and a ventral side, as in vertebrate animals.

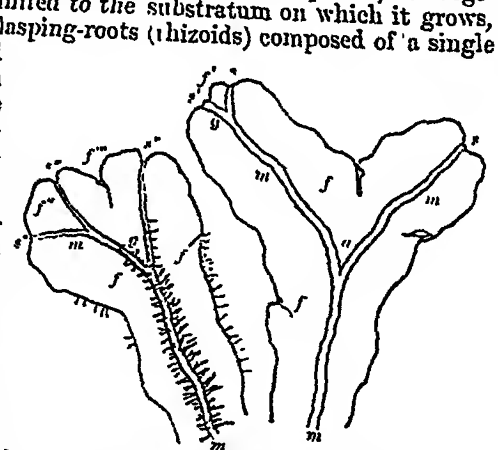


Fig. 1.—*Metzgeria furcata* (magnified about 10 diameters). The anterior portion of a thallus, seen on the right hand from above and on the left hand from below. *m*, mid-rib; *s*, *s'*, *s''*, the growing points; *f*, *f*, the wing-like expanded portion of the thallus, composed of a single layer of cells; *f'*, *f''*, *f'''*, its development by ramification. (After Sachs.)

The vegetative body of the Liverworts is either a thallus or a leafy plant; and we have consequently to distinguish between *thallose* and *foliose* Liverworts. The latter have already been termed *Hepaticæ frondosæ*. There occur, however, transitional

forms between these two. Fig. 1 represents an example of a thallose Liverwort, showing the anterior portion of a plant of *Metzgeria furcata*. On the right hand is shown the upper, on the left the under side. The vegetative body is a ribbon-shaped thallus, on the under side of which the clasping-roots (rhizoids) spring out of the mid-rib. Here the mid-rib is sharply separated from the side portions, but in other cases (as *Aneura* and *Pellia*) it passes into them by a very gradual transition. In front, in an indentation of the growing point (*s*), are found the only organs which are formed upon it. These are hairs secreting mucilage (papillæ), and which stand on the under side. The mucilage which they secrete is probably intended for the purpose of protecting the vegetative point against the effects of drought.

A peculiar exception appears in the growth of the genus *Riella* (fig. 2). In this case a membranous wing, about one-fifth of an inch in width, of the finest green and of extreme delicacy, turns regularly on a central rib or axis, so as to form with the axis a sort of screw or winding staircase, having the form of an inverted cone with the apex downwards. The length of the whole plant of *Riella helicophylla* is about 2 inches. This plant, which is decidedly one of the most remarkable forms in the vegetable kingdom, grows upright in water, and was discovered in Algiers. At its lower end it is attached to the ground by clasping-roots. This is the only thallose Liverwort that grows upright, and also one of the few that grow in water. There are likewise two species of *Riccia* which swim in water—*Riccia natans* and *Riccia fluitans*; but these also possess forms which live on land, and it is these forms which attain to the formation of sporogonia. It follows hence that these plants also were originally in every case land plants. A few others too, such as *Pellia epiphylla* and *Marchantia polymorpha*, have the power of vegetating in water, but this happens only exceptionally, and the plants are then sterile.

FIG. 2.—Plant of *Riella helicophylla*, from Algiers.

Returning to the thallose Liverworts that live on land, we have to remark that the differentiation of their tissues is a very simple one. The cells of the thallus, so far as they are not employed in the formation of clasping-roots or of sexual organs, are all homogeneous. Those only of the mid-rib present a difference in *Metzgeria*, *Blyttia*, and others by their lengthened form. From this simple form has arisen a further complication in the development of the vegetative body in two different series. In the *Marchantiaceæ* the vegetative body retains the form of a thallus, but its anatomical organization is of higher structure. In the *Jungermanniaceæ* it is the external organization of the vegetative body which is the richer, and here the transition takes place in it to the foliose Liverworts, which possess a stem with leaves.

We may consider as representative of the *Marchantiaceæ* the very widely-spread *Marchantia polymorpha*. Its vegetative body is a broad ribbon-shaped thallus, which has on its under side elasping-roots (single-celled tubules, which are either simple, or have on their inner side characteristic conical or tubercular thickenings) and two rows of membranous lamellæ, the uppermost of which cover the growing point and form a protection to it. (See the section through *Fegatella*, an allied form, fig. 3, (1), *L*.) The upper surface presents a division into small rhomboidal spaces (areolæ), and in the middle of each space is an opening, the *stoma* or breathing hole. A section through the thallus shows a strongly-marked epidermis broken through at definite spots by the stomata or breathing holes, which, however, in this case have a very different structure from that presented in the higher plants. In *Marchantia* (fig. 3, (5), *Sp*) they are of barrel-shaped figure, and consist of several rings or tiers of cells placed over one another. Their origin may be traced in fig. 3, (3) and (4). Below the epidermis we find chambers filled with air. These, however, are not empty; from their base sprout forth cellular threads (fig. 3, (5)), the cells of which contain a large quantity of chlorophyll. It is in these that the assimilation of the carbon takes place. Those cells of the thallus which lie beneath serve only for the storing up and transmission of the materials for construction. The individual chambers are separated from each other by flat layers of cells, and on these rest the rhomboidal areolæ of the upper surface which can be seen with the naked eye. In other *Marchantieæ* the stomata are of a different structure. In *Fegatella*, for example, they are not barrel-shaped, but are bounded by several concentric circles of cells, which all lie on the upper surface of the thallus. Early stages of these are represented in fig. 3, (2). The way in which the air-chambers and stomata attain their condition is very remarkable. Small depressions in the cell-layer of the upper surface are formed in large numbers behind the growing point (fig. 3, (1), *U*). These widen considerably, and become, as it were, roofed over by the neighbouring parts, so that an epidermis (fig. 3, (1), *E*) grows in this manner over the hollows from the bottom of which at a later period the green cellular threads sprout forth. The strings of mucilage-cells which are found in the tissue of *Fegatella*, the brown threads which appear in that of *Preissia*, and the cells filled with a brown oily secretion which are found in *Marchantia* and other species must also be mentioned.

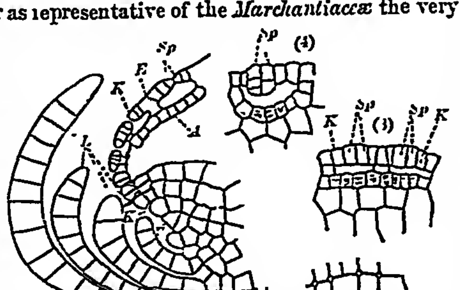

FIG. 3.—(1) Longitudinal section through the growing-point (apex) of *Fegatella conica*. On the upper side of the thallus are formed the air-chambers, as depressions in the upper surface *K*. On the under side of the thallus are formed membranous scales *L*, which always proceed from *one* cell. (2) Surface-view of a young portion of the thallus; the stomata appear as gaps in the epidermis. They are surrounded by a few concentric cells, of which the first are represented. (3), (4), (5) *Marchantia polymorpha*; development of the air-chambers and stomata. In (5) a number of cell-threads containing chlorophyll are seen sprouting from the bottom of the air-chamber.

The second series, which comes next to the simple thallose forms, is that of the foliose or leafy *Jungermannieæ*. Forms intermediate between the thallose and the foliose are represented by the species *Blasia* and *Fossombronia*. The former, which not unfrequently grows in the damp soil of forests, possesses a flat, thallus-like stem, which bears on its longitudinal axis two rows of leaves inserted parallel to each other, and has also on the under side two rows of toothed scales, the *amphigastria*. *Fossombronia* makes a nearer approach to the proper leafy forms; it possesses two rows of leaves inserted obliquely to the longitudinal axis of the flattened stem. In the foliose *Jungermannieæ*, in the narrower sense of the term, the stalk is thin and thread-like, and bears distinctly defined leaves. In this case also—with the exception of the upright growing *Haplomitrium Hookeri*—the stem grows in close connexion with the substratum. The leaves stand in three rows: two lateral, and one ventral towards the substratum. The ventral leaves are in this case also, as in *Blasia*, termed *amphigastria* or under leaves. They are smaller than the side leaves, and are sometimes reduced to the form of mere hairs, or even are entirely wanting, as in *Jungermannia bicuspidata*, where it is only in rare exceptional cases that they appear. The leaves of Liverworts consist of a single layer of cells without any mid-rib. They are commonly bifid at the apex, but in many forms this condition is only recognizable in early development, and disappears before maturity.

In general the leaves stand so thickly that they overlap each other with their margins, and quite cover the upper surface of the stem. The way in which the leaves overlap has been employed as a systematic character. *Overshot* leaves (*folia succuba*) are those in which the anterior margin turned towards the vegetative point of the stem stands higher than the posterior one, and thus the anterior margin of each leaf overlaps the posterior margin of the leaf which stands before it, while its own posterior margin is overlapped by the anterior margin of the leaf which stands behind it. In the opposite case of *undershot* leaves (*folia incuba*), the posterior margin of the leaf is higher than its anterior margin, and the anterior margin, inclining obliquely outwards, is overlapped by the posterior margin of the leaf which comes next before it, as in fig. 4. The mode in which the leaves overlap each other depends on a difference in the relative amount of growth of the upper or dorsal and the under or ventral side respectively. If the growth of the upper side preponderates, then we have the overshot, in the opposite case the undershot mode of covering. Originally the leaves do not stand obliquely to the longitudinal axis; it is only gradually that they are shifted out of their place. The position of the leaves is explained by their origin. The apex of the stem is occupied by a cell which has the form of a three-sided pyramid with a vaulted base. The surface of one side of the pyramid is directed downwards, the two others are directed laterally. This apical cell is divided by walls which are parallel alternately to one of the side walls. Thus segments are cut off from the apical cell and lie in three rows. From each of these segments arises a leaf. The leaves are thus necessarily likewise arranged in three rows, one of which is turned towards the substratum.

The anatomical structure of the stem is also a very simple one. Its exterior cells have their walls somewhat more strongly thickened, and thus form a firmer rind-layer. We must also notice the secretion of dark-brown oily corpuscles, which undergo no further conversion, and are met with in certain leaf-cells. In the thallose

forms the ramification is of a forked character (dichotomous) (fig. 1). Frequently too, on the older portions, "adventitious" shoots

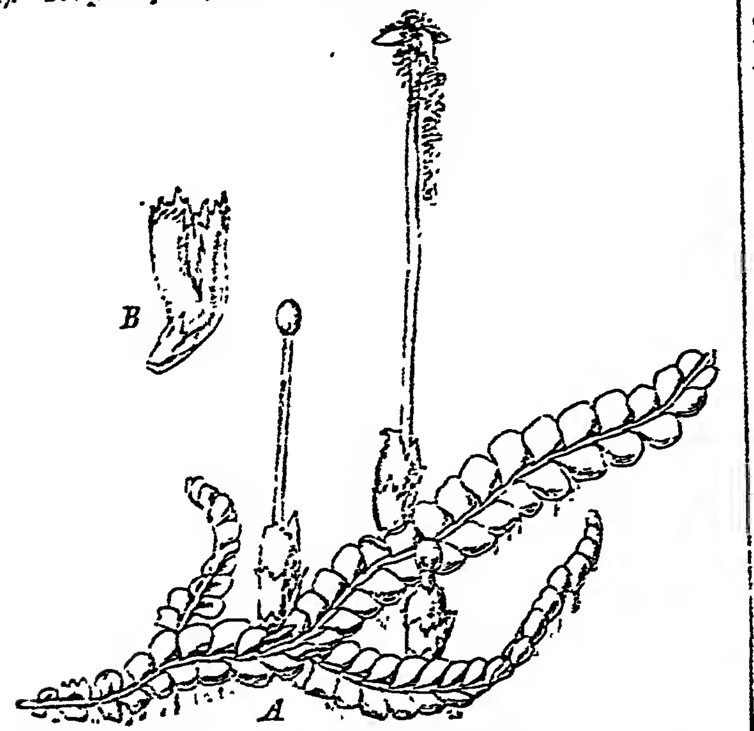

FIG. 4.—*A.* A leafy (foliose) *Jungermannia* (*Chiloscyphus polyanthos corda*) with three sporogonia; on the right above is one with the capsule open, while in the two others it is still closed. *B.* A "perianthium," with the perichætial leaves below.

are formed; they may frequently be seen to spring from the margin and the mid-rib of the thallus of *Metzgeria furcata*. The ramification of the foliose Liverworts is a very complex one, but is never of a really forked character. The branchlets commonly stand below the leaves on the sides of the stem.

The above-mentioned "adventitious" shoots serve the purpose of vegetative increase. The same end is attained by the gemmæ, which are of many different forms. In *Aneura* individual cells detach themselves from the thallus and grow up into new plants. In the *Marchantieæ* the gemmæ are formed in peculiar receptacles which stand on the upper side of the ribbon-shaped thallus. In *Marchantia polymorpha* these receptacles have the form of a basket open at the top, while in *Lunularia* the margin of the same receptacle is semicircular. The gemmæ, which are developed on the base of the receptacle, are flat upright cellular bodies, with two indentations at the sides, out of which at a later period, at the time of germination, proceed two growing points. The gemmæ, however, are of similar structure on both sides. Which side is at the time

fertilization of an archegonium, it is evident that an enormous number of them must perish.

The archegonia also proceed from one cell, through the division of which their construction is accomplished. They always take their origin from the cells of the upper surface, and the same is the case with those of *Anthoceros*, which, however, are sunk into the tissue of the thallus, so that their neck and ventral portions remain united with the tissue of the thallus and do not project freely over it.

The distribution of the organs of sex is either monœcious or

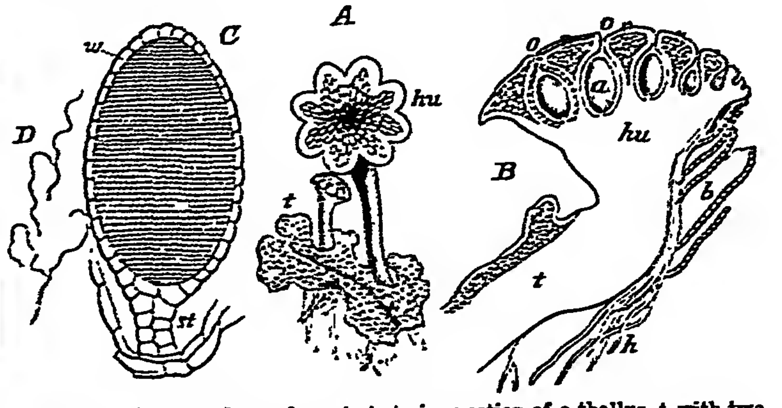

FIG. 5.—*Marchantia polymorpha.* *A.* Anterior portion of a thallus, *t*, with two erect antheridial inflorescences *hu*. *B.* Longitudinal vertical section through a young antheridial inflorescence. The antheridia are situated in depressions of the upper surface. *b*, scales; *h*, roots (rhizoids); *o*, *o*, the openings of the depressions in which the antheridia lie. *C.* A nearly mature antheridium; *st*, its stalk; *w*, the wall. *D.* Two spermatozoids, magnified 800 diameters. Each possesses two fine cilia. (After Sachs.)

diœcious. In the latter case the antheridia and archegonia are found on different individual plants, as in *Sphærocarpus terrestris*, where the male plant is smaller than the female. In the former case the antheridia and archegonia are found on the same plant. In the thallose forms they are always inserted on the dorsal side of the thallus, and commonly sunk into a cavity in it (fig. 5. *B*). In *Anthoceros* the antheridia even stand in closed cavities, which do not open till the antheridium is mature. The organs of sex stand either on ordinary branches, which at a later period vegetate and grow, or on special sexual shoots. These are of especially remarkable construction in the *Marchantieæ*, of which *Marchantia polymorpha* may serve as an example. In this species the antheridia are found on the upper side of a peltate radially-lobed disk, supported on a stalk (fig. 5, *A*). The archegonia stand on the under side of a similar receptacle. These structures may be termed "inflorescences." They are not simple branches, but systems of branches which have arisen from the repeated bifurcation of a thallus-shoot. Each indentation in the disk of the "inflorescence" corresponds to the vegetative point of a branch, and this explains the fact that the oldest antheridia are found in the centre of the disk; and from this point to the periphery, where the vegetative points are found, are successive groups of antheridia of younger growth, for the youngest organs of sex always stand next to the vegetative point of the shoot. The stalk of the inflorescence is nothing else than the inferior portion of the branch-system greatly prolonged. In the leafy *Jungermannieæ* the distribution of the organs of sex is also either monœcious or diœcious. The archegonia in this case stand either singly (*Lejeunia*, &c.) or in larger groups. The first archegonium always arises from the apical cell of the shoot connected with it, so that with it the latter closes its longitudinal growth. This circumstance has been employed in the classification of the foliose *Jungermannieæ* (with the exception of *Haplomitrium*) as *acrogynous* in contradistinction to the *anacrogynous*, in which latter the archegonia never proceed from the apex of the shoot itself.

Whilst the archegonia of the thallose forms are protected by being lodged in an excavation of the thallus, or surrounded by a luxuriant growth of its tissue, the archegonia of the foliose *Jungermannieæ* are enveloped by the leaves of the stem-bud, which on that account are termed perichætial leaves (*folia perichætialia*), or, collectively, perichætium. Between these perichætial leaves and the archegonia there grows up in most forms a second involucre, of a goblet or pitcher shape, the "perianthium" (fig. 4, *B*). It springs up in the form of a circular fence, gradually growing upwards. In many *Jungermannieæ* (*Calypogeia*) the archegonia are enclosed in a kind of sack-shaped structure, which forces its way into the ground, in which, in fact, it takes root. This "fruit-sac" in the *Jungermannieæ geocalyceæ* is the hollowed-out shoot from which the archegonia arise. Its extremity becomes thickened and forms a circular fence about the archegonia: thus there arises a structure about two twenty-fifths of an inch long, which is constantly becoming deeper, and at the bottom of which the archegonia are placed. There is always an endeavour to protect and envelop the archegonia. This is notably conspicuous in the *Marchantieæ*, where round every archegonium there grows after

fertilization a special goblet-shaped involucre, whilst every group of archegonia is also enveloped by two scales, which incline towards each other like the valves of a mussel-shell.

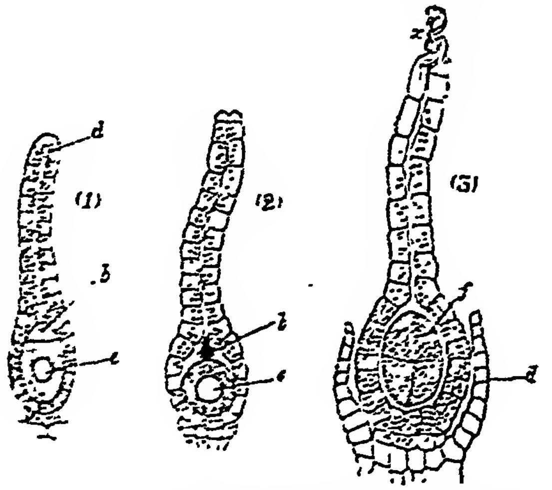

Fig. 6.—*Marchantia polymorpha.* Archegonia at different stages of development in longitudinal section. (1) An archegonium not yet open; its neck portion is still covered at its point by the lid-cells d. In the ventral portion lies a large cell, which has divided into a small upper cell, the "ventral canal-cell" b, and a lower one, the oosphere. In (2) the neck portion of the archegonium is open; the oosphere has assumed a spherical form; the ventral canal-cell is shrivelled up. (3) A fertilized archegonium; the oosphere has become developed into an embryo, here consisting of eight cells. d is an involucre, which in *Marchantia* grows round the archegonium after fertilization. (After Sachs.)

(3) *Development of the Asexual Generation of the Sporogonium.*—Just as in the vegetative classification we are led in a continuous series from the simple thallose forms to the foliose forms, so in the perfecting of the fertilized oosphere into an embryo (here the sporogonium) there is a gradual advance from simple to more complex forms. The first result of fertilization always is that the oosphere becomes surrounded by a membrane, grows, and transforms itself by division into a cellular body. In the simplest case, in *Riccia* (fig. 7, *A*), the only differentiation which takes place in this cellular body is that it forms a wall-layer which is soon reabsorbed, while the whole of the interior cells form spores in such a way that by division four spores proceed from every mother-cell. In *Marchantia* (fig. 7, *B*) we find a separation taking place in the embryo, in which its inferior portion (that beneath the line 1, 1) becomes the short stalk of the sporogonium and its superior portion becomes the capsule. In the *Jungermanniеæ* (fig. 7, *C*, *E*, *F*) we find in the young embryo a group of cells from which proceed the mother-cells of the spores (shown by hatched lines in the figures); they are covered by a layer of cells which at a later period becomes the wall of the spore-capsule. Lower down (distinguished by a bracket in fig. 7, *C*) comes that part of the embryo out of which the stalk of the sporogonium is formed, while the cell *a* represents an appendage of the embryo. The inferior portion of the stalk often swells into a thickened foot, which frequently penetrates deeply into the tissue of the fertile shoot (fig. 8). The upper part of the sporogonium, in which the spores and elaters are formed, swells into a sphere.

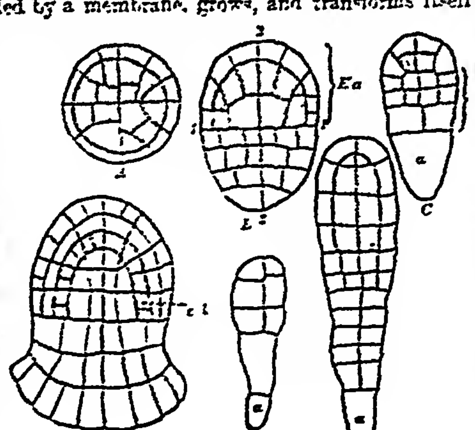

Fig. 7.—Young embryos of Liverworts in longitudinal section (semi-diagrammatic). The cells from the division of which the mother-cells of the spores proceed are shaded. *A*. A spherical embryo of *Riccia*, without stalk. *B*. *Marchantia polymorpha*; the upper part of the embryo *Ea* turns into the capsule, the lower part into the stalk. *C*. *Pellia epiphylla*; the cell *a* forms an appendage to the embryo; the stalk proceeds from the cells marked by brackets, and from those above is formed the capsule, whose wall and internal mass are now distinguishable. The whole inner portion of the capsule proceeds from the division of four cells. *D*. *Anthoceros laevis*; *col*, columella. *E*. *Jungermannia bicuspidata*. *F*. *Radula complanata*. *E* shows the arrangement of the cells of the embryo which is characteristic of the *Jungermanniеæ*; it is composed of a number of transverse disks, which always consist of four cells.

In the *Jungermanniеæ*, when the sporogonium attains maturity, the stalk becomes very considerably lengthened, the ventral part of the archegonium, which had hitherto kept pace with it in growth, flies asunder, and the capsule emerges. This opens in various ways. In the *Jungermanniеæ* the wall breaks up into four valves (fig. 4). The sporogonia of *Anthoceros* behave in a very peculiar manner. The period occupied by their development is much longer than that of the *Jungermanniеæ*. While they are discharging mature spores at their apex they are still growing at their base, and forming new spores. The sporogonium dehisces by two valves, and is traversed in the middle line by a longitudinal string of cells not employed in the formation of spores. This persists till the maturation of the sporogonium as a little column, and is termed the "columella" (see fig. 7, *D*). The cells from which the mother-cells of the spores proceed have here the form of a dome and enclose an inner portion which becomes the columella, while the inferior portion of the embryo becomes its foot. In *Dendroceros*, a foreign form of *Anthoceros*, it drives tubules resembling roots into the tissue of the plant on which the sporogonium is seated. There is no want of transitional steps between this method of formation of the sporogonia and that of the *Jungermanniеæ*. The species *Notothylas* is especially noteworthy in this respect.

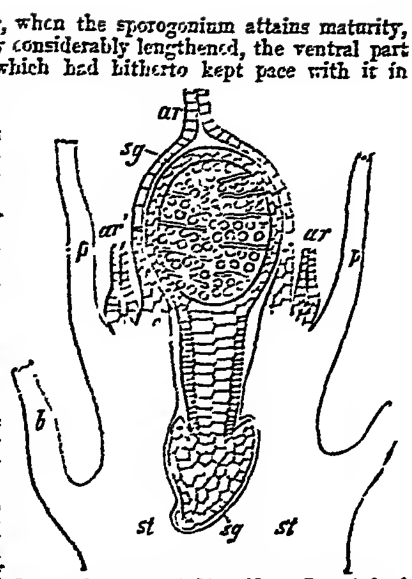

Fig. 8.—*Jungermannia bicuspidata.* Longitudinal section of the immature sporogonium *sg*, surrounded by *ar*, the calyptra (the ventral portion of the archegonium which has kept pace with it in growth). In the sporogonium three parts are to be distinguished: the globular capsule in which lie the mother-cells of the spores and the elaters, the cylindrical stalk which at a later period lengthens very considerably, and the swollen foot which has penetrated deeply into the tissue of the fruit-shoot. *ar'*, archegonia which have remained unfertilized; *p*, base of the perianthium; *st*, stem (fruit-shoot); *b*, leaf. (After Hofmeister.)

The spores, which proceed from one mother-cell by division into four parts, are enveloped by a membrane consisting of two layers—an outer one, which has the character of a cuticle in its great resistance to external agencies, and an inner one, which is composed of cellulose. The plants do not proceed directly from the germination of the spores; there is a pro-embryo of simple structure, which, however, in most cases passes over at its end into the plant itself. In the foliose *Jungermanniеæ* the first step in germination is the springing up of a row of cells in the cell at the end of which the growth of the shoot next takes place. The young germ-plant next develops leaves of very simple structure, and at first there generally appear on it only two rows of leaves at the sides. In *Radula*, however, and *Frullania*, both of them leafy forms, a cake-like cell-surface is first developed in germination; and it is from one of the cells of the margin of this that the growth of the leafy plant proceeds.

Classification of Liverworts

A. *Marchantiaceæ.*

I. *Riccieæ.*—The vegetative body is a dichotomously branched thallus, on the dorsal side of which are air-chambers, either covered by an epidermis like the *Marchantieæ*, or opening outwards in their whole breadth. On the under side of the thallus is a row of scale-shaped lamellæ, which become split up at a later period. The sexual organs are scattered on the dorsal side of the ordinary shoots. In the spore-cavity are neither elaters nor sterile cells.

II. *Corsinieæ.*—The organs of sex are united in groups, which stand in cavities on the dorsal side of the thallus. In the spore-space are sterile cells, which in *Boschia* are transformed into elaters. The dorsal side of the thallus possesses stomata.

III. *Marchantieæ.*—The thallus is ribbon-shaped, and has a layer of air-chambers on the dorsal side opening outwards through a stoma. On the ventral side are two rows of scales. In the spore-space are elaters. The formation of the "inflorescences" in the lowest forms agrees with those of *Corsinia*; in the highest forms they appear as branch-systems.

B. *Jungermanniaceæ.*

I. *Jungermannieæ.*—The vegetative body is a thallus without air-chambers, or is a leafy stem. Between these are transitional forms. The sporogonium is differentiated into capsule, stalk, and foot; the capsule dehisces by four valves.

(*a*) *Anacrogynous.*—The apex is not employed in the formation of the archegonium. To this division belong all the thal-

lose forms (including *Blasia* and *Fossombronia*), as well as *Haplomitrium Hookeri*. In *Riella* and *Sphærocarpus* the capsule is without elaters, but possesses sterile cells morphologically corresponding to them. All the others have elaters.

(*b*) *Acrogynous*.—The apex or the apical cell itself is employed in the formation of the archegonium. All the forms are foliose, except *Haplomitrium*, which also, in the development of its leaves, does not correspond with the foliose forms, but with *Fossombronia*.

II. *Anthocerotæ*.—Thallose forms. The archegonia, immediately on their first formation, are sunk into the tissue of the thallus. The antheridia stand in closed cavities. The formation of the sporogonium shows no distinction between stalk and capsule, but is pod-shaped and fixed by its swollen foot into the thallus. At maturity the sporogonium opens with two valves, between which the columella becomes visible. At its base it possesses a long and permanent growth.

II. Mosses (*Musci* or *Musci Frondosi*).

The Mosses proper play a much larger part in the economy of nature than the Liverworts; they occur in much greater quantity and are more widely distributed, the conditions of their production not being confined within such narrow limits. While the Liverworts, for the most part, thrive only in localities that are not too dry, though some forms that grow upon bark, such as *Radula* and *Frullania*, can even endure drought, Mosses, on the other hand, have an almost ubiquitous character. Many grow in water (*Conomitrium*, *Fontinalis*, &c.), in swamps (various kinds of *Hypnum* and others), on dry rocks (*Grimmia*, *Andreæa*), on roofs, in fields, and on trees,—in short, under favourable circumstances, a growth of Mosses develops itself almost everywhere. This is connected with the fact that very many have the capacity of enduring drought, and of suspending their growth while it continues and resuming it again in moist weather. Besides, a few, such as *Hypnum cupressiforme*, *Ceratodon*, *Barbula ruralis*, can grow upon any kind of substratum. Others grow by preference on organic substrata: as *Buxbaumia indusiata* on decayed trunks, *Splachnum* on old cowdung or on a damp humus-soil, *Orthotrichum* and the species of *Neckera* on the firm bark of trees, *Phascum* in manured fields, a great number like *Grimmia* and *Andreæa* on rocks. As regards the chemical quality of the substratum, we can distinguish between Mosses that live on chalk (*Seligeria*, the species of *Gymnostomum*, and some *Hypna*) and those that avoid chalk (*Andreæa*, *Dicranum*). The species of *Polytrichum* and *Thuidium abietinum* are fond of sandy soils, *Ephemerum*, *Fissidens taxifolius*, and others of loamy soils, while *Archidium phascoides* grows on muddy ground. This wide extension of the Leaf-mosses is rendered possible by their uncommonly great capacity for reproduction. Not only is the formation of spores in most species very extensively carried on, but we have to add to this the manifold production of asexual means of multiplication, such as gemmæ, &c. The sexual as well as the asexual generation of Mosses attains to a higher grade of perfection than that of Liverworts.

(1) *The Sexual Generation*.—The extent of the sexual generation of the Moss-plants proper varies within wide limits. While the stem of *Ephemerum* and some species of *Phascum* appears in the form of a small bud, often scarcely visible to the naked eye, there are species of more than 4 inches in length, as *Sphagnum*, *Fontinalis*, and the tropical species *Spiridens*. In every case, however, we have here a really leafy stem; no thallose forms exist.

The leaves are simple and always small. They either consist of one layer in their whole extent, or are traversed by a mid-rib of several layers, which is often of rather complex structure, and considerable cases walled and thin-walled tissue-elements, of many spermatozoids give mechanical firmness to the leaf, one or very few of the in the latter that the conveyance to the stem of the matter formed in the leaf takes place. In the species of *Polytrichum* the middle nerve occupies the greatest part of the leaf, and is covered with lamellæ, which consist of cells bearing chlorophyll. Instead of these lamellæ, we find in some other Mosses simple rows of cells, as in *Pharomitrium subsessile*. A peculiar structure of the leaf is also found in *Leucobryum glaucum* and *Sphagnum*. The first-named Moss forms thick greenish-white turfs in damp spots. A transverse section through a leaf shows it to be composed of two (or three) layers of cells. Above and below is a layer of large cells devoid of contents, the membrane of which is perforated in various places, so that the cavities of the individual cells communicate with each other; thus arises a system of capillary tubes which suck up water and retain it like a sponge. Between the angles of every two of these colourless cells we find inserted a cell containing chlorophyll. The colourless cells are filled with air instead of water, and thus the whole plant has a whitish appearance (*Leucobryum*), while the green hue comes out at the approach of moisture. The leaves of *Sphagnum* possess a similar structure. In these too are perforated cells devoid of contents, and surrounded by the meshes of cells containing chlorophyll. The inner wall of the empty cells devoid of chlorophyll is for the most part set with peculiar thickenings of annular or spiral form (fig. 9, *f*), which give

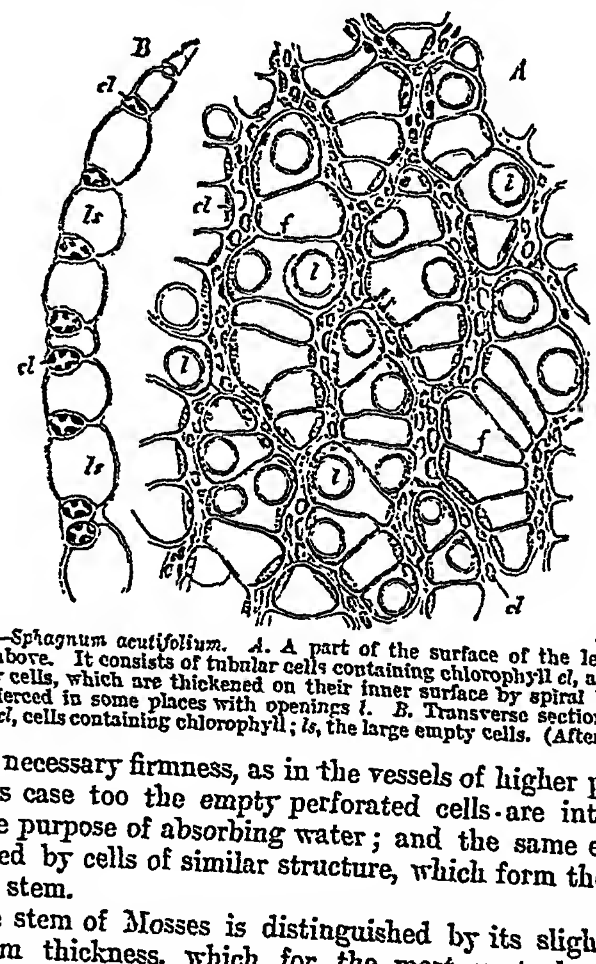

Fig. 9.—*Sphagnum acutifolium*. *A*. A part of the surface of the leaf, seen from above. It consists of tubular cells containing chlorophyll *cl*, and large empty cells, which are thickened on their inner surface by spiral bands *f*, and pierced in some places with openings *l*. *B*. Transverse section of the leaf; *cl*, cells containing chlorophyll; *ls*, the large empty cells. (After Sachs.)

it the necessary firmness, as in the vessels of higher plants. In this case too the empty perforated cells are intended for the purpose of absorbing water; and the same end is attained by cells of similar structure, which form the rind of the stem.

The stem of Mosses is distinguished by its slight but uniform thickness, which for the most part does not exceed that of a thick thread. Compared with this delicacy, the compact, firm, and tough quality of the corresponding forms in higher plants is so much the more striking. It depends on the fact that the exterior layers of cells in the stem have thickened cell-walls, generally of a brown colour, while the central parts have thin walls. The differentiation of the tissues reaches its highest point in *Polytrichum*, *Hookeria*, *Splachnum*, and others. Strings of separated cells pass from the leaves into the stem, and apply themselves to its central tissue, which is of different conformation from the rest of the tissue of the stem,—a circumstance which requires mention because this is the first indication of the fact of such extensive occurrence

among "vascular" plants that the vascular bundles which run off from the leaf pass into the stem and there apply themselves to others. The stems are thickly set with leaves. It is but seldom that these stand in two rows on the sides, as in *Fissidens*, *Conomitrium*, and the sterile shoots of *Schistostega*. The last-named plant is of special interest as possessing two kinds of shoots of totally different appearance. The fertile ones have their leaves placed on all sides of the stem in a spiral manner: the sterile ones, on the other hand, have leaves placed on two sides, and have the appearance of a fern-leaf. This position, however, only comes to pass through a shifting and twisting of the stem. Originally, in the bud, the leaves of the sterile stems stand in a spiral line. On examination of the end of the stem it is found that the growing point from which the leaves arise contains, as in the foliose Liverworts, an apical cell of the form of a three-sided pyramid with a vaulted base. By means of partition walls which are successively parallel to one of the side walls of the apical cell "segments" are cut off; and from each of these proceeds a leaf, as well as a part of the rind of the stem and of the inner tissue. On the direction of the partition walls in the apical cell depends likewise the arrangement of the leaves. The branches do not spring as in most phanerogamous plants from the axil of a leaf, but from the upper surface of the stem below a leaf, and only out of one of its cells, which becomes the apical cell of the branch.

In the relation of the ramification to the general structure of the moss-plant two leading classes have to be distinguished—the *acrocarpous* and *pleurocarpous* Mosses. In the former the growth of the stalk concludes with the formation of a sporogonium; for the archegonium, out of which the former springs, proceeds from the apical cell itself. In the pleurocarpous Mosses the sporogonium stands on the tip of a side-branch, and the growth of the principal stem is thus not interfered with by fructification. In many acrocarpous Mosses the stalk dies after fructification, and the Moss is then an annual, as in many *Phascaceæ*. In those acrocarpous Mosses which are perennial the further development is taken up by a side-branch, and a so-called "innovation" is formed. By the dying away of the principal stem, these innovation-shoots become at a later period independent plants. The roots consist of simple rows of cells, springing from the surface of the stem, especially at its base (see p. 72).

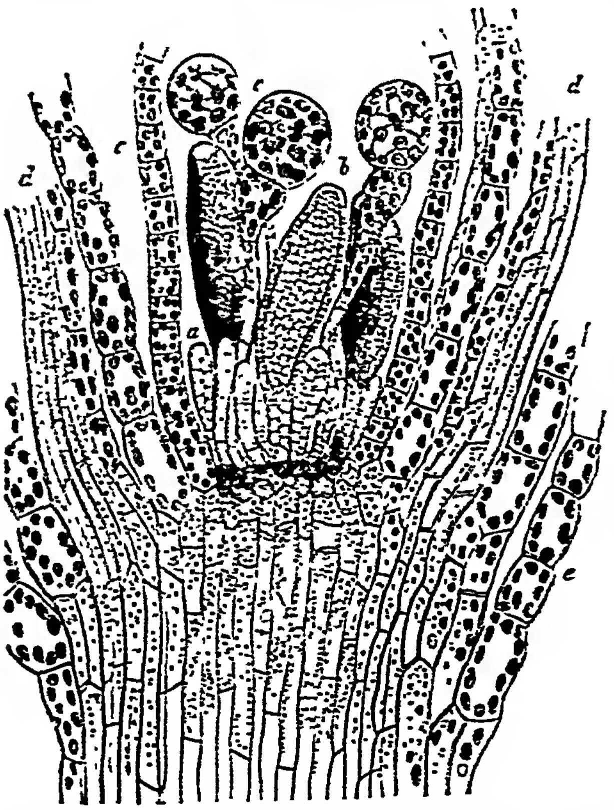

FIG. 10.—Longitudinal section through the summit of a small male plant of *Funaria hygrometrica*, with antheridia in various stages of development. *a* is a young antheridium—at its point is a "two-edged" apical cell; *b*, an antheridium, nearly mature; *c*, paraphyses, hair-like structures which stand between the antheridia and of which the terminal cells are swollen into a globular form; *d*, section of leaves through the mid-rib; *e*, section of leaves through the leaf-surface (lamina). Magnified 200 diameters. (After Sachs.)

(2) *The sexual organs* of the Leaf-mosses, the antheridia and the archegonia, in their mature condition correspond in the main with those of the Liverworts, from which, however, they differ somewhat in their development. They occur generally in groups at the extremity of a shoot. Such groups containing, as the case may be, either solely antheridia, or solely archegonia, or a mixture of the two, are termed "flowers." An exception to this condition of the antheridia is found in *Sphagnum* (fig. 11, *A*). Here the antheridia do not stand in groups on the summit of the male branch, but are arranged along it, so as to stand beneath the leaves on the prolonged axis of the shoot. In the rest of the Mosses, with the exception of *Polytrichum*, the first antheridium (or archegonium) of a group proceeds from the apical cell itself; and thus the growth of the shoot connected with it is closed. The general character of the male "flowers" is very various, in the form of buds, heads, or disks. They are enveloped by a number of leaves, the "perigonium" (fig. 11). The male plants of diœcious Mosses are often considerably smaller than the female ones. This is the case with *Funaria hygrometrica*, and to a remarkable extent with *Dicranum undulatum* and *Leucobryum glaucum*. Diœcious Mosses are frequently sterile on account of the absence of one of the sexes. The female "flowers" (fig. 12) are in the shape of buds, enveloped by a number of leaves, which become smaller towards the inside. The archegonia have in general the same structure as those of Liverworts, but are distinguished by a very much developed stalk, diminishing towards the base in the form of a wedge

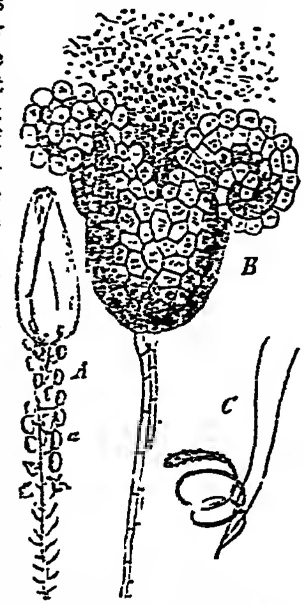

FIG. 11.—*Sphagnum acutifolium*. *A*. A male branch partially deprived of its leaves to show the antheridia *e*. *B*. An open antheridium, very highly magnified. *C*. A mature motile spermatozoid. (After Schimper.)

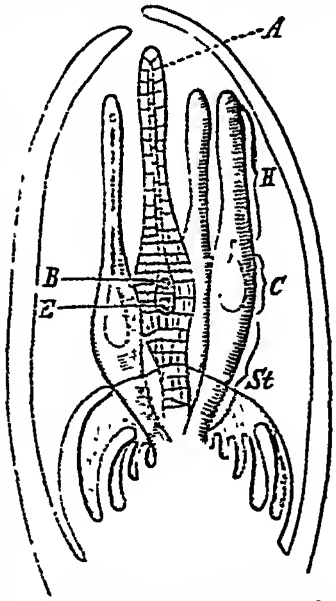

FIG. 12.—Longitudinal section through the female "flower" of *Sphagnum squarrosum*, which shows four archegonia with long stalks. *H*, the neck portion; *C*, the ventral portion; *St*, the stalk; *B*, ventral canal-cell; *E*, oosphere. The archegonium in the middle has proceeded from the apical cell of the shoot.

(fig. 12). They originate, as do the antheridia, from a single cell.

(3) *The development of the fertilized oosphere* into the sporogonium differs considerably from that of the Liverworts, both as regards the external processes of growth and as regards the differentiation in the interior of the embryo. In the first of these points the greatest resemblance to the Liverworts is exhibited by *Sphagnum*. Here the sporogonium continues almost till maturity to be enclosed by the ventral portion of the archegonium—the calyptra,—which keeps pace with it in growth, and which is irregularly ruptured by it at the period of maturity. *Archidium*, one of the *Phascaceæ*, behaves similarly. In all the other Mosses, however, the sporogonium at an early period bursts through the ventral portion of the archegonium, tearing off the calyptra at its base and raising it up as a cap. The sporogonium possesses a stalk which grows up gradually, but which in *Sphagnum*, *Andreæa*, and *Archidium* is very short. In the two first-named genera the shortness of the stalk is made up for by a stalk-like elongation of that portion of the stem on which the archegonium is placed. Thus arises a false stalk, a "pseudopodium," which is to be distinguished from the real stalk, which belongs to the sporogonium. The capsule is often of complex structure. In the *Bryineæ* it possesses a distinct epidermis, often provided with stomata, which is altogether wanting in the vegetative parts of Mosses. A few layers of cells are united to the epidermis, and together with it form the wall. The interior tissue is never entirely employed in the formation of spores, but a part of it remains as a sterile cell-body—the columella (fig. 13, *co*)—with the exception of *Archidium*, which in this respect approaches the Liverworts. The embryo, the young sporogonium, is originally fusiform (fig. 14, *B*, *C*), and is differentiated into capsule and stalk (*seta*). The latter commonly penetrates into the tissue of the fruit-shoot, which forms, outside the base of the sporogonium, an exuberant growth like a fence—the "vaginula"—on which we not unfrequently find archegonia that have miscarried (fig. 13, *v*).

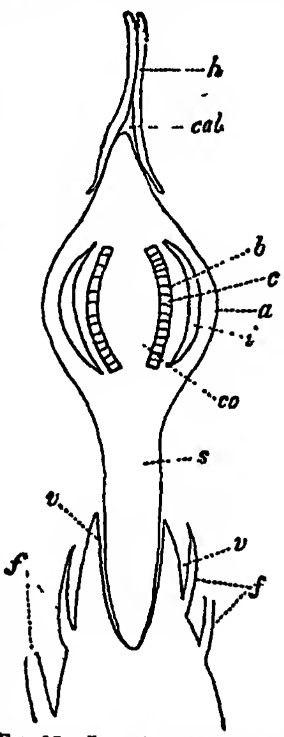

FIG. 13.—Longitudinal section through a half-developed sporogonium of *Phascum bryoides*. (The cells are not shown.) The sporogonium has torn away the ventral portion of the archegonium from its base and lifted the upper part of the archegonium as a cap (calyptra; *cal* in fig.). Beneath the calyptra is the capsular portion of the sporogonium. In its wall-layer there has been formed an annular intercellular space *a*, filled with air. The cells from which the mother-cells of the spores proceed (archesporium) are marked *c*; *co*, columella; *b*, endotherium; *h*, neck of archegonium; *i*, air-space; *s*, stalk of the sporogonium (seta); *v*, vaginula; *f*, leaves of the shoot that bears the archegonia. Magnified 60 diameters.

In Mosses, as in Liverworts, the spores proceed from the division of one mother-cell into four parts. The phenomena of their germination are very peculiar. In the great majority of the Mosses there arise from the germinating spore cellular filaments resembling Confervæ. They have quite the appearance of Algæ, and formerly were even confounded with them. They bear the name of *protonema*, and often form a thick green covering on the ground in forests. Such a protonema consists of two parts: one above and the other below the ground. Both are rows of cells, but those above the ground contain chlorophyll and have transverse walls placed rectangularly, while those below the ground contain no chlorophyll and their transverse walls are placed obliquely. They serve as roots for the protonema, and of similar structure are the roots (rhizoids) which spring from the surface of the leafy stem, especially from its base. On this protonema, and especially from the basal cells of the threads which are above ground, the moss-stem is formed. This originates from an outward pouching of one of these cells, and this becomes the apical cell of a moss-stem. Several moss-plants may be formed on one and the same protonema, which has itself proceeded from one spore. The spores of the Bog-moss (*Sphagnum*) form quite another kind of pro-embryo when they germinate on damp earth. They then transform themselves into an intricately ramified expansion or cell-surface; and any cell of this surface may then become the apical cell of the stem. When they germinate in water the spores of *Sphagnum* form a thread-like pro-embryo. In some other Mosses too, especially *Andreæa*, *Tetraphis*, and *Diphyscium*, remarkable forms of pro-embryo occur, which, however, can only be alluded to here. In no case does a moss-spore grow directly into a moss-stem.

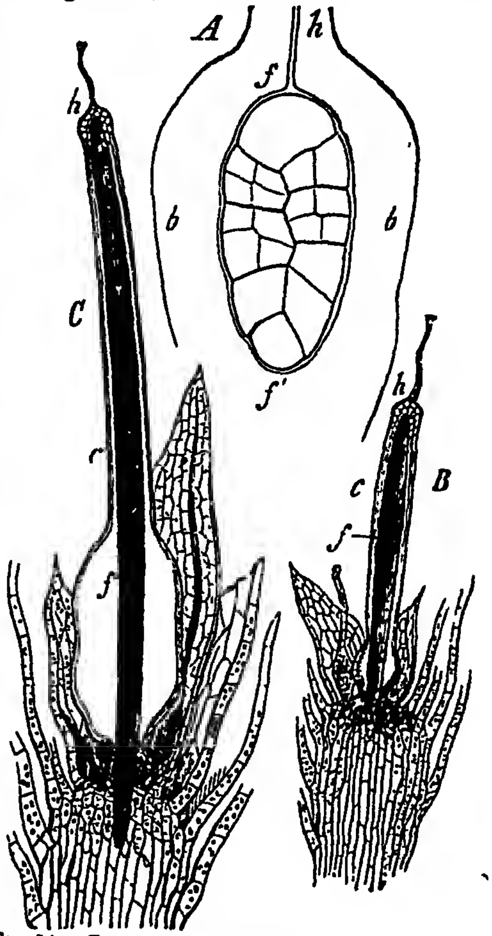

FIG. 14.—*Funaria hygrometrica*. *A*. Rudiment of the sporogonium or embryo *ff'*, in the ventral portion of the archegonium. The embryo is a cellular body, showing at its point a large "two-edged" wedge-shaped apical cell, which forms segments on the right and left. *B* and *C* are further stages of development of the sporogonium *f*, and of the calyptra *c*. The inferior portion of the embryo has penetrated into the tissue of the shoot. *h*, neck of the archegonium.

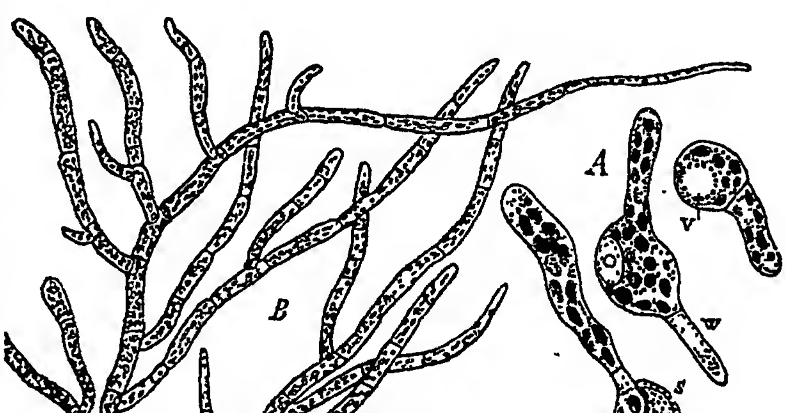

FIG. 15.—*Funaria hygrometrica*. *A*. Germinating spores; *v*, vacuole; *w*, root; *s*, exosporium. *B*. Part of a developed protonema, about three weeks after germination; *h*, a procumbent primary shoot with brown wall and oblique septa, out of which arise ascending branches of limited growth *b*; *K*, rudiment of a leaf-bearing axis with root *w*. *A* is magnified 550, *B* about 90 diameters.

Mosses propagate themselves very extensively, not only by means of spores, but in a vegetative way. Every one of the hair-shaped roots (rhizoids) which spring out of the stem has the power, when exposed to the light, of forming protonema, and moss-buds upon this. On this depends the fact that the Mosses which grow on tiled roofs (*Grimmia* and others) are hardly to be extirpated. Even if the turf is removed, the roots that have made their way

into the pores of the tiles still survive, and develop protonema, and new moss-plants upon this. In *Phascum* and *Ephemerum*, which are apparently annual Mosses, the protonema is perennial, and forms new plants in the following year. Gemmæ also arise in abundance on the protonema (*e.g.*, of the species of *Barbula*)—cellular bodies which are surrounded by a dark-coloured membrane, and whose cells are densely filled with a store of material. They are able to endure drought, and on germinating they either form moss-buds directly or protonema in the first place. Protonema may also proceed directly from the cells of the leaves and stems of moss-plants, and thus subserve their multiplication. Portions even of the sporogonium may transform their cells back into protonema. If we cut off young sporogonia and place them in damp sand, there will arise from their interior cells (or the wall of the capsule) threads of protonema, on which new plants spring up. Many Mosses also possess special gemmæ. In *Tetraphis pellucida* they are stalked cellular bodies, enveloped by a leafy calyx, from which at a later period they fall away. In *Aulacomnium androgynum* they spring from the extremity of a leafless prolongation of the stalk, in *Grimmia Hartmanni* and *Barbula papillosa* from the leaves, &c.

Classification of Mosses.

1. *Sphagnaceæ*.—The Turf-mosses are characterized as well by their anatomical structure as by the development of their sporogonia. The stem, which at first is unbranched, possesses roots only in its earliest stage. The stems then stand in a thickly-set turf, and receive water through the whole of their surface. The ramification is very abundant. Two kinds of branches are formed in the terminal buds—long whip-shaped "flagellæ" which hang down, and whose duration is annual; and besides these there is formed every year, after the fruit has reached maturity, a side shoot called an "innovation," which acts in the same way as the main stem, and at a later period becomes an independent plant. The sexual organs, antheridia and archegonia, are developed on the side branches. The peculiar structure of the leaves has been already mentioned. That of the stem is analogous to it. The latter possesses a rind, formed out of cells with thin walls, whose protoplasmic contents have completely disappeared. Like the empty cells of the leaf, they are penetrated by openings, and thus form a system of narrow capillary tubes which stand in connexion with each other and open outwards, and through which the water mounts upwards.

The branches that bear the male "flowers" make an approach to those of the Liverworts in the fact that the antheridia do not stand on the summit of the shoot, but singly close to its leaves. On the other hand, the archegonia agree in their position and development with those of the other Mosses. The embryo—the young sporogonium—is at first a pear-shaped body of cellular tissue, the basal portion of which penetrates deeply into the soft tissue of the fruit-branches on which the archegonium is seated. The sporogonium differs considerably from that of the other Mosses. Those cells which give origin to the mother-cells of the spores—termed collectively "archesporium"—form a dome-shaped layer in the upper portion of the embryo; thus they are not traversed by the sterile cellular tissue, the columella. Each mother-cell is divided as usual into four spores. The short stalk of the capsule extends itself at maturity only so far as to cause the sporogonium to break through the calyptra, the place of a stalk being practically supplied by the "pseudopodium."[1] The pro-embryo is a cell-surface.

2. The *Andreaaceæ* are small blackish Mosses growing on rocks. Their antheridia resemble those of the other Mosses. The development of the embryo is anomalous. The archesporium is, as in *Sphagnum*, a dome-shaped layer of cells. On the extremity of the mature capsule is placed the calyptra, which has been torn away, as a delicate cap. The mode of dehiscence of the capsule here reminds us of the Liverworts. This takes place by four longitudinal clefts, which allow the exit of the spores, and are open in dry and closed in damp weather. In this group also the stalk of the sporogonium remains short, its place being supplied by a "pseudopodium."

3. The *Phascaceæ*, which are small and generally annual Mosses, are distinguished from the following division by the fact that the capsule does not open by separation of a lid, but remains closed, and the spores are not set free till the wall of the capsule decays. A remarkably anomalous form is *Archidium*; the development of

[1] The possession of an elastic stalk has this advantage for the sporogonium, that it promotes the scattering abroad of the spores by means of the wind.

its embryo reminds us of that of the Liverworts; the mature sporogonium also possesses no calyptra, but breaks through the ventral portion of the archegonium like that of *Sphagnum* and that of the Liverworts. The *Phascaceæ* are termed "cleistocarpous" in contradistinction to the "stegocarpous" Mosses.

4. The *Bryinæ* comprehend by far the greatest number of all the species of Mosses. They are characterized above all by the structure of their sporogonia. Here the parts of the latter are always the longer or shorter bristle-shaped stalk (seta), the capsule, and the calyptra carried up on its summit. That part of the stalk where it passes into the capsule is termed *apophysis*; on its epidermis, as well as on that of the capsule, we almost always find stomata. As regards the structure of the capsule, at a very early period a space filled with air makes its appearance, which divides the interior mass from the wall, which is composed of several layers. This interior complex mass of tissue consists of those cells which give rise to the mother-cells of the spores (the archesporium), of a few layers of cells which surround these only externally, and of an inner mass of tissue, the columella. The latter, however, passes in this case through the cells of the archesporium; these latter form, as in the *Phascaceæ*, a stratum of cells which has the form of a barrel, open above and below (fig. 13), and encloses the columella. The *Bryinæ* are also characterized by the way in which the capsule opens. The upper part of the wall of the capsule is in this case always thrown off as a lid (operculum). This happens in one of two ways: either a layer (or several layers of cells lying upon one another), placed between the inferior portion of the capsule and the operculum, forms a ring (annulus), the cell-walls of which become thickened and partially swollen, so that the annulus becomes loosened and thus causes separation of the operculum and the capsule from each other, or there remains simply a thin-walled annular zone of cells belonging to the wall of the capsule, which splits asunder in dry weather. When the operculum falls away the margin of the open capsule appears in most cases set round with a single or double ring of tooth-like formations, which are termed *peristome*. This is wanting in *Gymnostomum* and *Hymenostomum*. It occurs in its simplest form in *Tetraphis*. Here the epidermis of the upper conical portion falls off as an operculum, while the whole tissue that lies beneath splits crosswise into four valves, which form the peristome. In the other Mosses, with the exception of *Polytrichum*, the teeth of the peristome have an essentially different origin. They are in fact nothing but the thickened portions of cell-membranes, whose unthickened portions have perished and been torn asunder. Fig. 16 shows a portion of a longitudinal section through the upper part of the capsule of *Funaria hygrometrica*.

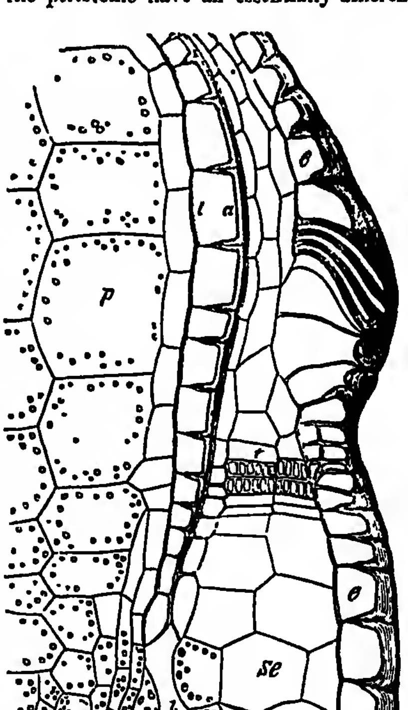

Fig. 16.—Part of a longitudinal section through the upper part of a capsule of *Funaria hygrometrica*. At *i* and *a* are the teeth of the peristome; *t*, pointed cells. (After Sachs.)

The capsule possesses a brown epidermis *e*, whose walls are greatly thickened; *se* is the tissue that lies between the epidermis and the air-spaces *h*, *l* of the capsule; *s* the mother-cells of the spores, and farther inwards follows the columella. Immediately above the air-space rises the stratum of cells which forms the peristome, of one tooth of which a longitudinal section is given in fig. 16. It arises from the great thickening of the outer side of the walls of a row of superposed cells. At maturity the upper portion of the wall of the capsule falls off as an operculum, the cells marked *p* disappear, and only the thickened parts of the cell-membranes remain as the teeth of the peristome. In *Funaria* and in other cases the peristome is double, for those cell-walls (fig. 16, *i*)

which look inwards of the stratum of cells which forms the peristome have also in these cases become somewhat thickened, and continue as "cilia," while the thin portions of membrane placed at right angles to them perish. In other cases (*Fontinalis antipyretica*) the peristome forms a lattice-work. The number of teeth in the peristome is always four, or a *multiple of four*. They are very hygroscopic: their function is to close up the opening of the capsule in wet weather, and so to hinder the exit of the spores, which are scattered abroad by the wind. In the same way also any germination of the spores in the interior of the capsule is prevented. The columella shrivels up after the formation of the spores, so that at that time we find nothing in the capsule but the spore-dust. The *Polytrichaceæ* have special arrangements for the protection of the spores. Here the opening of the capsule is covered over by a kind of plate ("epiphragma"), which is supported by thirty-two or sixty-four teeth, consisting of fibre-like cells.

Retrospective View.—Comparing generally the Mosses with the Liverworts, we see that, however great the variety of the forms they comprehend, they still form two connected series. In several of the subdivisions of the Leaf-mosses conditions occur which remind us of the Liverworts. Such are, in *Sphagnum*, the form and position of the antheridia, the tearing open of the ventral portion of the archegonium, and the want of a "calyptra" on the sporogonium which proceeds from it. This last is also found in *Andreæa*, in which the method of opening of the sporogonium likewise reminds us of the Liverworts. Among the *Phascaceæ*, the *Archidium* agrees with Liverworts in the absence of a columella. Some few cells in the interior of the sporogonium are formed into mother-cells of spores, and push aside the rest of the tissue. Here, too, the calyptra is absent.

The simplest Liverworts make a near approach to the Algæ. The sporogonium of *Riccia* is of scarcely higher organization than the mass of tissue which proceeds from the fertilized ovum-cell of *Coleochæte*, a green freshwater Alga. Among plants of a higher order we find no group closely allied to the Muscineæ. It is true that the Ferns have a perfectly analogous alternation of generations, but it is not a sporogonium which is produced from the fertilized oosphere, but the leafy fern-plant. No transitional forms occur between these two sections; the chasm which divides them is the widest with which we are acquainted in the whole vegetable kingdom. (K. E. G.)

MUSES, The, according to the view which prevailed among the Greek writers and has become a commonplace in modern literature, were nine goddesses who presided over the principal departments of letters: Calliope, Muse of epic poetry; Euterpe, of lyric poetry; Erato, of erotic poetry; Melpomene, of tragedy; Thalia, of comedy; Polyhymnia of the hymn as used in the worship of the gods; Terpsichore, of the song and the dance which formed its accompaniment; Clio, of history; and Urania, of astronomy. They are represented in ancient art as fully draped, and distinguished by attitude, dress, and symbols appropriate to the arts over which they presided. This conception of them prevails in earlier literature also. They are daughters of Zeus and Mnemosyne, and sing and dance in chorus round the altar of Zeus on Olympus; they sing the deeds of gods, and of men, the heroes, especially of Zeus. At the banquets of the gods their songs are heard. They honour the marriage of Cadmus and Harmonia, and the marriage of Peleus and Thetis; they sing at the death of Achilles, and they weep over men. They know all things, and they inspire their chosen poets and musicians, who are usually regarded as their descendants—Orpheus, son of Calliope, and others of the Muse.

The Muses, as the Greeks knew them, still preserve traces of the character of the local goddesses of the earlier religion. Though Homer calls them Olympian (*Iliad* ii. 491; *Odyssey* (xxiv. 60), yet this only represents the later religious stratum out of which the older religion of the Muses had two chief seats, on the northern slope of Mount Olympus around Dion in Pieria, by the holy springs Leibethron and Pimpleia, and on the slope of Mount Helicon near Ascra and Thespiæ. Nothing is known of the cultus in its older form, but it appears to have been connected with the religion of Dionysus. The Muses must have been originally a variety of the Nymphs (see Nymphs), the spirits of nature who live in the fountains and forests; hence they are associated with Pegasus, the winged horse of the thunder-cloud. The half-mythic race called Thracian, which is specially associated with the two localities where the worship of the Muses had its seat, survived in Greek memory as a race of bards; and this character of the race coloured its conception of the spirit-life which it saw in nature. The spirits who know or who remember (Μοῦσα = Μοντια, from *man*, to think) sang to them in the voice of the water and the trees. At first they gave no definite number or form to their conception of these spirits; the number nine is the invention of a later time and of a different order of thought, and some accounts speak of three Muses or of a single Muse.

MUSHROOM. There are few more useful, more easily recognized, or more delicious members of the vegetable kingdom than the common mushroom (*Agaricus campestris*, L.). It grows in short grass in the temperate regions of all parts of the world. Many edible Fungi depend upon minute and often obscure botanical characters for their determination, and may readily be confounded with worthless or poisonous species, but that is not the case with the Common Mushroom, for, although several other species of *Agaricus* somewhat closely approach it in form and colour, yet the true mushroom, if sound and freshly gathered, may be distinguished from all other Fungi with great ease. It almost invariably grows in rich, open, breezy pastures, in places where the grass is kept short by the grazing of horses, herds, and flocks. Although this plant is popularly termed the "meadow mushroom," it never as a rule grows in meadows. It never grows in wet boggy places, never in woods, or on or about stumps of trees. An exceptional specimen or an uncommon variety may sometimes be seen in the above-mentioned abnormal places, but the best, the true, and common variety of our tables is the produce of short, upland, wind-swept pastures. A true mushroom is never large in size; its cap very seldom exceeds 4, at most 5 inches in diameter. The large examples measuring from 6 to 9 or more inches across the cap belong to *Agaricus arvensis* (Sch.), called from its large size and coarse texture the Horse Mushroom, which grows in meadows and damp shady places, and though generally wholesome is coarse and sometimes indigestible. The mushroom usually grown in gardens or hot-beds, in cellars, sheds, &c., is a distinct variety, known as *Agaricus hortensis* (Cke.). This is a compact and inferior form of the true mushroom, or it may indeed be a hybrid or even a distinct species.

The parts of a mushroom consist chiefly of stem and cap; the stem is furnished with a clothy ring round its middle, and the cap is furnished underneath with numerous radiating coloured gills. In the accompanying illustration (1) represents a section through an infant mushroom, (2) a mature example, and (3) a longitudinal section through a fully-developed mushroom. The cap D, E is fleshy, firm, and white within, never thin and watery; externally it is pale brown, dry, often slightly silky or floccose, never viscid. The cuticle of a mushroom readily peels away from the flesh beneath, as shown at F. The cap has a narrow dependent margin or frill, as shown at G, and in section at H; this dependent frill originates in the rupture of a delicate continuous wrapper, which in the infancy of the mushroom entirely wraps the young plant; it is shown in its continuous state at J, and at the moment of rupture at K. The gills underneath the cap L, M, N are at first

white, then rose-coloured, at length brown-black. A point of great importance is to be noted in the attachment of the gills near the stem at O, P; the gills in the true mushroom are (as shown) usually more or less free from the

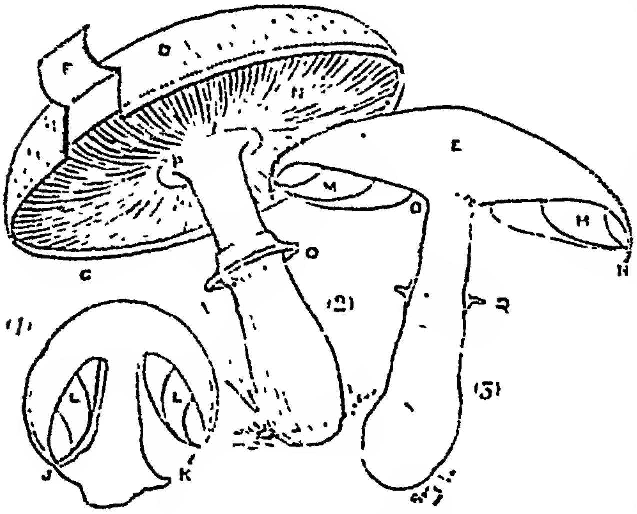

FIG. 1.—Pasture Mushroom (*Agaricus campestris*, L.).

stem, they never grow boldly against it or run down it; they may sometimes just touch the spot where the stem joins the bottom of the cap, but never more; there is usually a slight channel, as at P, all round the top of the stem. When a mushroom is perfectly ripe and the gills are brown-black in colour, they throw down a thick dusty deposit of fine brown-black or purple-black spores; it is essential to note the colour. The spores on germination make a white felted mat, more or less dense, of mycelium; this, when compacted with dry, half-decomposed dung, is the mushroom spawn of gardeners (see HORTICULTURE, vol. xii. p. 284). The stem is firm, slightly pithy up the middle, but never hollow; it is furnished with a floccose ring near its middle, as illustrated at Q, Q; this ring originates by the rupture of the thin general wrapper K of the infant plant. On being cut or broken the flesh of a true mushroom remains white or nearly so, the flesh of the coarser Horse Mushroom changes to buff or sometimes to dark brown. To summarize the characters of a true mushroom:—it grows only in pastures; it is of small size, dry, and with unchangeable flesh; the cap has a frill; the gills are free from the stem, the spores brown-black or deep purple-black in colour, and the stem solid or slightly pithy. When all these characters are taken together no other mushroom-like fungus—and nearly a thousand species grow in Britain—can be confounded with it.

Like all widely-spread and much-cultivated plants, the edible mushroom has numerous varieties, and it differs in different places and under different modes of culture in much the same way as our kitchen-garden plants differ from the type they have been derived from, and from each other. In some instances these differences are so marked that they have led some botanists to regard as distinct species many forms usually esteemed by others as varieties only.

A small variety of the common mushroom found in pastures has been named *A. pratensis* (Vitt.); it differs from the type in having a pale reddish-brown scaly top, and the flesh on being cut or broken changes to pale rose-colour. A variety still more marked, with a darker brown cap and the flesh changing to a deeper rose, and sometimes blood-red, has been described as *A. rufescens* (Berk.). The well-known compact variety of mushroom-growers, with its white cap and dull purplish clay-coloured gills is *A. hortensis* (Cke.). Two sub-varieties of this have been described under the names of *A. Buchanani* and *A. elongatus*, and other distinct forms are known to botanists. A variety also grows in woods named *A. silvicola* (Vitt.); this can only be distinguished from the Pasture Mushroom by its elongated bulbous stem and its externally smooth cap. There is also a fungus well known to botanists and cultivators which appears to be intermediate between the pasture variety and the wood variety, named *A. vaporarius* (Otto). The large rank Horse Mushroom, now generally referred to as *A. arvensis* (Sch.), is probably a variety of the Pasture Mushroom; Sowerby has described it under the name of *A. Georgii* and Dr Badham as *A. exquisitus*; it has also been published as *A. edulis*. It grows in rings in woody places and under trees and hedges in meadows: it has a large scaly round cap, and the flesh quickly changes to buff or brown when cut or broken; the stem too is hollow. An unusually scaly form of this has been described as *A. villaticus* and another as *A. augustus*. Dr Badham has also described a variety under the name of *A. anceps*.

A species, described by Berkeley and Broome as distinct from both the Pasture Mushroom and Horse Mushroom, has been published under the name of *A. eleusis*. This grows under oaks, in clusters,—a most unusual character for the mushroom. The species is said to be excellent for the table. An allied fungus peculiar to woods, with a less fleshy cap than the true mushroom, with hollow stem, and strong odour, has been described as a close ally of the Pasture Mushroom under the name of *A. silvaticus* (Sch.); its qualities for the table have not been described.

Many instances are on record of symptoms of poisoning, and even death, having followed the consumption of plants which have passed as true mushrooms; these cases have probably arisen from the examples consumed being in a state of decay, or from some mistake as to the species eaten. It should always be specially noted whether the fungi to be consumed are in a fresh and wholesome condition, otherwise they act as a poison in precisely the same way as does any other semi-putrid vegetable or putrid meat. Many instances are on record where mushroom-beds have been invaded by a growth of strange fungi and the true mushrooms have been ousted to the advantage of the new-comers; such instances are very perplexing, but they tend to show that a proper supervision should be kept over fungi when used for food as over other vegetables, fruit, meat, and fish. When mushrooms are gathered for sale by persons unacquainted with the different species mistakes are of frequent occurrence. A very common spurious mushroom in markets is *A. velutinus* (P.), a slender, ringless, hollow-stemmed, black-gilled fungus, common in gardens and about dung and stumps; it is about the size of a mushroom, but thinner in all its parts and far more brittle; it has a black hairy fringe hanging round the edge of the cap when fresh. Another spurious mushroom, and equally common in dealers' baskets, is *A. lacrymabundus* (Fr.); this grows in the same positions as the last, and is somewhat fleshier and more like a true mushroom; it has a hollow stem and a slight ring, the gills are black-brown mottled and generally studded with tear-like drops of moisture. In both these species the gills distinctly touch and grow on to the stem. Besides these there are numerous other black-gilled species which find a place in baskets,—some species far too small to bear any resemblance to a mushroom, others large and deliquescent, generally belonging to the stump- and dung-borne genus *Coprinus*. The true mushroom itself is to a great extent a dung-borne species, therefore mushroom-beds are always liable to an invasion from other dung-borne forms. The spores of all fungi are constantly floating about in the air, and when the spores of dung-infesting species alight on a mushroom-bed they find a nidus already prepared that exactly suits them; and if the spawn of the new-comer becomes more profuse than that of the mushroom the stranger takes up his position at the expense of the mushroom. There is also a fungus named *Xylaria vaporaria* (B.), which sometimes fixes itself on mushroom-beds and produces such an enormous quantity of string-like spawn that the entire destruction of the bed results. The spawn is sometimes so profuse that it is pulled out of the beds in enormous masses and carted away in barrows.

Sometimes cases of poisoning follow the consumption of what have really appeared to gardeners to be true bed-mushrooms, and to country folks as small Horse Mushrooms. The case is made more complicated by the fact that these highly-poisonous forms now and then appear upon mushroom-beds to the exclusion of the mushrooms. This dangerous counterfeit is *A. fastibilis* (Fr.), or sometimes *A. crustuliniformis* (Bull.), a close ally if not indeed a mere variety of the first. A description of one will do for both, *A. fastibilis* being a little the more slender of the two. Both have fleshy caps, whitish, moist, and clammy to the touch; instead of a pleasant odour, they have a disagreeable one; the stems are ringless, or nearly so; and the gills, which are palish clay-brown, distinctly touch and grow on to the solid or pithy stem. These two fungi usually grow in woods, but sometimes in hedges and in shady places in meadows, or even, as has been said, as invaders on mushroom-beds. The pale clay-coloured gills, offensive odour, and clammy or even viscid top are decisive characters. A reference to the accompanying illustration (fig. 2), which is about one-half natural size, will give a good idea of *A. fastibilis*; the difference in the nature of the attachment of the gills near the stem is seen at R, the absence of a true ring at S, and of a pendent frill at T. The colour, with the exception of the gills, is not unlike that of the mushroom. In determining fungi no single character must be relied upon as conclusive, but all the characters must be taken together. Sometimes a beautiful, somewhat slender, fungus peculiar to stumps in woods is mistaken for the mushroom in *A. cervinus* (Sch.); it has a tall, solid, white, ringless stem and somewhat thin brown cap, furnished

underneath with beautiful rose-coloured gills, which are free from the stem as in the mushroom, and which never turn black. It is

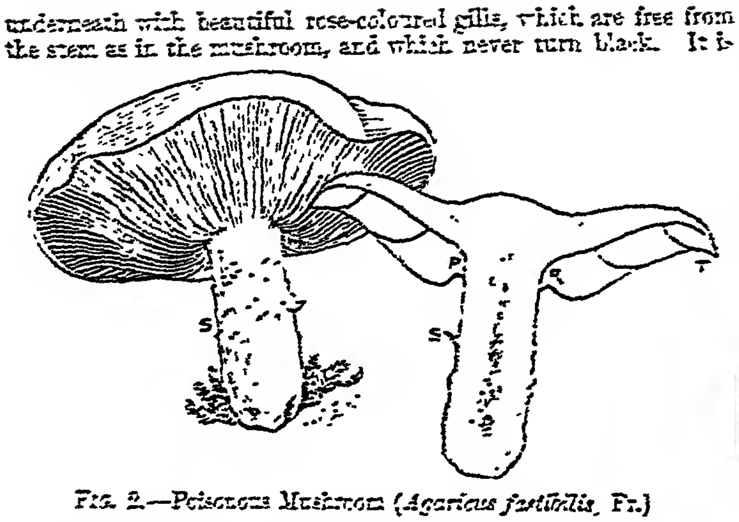

FIG. 2.—Poisonous Mushroom (*Agaricus fastibilis*, Fr.)

probably a poisonous plant, belonging, as it does, to a dangerous cohort. Many other species of *Agaricus* more or less resemble *A. campestris*, notably some of the plants found under the sub-genera *Lepiota*, *Volvaria*, *Pholiota*, and *Psalliota*, but when the characters are noted they may all with a little care be easily distinguished from each other. The better plan is to discard at once all fungi which have not been gathered from open pastures; by this act alone more than nine-tenths of worthless and poisonous species will be excluded.

In cases of poisoning by mushrooms immediate medical advice should be secured. The dangerous principle is a narcotic, and the symptoms are usually great nausea, drowsiness, stupor, and pains in the joints. A good palliative is sweet oil; this will allay any corrosive irritation of the throat and stomach, and at the same time cause vomiting.

The mode of cultivating mushrooms artificially out of doors and in sheds is described under HORTICULTURE, vol. xii. p. 284. Paris mushrooms are cultivated in enormous quantities in dark underground caves at a depth of from 60 to 160 feet from the surface. The stable manure is taken into the tortuous passages of these caves, and the spawn introduced from masses of dry dung where it occurs naturally. In France mushroom-growers do not use the compact blocks or bricks of spawn so familiar in England, but much smaller flakes or "leaves" of dry dung in which the spawn or mycelium can be seen to exist. Less manure is used in these caves than we generally see in the mushroom-houses of England, and the surface of each bed is covered with about an inch of fine white stony soil. The beds are kept artificially moist by the application of water brought from the surface, and the different galleries bear crops in succession. As one is exhausted another is in full bearing, so that by a systematic arrangement a single proprietor will send to the surface from 300 lb to 3000 lb of mushrooms per day. The passages sometimes extend over several miles, the beds sometimes occupying over 20 miles, and, as there are many proprietors of caves, the produce of mushrooms is so large that not only is Paris fully supplied, but vast quantities are forwarded to the different large towns of Europe: the mushrooms are not allowed to reach the fully-expanded condition, but are gathered in a large button state, the whole growth of the mushroom being removed and the hole left in the manure covered with fine earth. The beds remain in bearing for six or eight months, and then the spent manure is taken to the surface again for garden and field purposes. The equable temperature of these caves and their freedom from draught is one cause of their great success; to this must be added the natural virgin spawn, for by continually using spawn taken from mushroom-producing beds the potency for reproduction is weakened. The beds produce mushrooms in about six weeks after this spawning.

The Fairy-ring Champignon.—This fungus, *Marasmius Oreades* (Fr.), is more universally used in France and Italy than in England, although it is well known and frequently used both in a fresh and in a dry state in England. It is totally different in appearance from the Pasture Mushroom, and, like it, its characters are so distinct that there is hardly a possibility of making a mistake when its peculiarities are once comprehended. It has more than one advantage over the Meadow Mushroom in its extreme commonness, its profuse growth, the length of the season in which it may be gathered, the total absence of varietal forms, its adaptability for being dried and preserved for years, and its persistent delicious taste. It is by many esteemed as the best of all the edible fungi found in Great Britain. Like the mushroom, it grows in short open pastures and amongst the short grass of open roadsides; sometimes it appears on lawns, but it never occurs in woods or in damp shady places. Its natural habit is to grow in rings, and the grassy fairy-rings so frequent amongst the short grass of downs and pastures in the spring are generally caused by the nitrogenous manure supplied to the soil in the previous autumn by the decay of a circle of these fungi. Many other fungi in addition to the Fairy-ring Champignon grow in circles, so that this habit must merely be taken with its other characters in cases of doubt.

A glance at the illustration (fig. 3) will show how entirely the Fairy-ring Champignon differs from the mushroom. In the first place, it is about one-half the size of a mushroom, and whitish-buff in every part, the gills always retaining this colour and never becoming salmon-coloured, brown, or black. The stem is solid and corky, much more solid than the flesh of the cap, and perfectly smooth, never being furnished with the slightest trace of a ring. The buff gills are far apart (V), and in this they greatly differ from the somewhat crowded gills of the mushroom; the junction of the gills with the stem (W) also differs in character from the similar junction in the mushroom. The mushroom is a semi-deliquescent fungus which rapidly falls into putridity in decay, whilst the champignon dries up into a leathery substance in the sun, but speedily revives and takes its original form again after the first shower. To this character the fungus owes its generic name (*Marasmius*) as well as one of its most valuable qualities for the table, for examples may be gathered from June to November, and if carefully dried may be

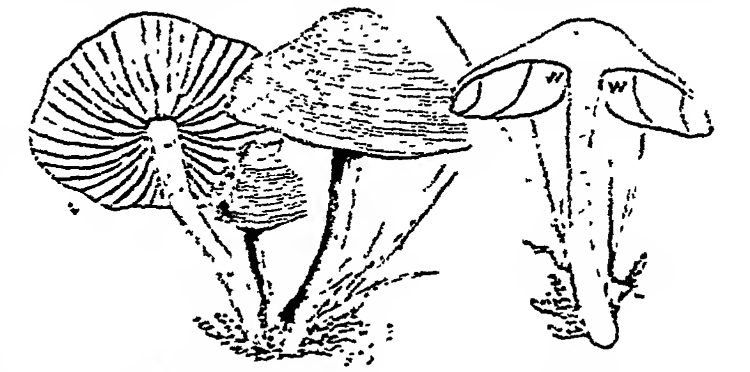

FIG. 3.—The Fairy-ring Champignon (*Marasmius Oreades*, Fr.).

hung on strings for culinary purposes and preserved without deterioration for several years: indeed, many persons assert that the rich flavour of these fungi increases with years. Champignons are highly esteemed (and especially is this the case abroad) for adding a most delicious flavour to stews, soups, and gravies.

A fungus which may carelessly be mistaken for the mushroom is *M. peronatus* (Fr.), but this grows in woods amongst dead leaves, and has a hairy base to the stem and a somewhat acrid taste. Another is *M. urens* (Fr.): this also generally grows in woods, but the gills are not nearly so deep, they soon become brownish, the stem is downy, and the taste is acrid. An *Agaricus* named *A. dryophilus* (Bull.) has sometimes been gathered in mistake for the champignon, but this too grows in woods where the champignon never grows: it has a hollow instead of a solid stem, gills crowded together instead of far apart, and flesh very tender and brittle instead of tough. A small esculent ally of the champignon, named *M. scorodonius* (Fr.), is sometimes found in pastures in Great Britain; this is largely consumed on the Continent, where it is esteemed for its powerful flavour of garlic. In England, where garlic is not used to a large extent, this fungus is not sought for. Another small and common species, *M. porreus* (Fr.), is pervaded with a garlic flavour to an equal extent with the last. A third species, *M. alliaceus* (Fr.), is also strongly impregnated with the scent and taste of onions or garlic. Two species, *M. impudicus* (Fr.) and *M. fœtidus* (Fr.), are in all stages of growth highly fœtid. The curious little edible *Agaricus esculentus* (Jacq.), although placed under the sub-genus *Collybia*, is allied by its structure to *Marasmius*. It is a small bitter species common in upland pastures and fir plantations early in the season. Although not gathered for the table in England, it is greatly prized in some parts of the Continent. Fries, the greatest authority on the higher Fungi, writes: "In Austria in cibariis magni æstumatur." The odour and taste in fungi when raw are often valuable characters in deciding species.

Morel.—This delicious edible fungus, *Morchella esculenta* (Pers.), is more common in Britain than is generally supposed. It grows after warm rains in the spring or early summer in woody places and in orchards and gardens, often in places where the ground has been burnt. Like the champignon, the morel can be easily dried and kept suspended on strings in necklace fashion for winter use. It is generally 3 or 4 inches high, with a hollow stem and a hollow, irregularly globose, honeycombed head, pale buff in colour all over, and furnished with an agreeable odour. There is more than one esculent species of morel: *M. semilibera* (D.C.) is the next best known, but this is rare in Britain. A large species named *M. crassipes* (Pers.)—the *M. smithiana* of Cooke—attains a height of from 9 to 12 inches. This is a fragrant and delicious species, but only suitable for use in a fresh state; it cannot be readily dried. Another valuable edible species is *Gyromitra esculenta* (Fr.), recognized by its brownish-black globose head; it grows amongst firs and is considered rare.

(W. G. SM.)

MUSIC

PART I.—HISTORY.

I. MUSIC[1] is the art which employs sounds as a medium of artistic expression for what is not in the province of literature, of sculpture, of painting, of acting, or of architecture. Whereas literature, whether in verse or prose, describes or states emotions, or perceptions, or impressions; whereas sculpture imitates the outward forms of animated beings, and physiognomically, either in the face, or, to speak more broadly, in the moulding and attitude of the entire figure, displays personal character and the effect of passion upon it; whereas painting vitalizes with colour the forms of sculpture, and extends its range of subjects from animate to inanimate nature; and whereas acting adds speech to the written words of the dramatist, and enforces or even qualifies their meaning by vocal inflexion, and illustrates it by changeful gesture, thus giving the mobility of life to the forms of sculpture and painting;—music embodies the inward feelings of which all those other arts can but exhibit the effect. Those other arts are imitative in respect of their reproducing natural objects or circumstances; it is otherwise with architecture, which makes but conventional reference to nature, and wholly arbitrary application of the lines, the lights, and the shadows of the natural world; and in this particular music has an analogy to architecture which it has not to the other fine arts. In the matter of expression also, architecture may be compared with music in the earlier stages of its development, since representing and also prompting a general idea of solemnity, or grandeur, or gaiety; but music left architecture far behind when, in later times, it assumed the power of special, individual, and personal utterance of every variety of passion. The indefiniteness of musical expression furnishes no argument that music is inexpressive, but is one of the qualities that place it on the highest level of art-excellence, enabling it to suggest still more than it displays, and to stimulate the imagination of the witness as much as to exercise that of the artist. The musician is then a poet, whether we regard the term in its primary sense of "maker," the exact translation of the Greek word by which versifiers were styled in early English, or in its applied sense of one who expresses thought and feeling through the medium of highly-excited imagination. Music, then, is that one of the fine arts which appropriates the phenomena of sound to the purposes of poetry, and has a province of its own in many respects analogous to, but yet wholly distinct from, that of each of the other arts. It is common to style it "the universal language;" but the definition is untrue, for in every age and in every clime there are varieties of musical idiom which are unsympathetic, if not unintelligible, to other generations than those among whom they are first current, and, still more, the very principles that govern it have been and are so variously developed in different times and places that music which is delightful at one period or to one people is repugnant at another epoch or to a different community. An attempt will here be made to sketch the progress of the art through Western civilization, to show how it has been changed from artificial or calculated into natural or spontaneous, and to describe some of the chief forms of its manifestation.[2]

Harmony and melody. To define the special science, and the art which is its application, that is denoted by our word *music*, the Greek language has two other words, *harmonia* or *harmonike* and *melodia*,—*harmonia* implying the idea of "fitting," and so being a term for propriety or general unity of parts in a whole, not in our limited technical sense of *combined sounds*, but with reference to the whole principle of orderly and not specially tonal regulation, *melodia* implying the rising and falling of the voice in speech, and being applied only at a subsequent epoch to a *succession of musical notes*.[3]

We thus owe our three chief musical terms to the Greeks, and in our prevailing system much more besides; they themselves, however, owed all to earlier sources, for the essentials of their knowledge and practice are traced to Egypt.

Origin. It has been ingeniously suggested and well sustained by Mr. J. F. Rowbotham that in prehistoric times music passed through three stages of development, each characterized by a separate class of instrument, and the analogy of existing uses in barbarous nations tends to confirm the assumption. Instruments of percussion are supposed to be the oldest, wind instruments the next in order of time and of civilization, and string instruments the latest invention of every separate race. The clapping of hands and stamping of feet, let us say, in marking rhythm exemplify the first element of music, and the large family of drums and cymbals and bells is a development of the same principle. Untutored ears are quicker to perceive rhythmical accentuation than variations of pitch, so the organ of time makes earlier manifestation than the organ of tune, though, musical sound being a periodic succession of vibrations, the operation of the latter is truly but a refinement on that of the former. The sighing of wind, eminently when passing over a bed of reeds, is Nature's suggestion of instruments of breath; hence have been reached the four methods of producing sound through pipes:—by blowing at the end, as in the case of the English flute and the flageolet; at the side, as in that of the ordinary concert flute; through a double reed, as in that of the hautboy or oboe and bassoon; and over a single reed, as in that of the clarionet—all of which date from oldest existing records; and also upon the collection of multitudinous pipes in that colossal wind instrument, the organ. An Egyptian fable ascribes the invention of the lyre to the god Thoth; a different Greek fable gives the same credit to the god Hermes; and both refer it, though under different circumstances, to the straining of the sinews of a tortoise across its shell,—whence can only be inferred that the origin of the highest advanced class of musical instruments is unknown. This class includes the lyre and the harp, which give but one note from each stretched string; the lute, which, having a neck or finger-board, admits of the production of several notes from each string by stopping it at different lengths with the fingers; the viol, the addition of the bow to which gives capability of sustaining the tone; and the dulcimer, finally matured into the pianoforte, wherein the extremes of instrumental fabrication meet, since this is at once a string instrument and an instrument

[1] From the Greek μουσική; but this included all arts and sciences over which the Muses presided—the encyclopædia of learning. The science of sounds was particularly involved in that of the stars, and hence the word had special reference to these two in their relation to numbers; and in its comprehensive sense it was employed to denote the entire mental training of a Greek youth. In Latin the word had a more restricted meaning.

[2] William Chappell's *History of Music* is the authority for the correction of errors in the works wherein the history and theory of Greek music were first treated in modern times, errors that have been repeated by intervening writers; and it is the authority for explanation of Greek technicalities that are misrepresented in Latin translations, and falsely understood in our own day.

[3] *Harmonia* had a special signification with the disciples of Pythagoras, who used the word in place of *enharmonia*, of which more hereafter.

of percussion, having the hammer of the drum to strike the string of the lyre.

Intervals. Musical intervals are named numerically from any given note, say C as the 1st, the note next to which is thus D the 2d, the one beyond is E the 3d, and so on to another C, the 8th. Beyond the 8th, numerical names are only used for the rare combinations of the 9th, the 11th, and the 13th. This is because the 8th is in some sense a reproduction of the 1st, as all intervals beyond it are reproductions of the 8th below them—reproductions, that is, uniting identity and difference, the relation of tones in the higher octave being just what it is in the lower, while each tone is so or so much more acute than its under 8th, an analogy to which may be sought in the reduction of any visual object to half its size while all its proportions are preserved, the larger and the smaller, as in the interval of the 8th, thus uniting identity with difference. When two voices or instruments produce the same sound they are in unison; the unison or 1st[1] is styled perfect; so too is its reproduction, the 8th; the 8th is unequally divisible into a 5th and a 4th, and these two are classed with the 1st and 8th as perfect. There are many specialities that distinguish the four perfect intervals in music from every other. The two notes of which each is constituted are, save in one instance, of the same quality—as natural, or sharp, or flat; to raise or lower either of the two notes by a chromatic semitone[2] changes a perfect interval into a discord, whereas the other intervals are elastic, that is, they may be major or minor from having a chromatic semitone more or less in their extent, and are not changed from concords to discords, or the reverse, by the modification. To invert a perfect interval by placing the higher note beneath the lower produces another perfect interval, whereas to invert any of the other intervals reverses its character of major or minor. The progression of two parts together from one to another 1st or 8th, from one to another 5th or 4th, has, save in exceptional instances, the bad effect that all musical grammar forbids, whereas the progression of two parts in 3ds or 6ths with each other has a good effect. In the resolution of fundamental discords the progression of perfect intervals is free, whereas that of the imperfect intervals is restricted; and further, in the relation of subject and answer in a fugue, one perfect interval may be changed for another, but never for an imperfect interval. Many technicalities are anticipated in the foregoing which can only be explained in the sequel, but present mention of them is unavoidable in reference to a position now to be stated. The Egyptians perceived the distinction of the perfect intervals from others, if not all the above specialities, and regarded them as typical of the seasons, spring bearing the proportion of a 4th to autumn, of a 5th to winter, and of an 8th to summer. The distinction, then, has been observed for many centuries, but neither ancients nor moderns have adduced any explanation of the phenomenon, and the wondrous fact that perfect intervals differ in constitution and treatment from other intervals appears to defy reason, and not even to incite speculation.

Analogy to astronomy. The anciently supposed affinity of music to astronomy was taught by Pythagoras (585 B.C.), who derived the notion from the Egyptians, and exemplified it by comparison of the lyre of seven strings with the planetary system. The Sun, then believed to rotate round the earth, was deemed the chief planet, next to which were, on the one side Mercury, Venus, and the Moon, and on the other side Mars, Jupiter, and Saturn. The strings of the lyre, not the notes they sounded, were thus named:—Mesē (middle), being the principal or keynote, corresponding with our A on the fifth line with the bass clef, and likened to the Sun; Paramesē (next to middle) or B flat, likened to Mercury; Paranētē (next to lowest, *i.e.*, shortest = highest in pitch) or C, likened to Venus; and Nētē or Neatē (lowest) or D, likened to the Moon; these constituted the upper tetrachord or scale of four notes, to which the lower tetrachord was conjoined by having Mesē for its acutest note, which was the gravest of the other tetrachord; next to it was Lichanos (forefinger string) or G, likened to Mars; then Parhypatē (next to highest, *i.e.*, longest = lowest in pitch) or F, likened to Jupiter; and lastly Hypatē (highest) or E, likened to Saturn. The Moon being of all the planets the nearest to, and Saturn the farthest from, the earth, they are analogous to the shortest and the longest string.

Greek lyre. The Greek lyre (see LYRE, vol. xv. p. 113) had at first four strings, to which subsequently were added the longest three; then an 8th, corresponding with our E, tuned to an 8th above Hypatē; then three below the latter, which took the scale down in pitch to B on the second line with the bass clef; afterwards three above the former, which took the scale up to A in the second space with the treble clef; and finally Proslambanomenos, corresponding with our A in the first space with the bass clef, extended the "greater system" of fifteen notes to an 8th below Mesē and an 8th above it.[3]

Pytl rean tem. Tradition has it that Pythagoras made his discovery of the ratios of the perfect intervals by listening to some smiths who struck the iron on their anvil with hammers of different weights, and thus produced different notes from the metal. But the narrator of the tale has disregarded the obvious fact that, save for slight variation due to the greater or less heat of its different parts, a metallic bar, like a string, always sounds a note of the same pitch whatever be the weight of the instrument with which it is struck.[4] The smithy wherein Pythagoras worked his musical problems was the land of Egypt, where he is said to have acquired and whence he imported his knowledge. His division of the 1st and 2d degrees and the 2d and 3d degrees of the tetrachord, counting downward in pitch into equal intervals of a major tone, left but a *leimma* (remnant), which was less than a semitone between the 3d and 4th degrees. Aristoxenus (300 B.C.), who has been called the father of temperament, discovered the difference between the major and minor tones, the first having the ratio $\frac{9}{8}$, and the second having that of $\frac{10}{9}$. His followers formed a school opposed to that of Pythagoras, and there was severe contention between the two. Subsequent theorists disputed whether the major or the minor tone should be above the other, and it was Claudius Ptolemy (*c.* 150 A.D.) who enunciated that the major tone should be below the minor, which is the principle that directs the intonation of our present scale. This intonation may account for the difference between the effect in proceeding from the minor chord of the supertonic to the major chord of the tonic, and the effect in proceeding from the minor chord of the submediant to the major chord of the dominant, of which the latter, at the interval of a minor tone, is acceptable and the former, at the interval of a major tone, is repugnant to cultivated ears.

---

[1] Literally, the 1st is not a musical *distance*; but, as it is a frequent combination in counterpoint, and as its repetition is not rare in melody, it is conveniently classed as an *interval*.

[2] A chromatic or minor semitone is between two notes of the same alphabetical name, as C and ♯C, or D and ♭D; a diatonic or major semitone is between two notes of different alphabetical names, as C and ♭D, or C and B; the ratio of the latter is $\frac{16}{15}$, and that of the former varies with the place of the interval in the chromatic scale.

[3] Terpander (700 B.C.) was the first of whom it is said that "he added a new string to the lyre," but the ascription to him was probably figurative and not literal, for the proverbial expression was applied to any one who discovered a novelty in science or excelled in art.

[4] Not only was this manifest fiction repeated from age to age, but it was transferred from the ancient philosopher to Handel by a writer of some sixty years since, who assumed that the composer derived a melody from the various sounds of smiths' hammers on one piece of iron.

Greek modes.

The Greeks had four modes or scales included in their "greater system." The Dorian comprised a series of eight notes from D to D, of which ♭B was the 6th, and had its semitones between the 2d and 3d and the 5th and 6th degrees counting upward. The others were exact transpositions of this, as all our modern scales are transpositions of the scale of C, the identity of intervals being induced by the various tuning of the lyre strings. The Phrygian mode lay between E and E, and had ♯F and ♮B, the Lydian between ♯F and ♯F had ♯G and ♯C, and the Mixo-Lydian between G and G had ♭B and ♭E. These four were styled *authentic*, and were distinguished by having the dominant (or predominant note) at the interval of a 5th above the tonic. Each had a *plagal* or relative mode at the interval of a 4th below the authentic, distinguished by having the dominant a 4th below the tonic, and defined by the prefix "hypo" to the name of the authentic mode, as Hypo-Dorian beginning on A, Hypo-Phrygian on B, &c. To each mode was assigned its special character of subject, which may be accounted for by the different qualities of voices that could sing in lower or higher keys, the majestic being fitted to a bass, who would sing in the Dorian, the tender to a tenor, who would sing in the Lydian, and so forth. In later but still classic times other modes were added to these, but on the same principle of precise notal transposition.

Greek genera.

The tetrachords above described—having a semitone between the lowest note and that next above it, a tone between the 2d and 3d, and a tone between the 3d and 4th, the latter of which Ptolemy made smaller than the other, and so left a semitone between the 2d and 1st degrees—were called *diatonic*, as A, ♭B, C, D. To lower by a semitone the 2d note from the highest produced a *chromatic* tetrachord, as A, ♭B, ♮B, D. To tune the 2d string from the top yet a semitone lower reduced it to the same pitch as the 3d string, which was equivalent to its total rejection, and this form of tetrachord was the *enharmonic*, the invention of which was ascribed to Olympus (640 B.C.). If we observe the two tetrachords that occur, for instance, in the Dorian mode—that from D down to A, and that from A down to E—with the addition of the tonic D below, it will be seen that our modern scale of D minor with the omission of the 4th and 7th degrees was in the enharmonic genus, and that the chromatic genus gave the minor and major 3d and the minor and major 6th with still the omission of the 4th and 7th:—enharmonic, D, E, F, A, ♭B, D; chromatic, D, E, F, ♯F, A, ♭B, ♮B, D; and the other authentic modes were transpositions of this. In the harmonic scale of nature the 7th from the generator is too flat, and the 11th (octave above the 4th) is too sharp, for accepted use; the rejection of these two notes indicates a refinement of ear that shrank from the natural and equally refused the artificial intonation of these degrees of the scale. Mr. Carl Engel proves the rejection of the said 4th and 7th from the keynote by nations of high civilization in remote parts of the world; we call a scale that is so formed Scottish, but in China, Mexico, and other places than Great Britain the same arrangement is found to have prevailed in the remotest periods of which we have knowledge. An important principle is here involved which has affected all musical theory directly or indirectly, and is now seen to lie at the foundation of modern rules of harmony or the combining of musical sounds. The Pythagoreans advocated the use of the Enharmonic genus, and so received the appellation of Enharmonicists, or were as often called Harmonicists, and hence the twofold application of the term "harmonia."

Antiphony.

Anacreon (540 B.C.) sang to the accompaniment of the magadis (doubling bridge), an instrument imported from Egypt to Greece; it had a bridge, across which the strings were drawn at one-third of their entire length, when of course the shorter division sounded the note an 8th higher than the longer. Aristotle (384 B.C.) describes *antiphon* (τὸ ἀντίφωνον) as the singing of a melody by men an 8th lower than it is sung at the same time by boys—in other words, what is miscalled in modern church congregations "singing in unison." The same writer enunciates that the antiphon may not be at either of the other perfect intervals, the 5th or the 4th below a melody, and in this he anticipates a rule till lately deemed inflexible in modern music. Beyond these two instances of the combination of the 8th, no allusion has been found in ancient writings to the use of harmony in the modern sense of the word, and the only three examples of ancient Greek music that are known to exist are melodies (notes in succession), and supposition assigns them to the 3d or 4th century A.D. They are hymns to Apollo, Nemesis, and Calliope, with the respective verses, and their translation into modern notation has only been possible through reference to the verbal accent, because there are no extant rules of that era for purely musical measure. Nevertheless we have Egyptian paintings of the period of Dynasty IV., and Greek sculptures of players on pipes of different lengths which must have produced notes of different pitches, and sometimes in the same party players on string instruments with necks whereon two strings, differently stopped and yet sounded together, would have yielded a combination of different notes; and this, though a speechless, is a strong evidence that the musicians so represented made at least a forecast of modern harmony. One cannot but marvel that, while copious treatises have come down to us upon niceties that have here been adduced, nothing has been brought to light but pictorial testimony as to ancient knowledge of chords; and the three specimens just mentioned are all that have been found of musical composition in any form.

Greek application of music.

The classic Greeks used music in rhapsodizing or chanting with vocal inflexions the epic poems; they employed it in religious rites and to accompany military evolutions; and prizes were awarded for its performance by voices and on instruments (including, during the last two centuries B.C., the organ) at their Olympic and other games. It belonged essentially to the drama, which had its origin in the dithyrambic hymns; these were gradually developed into the tragedy, which took its name from the tragos (goat) that was sacrificed to Dionysus during the performance. Possibly Thespis (536 B.C.) may have spoken the recitations with which he was the first to intersperse the hymns; but some interpreters of Greek writings affirm, and others while doubting do not disprove, that in the mature drama all the characters sang or chanted, seemingly after the manner of the rhapsodists, and the impersonal chorus sang to instrumental accompaniment during their orchestric evolutions, from which motions or marchings the part of the theatre wherein the chorus were stationed between the audience and the proscenium was called the orchestra. Here, then, was the prototype of the modern opera, the main departure from which is the transplanting of the chorus to the stage and giving to its members participation in the action. Æschylus wrote the music to his own tragedies, Sophocles accompanied on the cithara the performance of his *Thamyris*, if not of other of his plays; Euripides left the composition of the music for his works to another genius than his own, and such was the case with after dramatists.

Roman theatrical music.

In ancient Rome the choristers in tragedies were very numerous, including female as well as male singers; they were accompanied by a large number of instruments, among which trumpets were conspicuous. This we learn from Seneca, who employs the idea of multitudinous unity it presents to illustrate figuratively the organization of a state.

Ambrosian music. How or when the musical system of the Greeks fell into disuse is still untraced; certainly it prevailed and engaged the attention of philosophers for some centuries of the Christian era. The first notices of music in the Western Church refer to the manner but not to the matter of the performance. The name of St Ambrose (384 A.D.) is familiarly associated with the music of his metropolitan church in Milan; but all that is proved of his connexion with the art is that, advised by Flavian of Antioch, he adopted for the first time in the West the practice of dividing the verses of the Psalms between responsive choirs, an usage which has a natural connexion with the so-called "parallelism" of Hebrew poetry, indicated in the English version of the Psalter by the colon that divides each verse. This practice has come to be falsely called antiphonal singing—falsely, because, according to the etymology of the word and to Aristotle's definition, the Greeks used it for singing *together*, whereas the church uses it for singing in *alternation*. St Ambrose regulated the order of the prayers, the ritual, and other matters in the service besides the music; his ordinances prevailed in Milan, and were distinguished by his name; so the term Ambrosian denotes the "use of Milan" in all things in which that differs from the practice of other churches. No proof is given that the melodies so defined belong to the date of St Ambrose.

Errors of Boetius. Boetius (475 A.D.) was the most copious of the Roman writers on music, but his voluminous treatise *De Institutione Musica* proves that the Greek principles of the art had in his time become matter of antiquarianism; nay, it proves further that he did not understand the technical terms he professed to translate. For instance, he mistook the word for the shortest string of the lyre (Nētē), which naturally gave the acutest sound, to signify the gravest note; and he mistook the word for the longest string (Hypatē) to signify the acutest note. It is not necessary here to catalogue this author's many verbal errors;[1] but it is important to mention that he ignored the advance nade by Didymus and completed by Ptolemy in the tuning of the scale with the major and minor tones, and the modern semitone of $\frac{16}{15}$, counting upward, and returned to the Pythagorean division of two major tones, inducing a discordant 3d, and the leimma $\frac{256}{243}$.[2] The very eminence of Boetius makes it matter of regret that he ever wrote upon music. His Latin book being accessible when those of Greek authors were not, it was established as a text-book on the art in the English universities, and musical degrees were granted for knowledge of the principles it set forth; musical progress was thus seriously retarded, and the 18th century was far advanced before search for sound theory dispelled reverence for his scholastic dogma.

Gregorian music. As St Ambrose ordained a ritual for Milan which bore his name, so also St Gregory the Great (590 A.D.) ordained one for Rome which was called Gregorian. The terms Ambrosian and Gregorian are now erroneously applied to a system of music that came first into use centuries after the dates of the two bishops, and they are applied even to melodies constructed upon that system. This sentence of St Isidore, the friend and survivor of Gregory, distinctly proves that no music of the time of the Roman pontiff was or could be preserved: "Unless sounds are retained in the memory, they perish, because they cannot be written." Whatever the age of the oldest church melodies, belief cannot associate them with the days of St Gregory.

[1] See Chappell, *op. cit.*

[2] The ratios of the three may thus be stated with reference to modern notation, the last being the temperament now in use:—

	C	D	E	F
Pythagoras . . .	576	648	729	768
Didymus . . .	576	640	720	768
Ptolemy . . .	576	648	740	768

Notation. The system of notation by letters of the Greek alphabet had fallen into disuse. A system by neumes (πνεῦμα) or pneumata, of later date than St Gregory, employed signs over or under the syllables to indicate the rising or falling of the voice but not to define its extent, and, in the manner of modern punctuation, to show where breath should be taken. This was followed by, though for a time practised coincidently with, one in which the Roman letters stood for notes. Afterwards, something like our staff was employed, of which the spaces only and not the lines were used, the syllables being placed in the higher or lower of them to denote to what extent the melody should rise or fall. Of earlier date than anything that has been found of like advance in other countries is a service-book which belonged to Winchester cathedral, and contains music written on the lines as well as in the spaces of a staff of four lines; and this comprises a prayer for Ethelred II., who died in 1016. It has been stated and constantly repeated that staff notation was invented by Guido, a monk of Arezzo, who was alive in 1067, and whose book, *Micrologus*, refers only to writing in spaces, and who throughout his works professes no more than to describe established principles, and these far less advanced than what then prevailed in England. To him is falsely ascribed the first use of a red line for the note F, and a saffron for the note C, and to him, as unduly, the appropriation of the initial syllables—nonsense without the completion of the words—of six lines of a hymn to St John the Baptist as names of the notes—Ut, Re, Mi, Fa, Sol, La.

Scale Hucbald (930 A.D.) invented a system, not of notation, but of scales, wherein the semitone was always between the 2d and 3d of a tetrachord, as G, A, ♭B, C, so the ♮B and ♯F of the second octave were in false relation to the ♭B and ♮F of the first two tetrachords. To this scale of four notes, G, A, ♭B, C, were subsequently added a note below and a note above, which made the hexachord with the semitone between the 3d and 4th both up and down, as F, G, A, ♭B, C, D. It was at a much later date that the 7th, our leading note, was admitted into a key, and for this the first two letters of the last line of the above-named hymn, "Sanctus Johannes," would have been used, save for the notion that as the note Mi was at a semitone below Fa, the same vowel should be heard at a semitone below the upper Ut, and the syllable Si was substituted for Sa. Long afterwards the syllable Ut was replaced by Do in Italy, but it is still retained in France; and in these two countries, with whatever others employ their nomenclature, the original Ut and the substituted Do stand for the sound defined by the letter C in English and German terminology. The literal musical alphabet thus accords with the syllabic:

A	B	C	D	E	F	G
La,	Si,	Ut or Do,	Re,	Mi,	Fa,	Sol.

In Germany, however, a remnant of Greek use prevails in having the note above A at the interval of a semitone, namely ♭B, as was the classical Paramesē above Mesē, and the Teutons employ the 8th letter H to denote the sound we call ♮B, and the Italians and French Si. **Gamut** The gamut, which, whenever instituted, did not pass out of use until the present century, regarded the hexachord and not the octachord, employed both letters and syllables, made the former invariable while changing the latter according to key relationship, and acknowledged only the three keys of G, C, and F; it took its name from having the Greek letter gamma with Ut for its lowest keynote, though the Latin letters with the corresponding syllables were applied to all the other notes.

Ecclesiastical modes A system of modes had already been established for ecclesiastical music which differed essentially from the Greek modal system in having no notes inflected by sharps

or flats, and consequently a different distribution of tones and semitones in each mode from that in all the others. The sole exception from this was the permissible ♭B in the second octave, the toleration of which was for the sake of avoiding the interval of the augmented 4th between ♮B and F below it, but the inflected note was admitted in the fifth mode only. Here the numbers of the modes must be explained and the later misapplication to them of the Greek names. The two classic forms of authentic and plagal were employed in the structure of melody, that having its dominant above the tonic or final, this having its dominant below it. The four authentic modes bore the uneven numbers—first beginning its scale from D, third from E, fifth from F, wherein the ♭B might be used, and seventh from G. The four plagal modes bore the even numbers, which showed their parallelism or relation to their respective authentic modes—second beginning from A, fourth from B, sixth from C, and eighth from D. In the latter half of the 9th century, Notker, abbot of St Gall, applied the Greek names to these, regardless of the distinction that by use of inflected notes the classic modes had all the same disposition of tones and semitones, whereas by the omission of sharps and of flats the church modes varied from each other in the arrangement of intervals. The confusion of F for the church Lydian with ♯F for the Greek Lydian is obvious, and the reader may easily trace the discrepancies between the systems if he consider the diverse principles on which the two are based. Some centuries later, the ninth and tenth modes, Æolian and Hypo-Æolian, beginning respectively on A and E, were added, and later still, the eleventh and twelfth, Ionian and Hypo-Ionian, beginning respectively on C and G. The mode or scale that comprised ♭B was called *mollis*, and those which had ♮B were each called *dura*, and hence the sign "♭" to indicate a flat, the word *bémol* to define the same in French, the word *be* or its first letter to name a flat, and the terms *moll* and *dur* to express minor and major in German. Lastly, as bearing on the aversion from the augmented 4th between F and B, and on the omission of the 4th and 7th in several characteristic national scales, it must be added that, whenever the 5th above or 4th below a tonic or final was B, C instead of this note was dominant of the mode.

Harmony originated by Northern peoples. Coincidently with the church practice of constructing unrhythmical melody in one or other of these unnatural and arbitrarily devised modes, and of singing the same without accompanying harmony, the people of Northern nations had the habit, as has been proved in many districts, of singing tunes with the accompaniment of different parts performed by other voices. Among what tradition has preserved of these tunes, some indeed are in one or other of the church modes, as was inevitable in the productions of people who had experience of this artificial system in the music of the daily service; but many approximate far nearer to the scale of present use, and are thus susceptible of just harmonic treatment, which is incompatible with the modal system. So devoted to their song-tunes were the English people in the later Saxon times that churchmen, as is well attested, would often sing these to attract the public to divine worship, and after the Norman settlement it was a frequent custom to write words of hymns to fit secular tunes, which tunes and their titles are preserved through this appropriation only, with the Latin words written under the notes.

Descant. The appropriation of popular tunes to church use was followed by the adoption of the harmonic practice or part-singing of the people in many English districts, and probably in other Northern lands. At the end of the 11th or beginning of the 12th century, a part added to another received the name of *descant* (*dis-cantus*, something apart from or extra to the song), and rules were gradually framed for its extemporaneous invention. It was preceded by *faburden* (the singing of a single note or drone throughout a given melody), and this latter term was retained with a wider contrapuntal signification, whence difficulty has arisen as to its primary meaning. To "bear the burden" was to sing the bass below either a single part or fuller harmony; when the bass was a single note, which was of course the tonic, this being generally F or Fa, it constituted the faburden or drone; that the term is translated *fauxbourdon* and *falsobordone* in French and Italian may have referred at first to its being a single note or drone, and not a part changing with the changeful harmony. Faburden.

Diaphony. The assertion that previously to the period now being considered there prevailed a church custom of accompanying melodies with a transposition of the same at the interval of the 5th or 8th above or below is disproved by Aristotle's injunction that the antiphon might be at the 8th below, but not at any other of the perfect intervals, and the blundering of Boetius could not eradicate the fact, though it might obscure the rule. It is also disproved by the habit of the peoples of the North to sing in harmony, showing unschooled perception of the principles of combining sounds, and making it impossible that either they or their priests (who must casually have heard their natural performances) could have tolerated the cacophonous progression of parts at perfect intervals from each other. It is disproved by the identity of human perceptions to-day with those of a thousand years ago, and by the certainty that men of old positively could not have sung with satisfaction, or heard with respect, things that are in the highest degree offensive to us all. An explanation may be speculatively ventured, that the manuscripts wherein two parts appear to be written in 5ths or 4ths with each other are not scores showing what was to be sung in combination, but the parts for separate choirs, showing what was to be sung in response; thus, when $\left\{\begin{matrix} D \\ A \\ D \end{matrix}\right\}$ stand as the initials of three melodies, the top or the bottom may have been intended to be sung alone, the middle to follow, and the other to succeed. In this is to be seen the *germ* of the fugue, if we may suppose that the part which first held the cantus was continued in descant, when the cantus was sung a 5th higher by another part. Music written as here described is defined as *diaphony*,—a term at least as appropriate to the successive as to the simultaneous singing of a melody at the interval of a 5th above or below.

Musical measure. One of the most inscrutable things to the modern student is the lateness at which notation was devised for defining the relative length of musical sounds. The rhythmical sense is the earliest of the musical faculties to be developed, and is often the strongest in its development among individuals and nations. Still, the ancients have left no record that they had signs of indication for the length of notes, and centuries rolled over Christendom before there was any chronicled attempt to find a principle for supplying this musical necessity. Here again conjecture will insist that the practice of singing longer and shorter notes with stronger and weaker accent must have prevailed before a system was framed for its regulation; and in this supposition offers that the instincts of the people must have given example for the canons of the schoolmen. Franco of Cologne, in the 12th century, is the first writer who codified the uses of "measured music," and all he enunciates is expanded in the treatises of Walter Odington, a monk of Evesham who was appointed archbishop of Canterbury in 1228. At this period and after-

wards, bar-lines were drawn across the whole or a portion of the staff to show the end of a musical phrase in accordance with that of the line or verse which was to be sung to it, and the number of notes between these bar-lines was more or less, according to the number of syllables in the verse. It was not, however, till more than three hundred years later that music was first divided into bars of equal length, and not until a still later date that these were applied to their most valuable purpose of showing the points of strongest emphasis. Prior to this invention the distribution of accent was styled *perfect* or *imperfect time*, according to whether the strongest note was to be the first of three or the first of two, or according to whether three or two should follow during the continuance of one, corresponding with present division into triple or duple time. Our compound times were denoted by such directions as "imperfect of the first and perfect of the second," which may be translated by our sign $\frac{6}{4}$ or $\frac{6}{8}$, meaning that a bar is divisible into two equal notes (dotted minims or dotted crotchets), and each of these into three equal notes (crotchets or quavers). It is not only that early music is, on account of this vague notation, difficult to interpret, but writers seem to have had undefined notions of where their accent should lie; and hence we have varying versions of melodies, partly because the transcribers may have doubted how to express them, and partly because composers, when choosing them as themes against which to construct other parts, lengthened or shortened any of the notes at the prompting of their own fancy. It was not until the 18th century that the plan was fully accepted of having the strongest note on the first of every bar, and of having, with rarest exceptions, the close or cadence or conclusion of every phrase on this note of strongest accent. To induce such termination of a phrase many a strain must begin with a half bar, or with a shorter or longer fragment, and the exceptions from the rule are so few as to be easily mastered, and so clear as to aid in strengthening the principle.

Motet and anthem.

Descant, which has become a term of general use for disquisition on a stated subject, has been shown to owe its first meaning and musical application to the words *discantus*. A like meaning belongs to the word *motet*, which seems to have come from *motetus*, to denote a florid or moving part against a fixed theme in longer notes.[1] It may be supposed that the term anthem had reference originally, similarly to the word motet, to a free part constructed against or upon the plain-song. The word descant has passed out of use as a musical definition; motet now generally signifies a composition to Latin text for the Roman Church, and it is also applied to the works produced in North Germany in the centuries next following the Reformation which were elaborations of the choral melodies; and anthem is applied to pieces designed for use in the Church of England.

Counterpoint.

When descant ceased to be improvised, and with the advance of notation the writing of a carefully-planned accompanying part became more and more practicable, such a part was defined as *counterpoint*—point or note against note. Counterpoint is simple when each melody is in notes of the same length as those of an accompanying melody; it is florid when one melody proceeds in longer or shorter notes than another melody. At first the use of perfect concords only was allowed in counterpoint, but of these never two at the same interval, as two 5ths or two 8ths, in succession. 3ds and 6ths were afterwards introduced. Then discords were admitted under either of two conditions: (1) that they were approached and quitted by step and not by leap, and were always unaccented; (2) that they were suspended from a note of a previously-sounded chord, or from a note without harmony, and that they were resolved by passing to a concord while the harmony lasted against which they were discordant. Subsequently one more class of discords was employed; these were elements of the harmony, being added to, not substituted for, the notes of a chord, and they were resolved, with the change of the entire chord, upon notes of that chord whose root was at the interval of a 4th above the root of the discord. It is from the institution of the art of constructing counterpoint that the history of the music we know, and the capability to produce it, are truly to be dated. Throughout the period of transition from what must be regarded as an instinct of the people to what was truly a scholastic problem, there were English writers on music in such numbers as to prove the high consideration in which it was held in Britain, and the great pains spent there to evolve principles for its regulation.[2] John of Dunstable is especially to be noted, of whom Tinctor the Netherlander (*c.* 1460 A.D.) wrote, in discussing the art of counterpoint: "Of this new art, as I may call it, the fountain and source is said to have been among the English, of whom Dunstable was the chief." Contemporaneous with Dunstable, but far behind him in esteem, was Egide Binchois, a musician of Picardy.

Canon and Round Catch.

The first essays at composition in harmony were in the form of *canon*—that is, in which successive parts have the same melody, but begin each at a stated period after its precursor. When the first part completes a rhythmical sentence prior to the entry of the second part and continues the melody as accompaniment to the second, and so on with regard to the third or fourth parts if there be so many, the composition has in England always been styled a *round* or *catch*, as distinguished from the closer canon, in which the successive parts enter without regard to the close of a phrase; but elsewhere than in England no distinction is made between the catch and the canon. The term round refers to the return to the beginning by the first part, while the other parts respectively continue the melody. The term catch springs from each later part catching up the tune during its continuance by the others. The term canon relates to the problem of finding the one or more points in a melody whereat one or more successive parts should begin the same tune. Very early allusion is made to the singing of catches by the English people, which continued in practice until after the Restoration; every trade had its characteristic catch; there were many on pastoral subjects; those which engaged composers in the time of Charles II. are mostly of a bacchanalian cast; and the form was appropriated in the later Georgian era to sentimental subjects, when the practice of singing catches had passed from the people at large, but was preserved in some convivial clubs that consisted of men of fortune, who paid and listened to, but took no part with, professional singers.

Fugue

Quite distinct from the canon is the *fugue* (*fuga*). In it a short complete melody *flies* (hence the name) from one part to another, while the original part is continued in counterpoint against it. To suit the different compass of high and low voices, this melody is transposed into the key of the dominant (the 5th above or 4th below) when assigned to the second entering voice; in the first instance it is called the *subject* or *dux*, in the second it is called the

[1] Among other grounds for this derivation a strong one is that in the 13th and 14th centuries the word *motetus* often defined a florid part next above that which was styled *tenor*, because it *held* the chief melody, the word *motetus* being subsequently changed for *medius* or *mean* when that part stood midway between the *tenor* and the third part above it or *treble*. Bass, or base of the harmonic column, was then designated the *burden*

[2] John Cotton (referred to as Johannes Anglicanus by the almost fabulous Guido) was the earliest to indicate the good effect of contrary motion between two simultaneous melodies

answer or *comes*, and they were formerly also distinguished as masculine and feminine. A subject is *real* when it admits of exact transposition into the key of the dominant; it is *tonal* when it needs modification to be fitted for this change, and then, if authentic, its answer must be plagal, and, if the subject be plagal, the answer must be authentic. The copious rules of fugal development needed many years for their ripening, but the beginning of this art-form dates from very primitive times, and a speculation has been already offered as to its origin (p. 81).

Priority of English music.

The earliest piece of music for several voices that has been found in any country is an English "six men's song," contained in a manuscript which best judges assign to the period prior to 1240. It is a canon for four voices, with independent parts for two more, which stand as a foot, or burden, or ground bass to support all the others. The original words are a description of summer; these are proof of the secular origin of the music, but there are also written to the notes the words of a Latin hymn, which prove the practice above noticed of utilizing the people's songs for church purposes. The Arundel MS., which had lain unnoticed in the library of the Royal Society and has lately been transferred to that of the British Museum, comprises several compositions in two-part and three-part counterpoint, and it belongs to the year 1260—a new addition to the many proofs of the earlier and greater advance of music in England than in other countries. In the Parisian library are some pieces by Adam de la Hale, the Hunchback of Arras, which consist of a secular tune as bass with its original words, and two florid parts above it with sacred Latin words. The reputed author lived in the later half of the 13th century, but it is surmised that the contrapuntal parts may have been added to his tune at a subsequent period by another hand; if this be so, the English pieces are the first, and seem to be the only extant specimens of counterpoint of the period.

Flemish school.

Thus far the advance of music was earlier and greater in England than elsewhere. In the 15th century Flanders produced the musicians of most esteem and greatest influence. Early among these was Ockenheim or Ockeghem of Hainault (*c.* 1420-1513), who was surpassed in fame by his pupil Josse Després (more commonly known by what must have been his pet name of Josquin) of Hainault. He practised the art in his own country, in Italy, in France, and in Austria, and was everywhere regarded as its highest ornament. Though not credited with the origination of principles, he is highly extolled for his practical application of those already acknowledged, and the renown of many of his scholars shows him to have been as good a teacher as he was a voluminous composer. In his works, however, the artificiality of the prevailing style is obvious; many of them have some secular song for "cantus fermus" which supports the florid melodies set to sacred texts that it was the musician's highest aim to engraft upon them. Some of them are notable for a pleasantry or even a jest framed on a punning application of the names of the notes, or on the choice of a text that was pertinent to the occasion for which they were written. Others are distinguished for the multiplicity of their parts. All are of a character to elicit admiration of their ingenuity rather than induce delight by their beauty.

Conservatories academies.

Tinctor, already mentioned, founded in Naples the first musical conservatory, and coincidently Willaert, another Fleming, founded one in Venice, their object being, as implied in the definition, to conserve the art of music from corruption. Not only in these exclusively musical schools and in similar institutions which sprang up in the same and other cities was the art cultivated, but in the academies of general learning that were established in all the Italian cities when study of the classics became the passion of the age there was generally provision for the teaching of music.[1]

In the 15th century and later, because musical erudition was still applied entirely to the service of the church, and because Italy was the ecclesiastical centre, musicians of all lands went to Italy, and especially to Rome. It was, however, in England first, and it has been only in England until America adopted the practice, that academical honours have been given to musicians. John Hamboys (*c.* 1470), author of some treatises on the art, is the reputed first doctor of music. The record exists that in 1463 the university of Cambridge conferred the degrees of doctor and bachelor respectively on Thomas Seynt Just and Henry Habyngton. Probably these degrees were granted on the strength of pedantic lore formally required. In the following century a musical composition also was exacted from candidates for graduation. It may seem an anomaly that art-excellence should be tested by academical regulation, since by some supposed to soar above rule; but, rise as it may, to be art it must be founded on principle, and, if in its working of to-day it overstep its limits of yesterday, it is for ever unfolding new exemplifications of those natural laws whereon it is based, and the greatest artist of any time is he who can most deeply probe, and is thus best able to apply, the phenomena; upon these grounds, then, it is not beyond the province of the schoolman to test and to declare the qualifications of an artist.

Academical degrees.

The knightly calling, in the age of chivalry, not only referred to heroic acts and deeds of arms, but regarded skill in verse and melody, in singing and accompaniment. Princes and nobles of highest rank practised these arts, and were then styled troubadours, who were sometimes attended and assisted by jongleurs to play to their singing. See TROUBADOURS. Their music seems to have been rhythmical, as was necessary to fit the verses, and the perfect, or ternary, or triple time is said to have prevailed in it more commonly than that which we should now write as two or four in a bar. A similar race of knightly songsters in Germany were the minnesänger (see vol. x. p. 525). They set great value on the invention of new metres, and he who produced one with a melody to suit it was called a *meister* (master), while he who cast his verses in a previously accepted metre or adapted them to a known melody was styled *tondieb* (tone thief). For the most part, their pieces comprised a fore-song, a far longer section in several stanzas, to each of which the same melody was repeated, and an after-song, all three divisions having their own separate melody. Their music is said to have been in the church style of the period, but was distinctly their own composition. The exercise of the gentle arts by the nobility declined with the decline of chivalry, and as it fell into disuse among them it was adopted by the burgher class in the guilds of meistersänger (see vol. x. p. 526). One of the most meritorious and by far the most prolific of the whole craft—his compositions being numbered by thousands—was Hans Sachs of Nuremberg (1494-1576). He was by trade a shoemaker, and all the members of the guild followed some such calling, and devoted themselves to the study and practice of song as recreation from their daily labour. They cultivated the arts of both composition and performance of song in its twofold aspect of verse and tune, for which,

[1] As belonging to this branch of the subject, the principal schools for musical education that have been instituted of late, and are now in existence, may here be named:—the Paris Conservatoire, 1795, and its five provincial branch schools; the Conservatoire of Brussels; the Royal Conservatorio of Naples, an offspring of earlier institutions; the Royal Academy of Music, London, 1822; the Conservatorium of Leipsic, instituted in 1843, mainly through the instrumentality of Mendelssohn; the Conservatorium of Vienna, and like institutions in Dresden, Cologne, Stuttgart, Munich, and Frankfort, and also in Milan and Bologna; and the Hochschule für Musik, a branch of the Academy of Arts, Berlin.

according to tradition, they enacted most rigid and perhaps pedantic laws. None of their work has come down to us, but the name they have left affords an instance of the aspirations of the common people to that intellectual condition which is not the exclusive prerogative of the church, nor the privilege of the wealthy. Guilds of meistersänger were also established in other towns of North Germany. The title and its application generally declined until the 17th century, but lingered feebly in a few places until 1836, when the latest-lived guild was dissolved at Ulm.[1]

Madrigals and part-songs.

The dawn of the 16th century is marked by the appropriation of musical scholarship to secular writing. It was about that time that the *madrigal* came into vogue. The etymology of the word is obscure, but the class of music to which it is applied is clearly distinguished. It is stamped with the imitative character of the canon, but is free from the rigid continuance of one melody by the successively entering voices; and it has as much resemblance yet unlikeness to the fugue in having the flight of a musical phrase from one to another of the vocal parts, but not being steadfast to one subject throughout its design,—nay, imitation sometimes ceases in the madrigal when particular words need special emphasis. The *villanella, villancico, chanson*, or the *part-song* of the period is distinguished from madrigal by the definite rhythm, a quality excluded from this latter by the response in one part to the uncompleted phrase of another; and the lighter species of composition was so arranged as to suit a single voice with a lute accompaniment when a voice to each part was not available for the performance. Still more marked in rhythm and more slight in structure was the *ballet*, so named because it was sung as an accompaniment to dancing (*ballata*, from *ballare*), or the *fal-la*, so named because often set to these two syllables. All these classes of music were as often played as sung, and in English copies are generally described as "apt for voices or viols." The Flemish masters have left as many and as admirable specimens of secular work as of church music; Italian musicians, who rose from the teaching of the Flemings, successfully emulated the twofold example; but in England secular composition seems to have been the indigenous development of national intuition, and at its outset at least to have had a style of its own. This is exemplified in the pieces comprised in the *Fayrefax MS.*, which are mostly of a pastoral and always of a tuneful character; of these, Dr. Robert Fayrefax the collector, Sir Thomas Phelyppes (a priest), Newark, Theryngham, Turges, Tudor, Browne, Gilbert Bannister, Richard Davy, Cornyshe, and others were the composers.

Roman school.

The renowned Roman school, to which we must now pass, owed its existence to the precept as much as to the example of foreigners, chiefly from Flanders. Claude Goudimel (*c.* 1510-1572), known as a Fleming, though his birth be assigned to Avignon, was the first to open a seminary for musical tuition in Rome, and the most famous musicians of the century were its pupils—Palestrina (*ob.* 1594), Orlando di Lasso (*ob.* 1594), the brothers Animuccia, the brothers Nanini, and many more. Lasso, Lassus, or Latres of Mons is signalized among these for the great number and great beauty of his works, and for the wide area over which he spread his labours. In his own land, in Rome, in France, in England, and chiefly in Bavaria, he was active as a choir-master and as a composer, and did as much to advance art by making his music express the words to which it was set as by teaching the executants to realize this expression in performance. He is praised for breaking from the long previous practice of writing prolix florid passages to single syllables, a weakness manifest in the music of his countryman Desprès and of intervening writers.

Spanish writers.

Several musical treatises by Spanish writers of this period are extant, which are not regarded highly for the novelty of their views, nor for more than usual perspicacity in the statement of them. It might have been supposed that Spain would have been as favourable to the production of musical talent as Italy has always been. That the contrary is the fact is, however, patent; but the explanation lies with the ethnologist rather than with the musician.

Purification of church music.

Though the church from time to time appropriated the secular art-forms from their rise to their maturity, its chief authorities were always jealous of these advances, and issued edicts against them. So in 1322 Pope John XXII. denounced the encroachments of counterpoint, alleging that the voluptuous harmony of 3ds and 6ths was fit but for profane uses. So too the twelfth or Ionian mode—the modern scale of C major, the only one of the church modes, save under special conditions the fifth or Lydian mode, that accords with the tonality of present use—was stigmatized as "lascivious" and proscribed from the sanctuary. More accordant with present views of propriety was the many-sided objection to the employment of tunes of the people in place of the church's plain-song as bases on which to erect counterpoint, and the construction of this counterpoint in the most ornate of the several florid species. Enlarging on the primitive practice of adapting Latin words to popular tunes, the best approved masters, in the two centuries preceding the epoch now under notice, took tunes of this class, to which it is stated the original words were commonly sung by congregations at least, and even by some members of the authorized choir, while other of the singers had such extensive passages to execute that to make the sacred syllables distinct was impracticable. The whole custom of composition and performance was rigorously condemned by the council of Trent, in consequence of which Palestrina was commissioned in 1563 to write music for the mass that should be truthful to the spirit of devout declamation and aim at the utmost approach to musical beauty. To this end he made three experiments; the first two were declared successful, and the third was accepted as the fulfilment of all that could be desired for religion and for art; it was named, after the preceding pope, "Missa Papæ Marcelli." This great work was set forth as the standard to which all ecclesiastical composition was required to conform; and so it did conform until a new musical idiom arose, until the popular ear thirsted for new forms of expression, and until musicians sought and found favour in meeting the general demand. In the three hundred years between that time and this, pontiffs and conclaves have again and again enacted statutes to conserve the purity of ecclesiastical art, but art as often has run out of control and proved that every succeeding era adds to its capabilities.

Inflected notes in church music.

Despite the unbroken continuance of their use in the Roman service, great ignorance now prevails as to the church modes and their permitted modification. Ears trained by modern experience recoil from the uncouth effect of the melodic progressions incidental to some of these artificial scales, while antiquaries protest the infallibility of extant copies of music constructed in those modes, and insist on the authority of such manuscripts to secure purity of performance. A *Treatise on Counterpoint* by Stefano Vanneo of Recanati (1531), however, expressly states that the notes in the modes were subject to inflexion, that accomplished singers necessarily knew what

[1] Late in the 13th century a society somewhat similar in its object was established in London, consisting of the wealthier merchants. It was called the Puy (the name also given to the poetical festivals in honour of the Virgin in some Norman towns; see Littré, *s.v.*). Admission to its ranks was possible only through manifestation of musical or poetic merit. Severe judgment decided on the claims of contesting candidates for honours, which were great and public when desert was found.

notes should be raised or lowered by sharps or flats, and that these signs were never written but for the direction of boys and other executants who had not attained to mastery of their art. The treachery of tradition is exemplified in the loss of the rules for this once generally understood practice of *notal* inflexion; but the inference is strong that, could these rules be recovered, many of the melodies now called Gregorian might resume a musical character of which they are robbed by strict adherence to their written notes.

English school.

In England during the 16th century choral music kept pace with the age. This is evidenced in the works of Tallis and Byrde (Bird, or Byrd), who wrote for the Roman ritual, and continued their labours for the Anglican service as modified by the Reformation, which exercised the genius of many another, of whom Orlando Gibbons was the crowning glory, for the few of his works that are accessible in comparison with what he is believed to have produced are classed among the masterpieces of their style and their period. The same musicians, or most of them, are as notable for their secular as for their sacred writings.

Oratorio.

It was in the middle of the 16th century that the class of composition now ranked as the highest was originated. The *oratorio* dates its existence and its name from the meetings held by San Filippo Neri in the oratory of his church in Rome, at first in 1556, for religious exercise and pious edification. He was the confessor and friend of Giovanni Animuccia, whom he engaged to write music to be interspersed throughout his discourses. Originally this consisted of *laudi* or short hymns, the extent of which was afterwards enlarged; by and by the spoken matter was replaced by singing, and ultimately the class of work took the form in which it is cast by present composers. Such is the source of the didactic oratorio; the dramatic oratorio is an off-shoot of the same, but is distinguished by its representation of personal characters and their involvement in a course of action. The first instance of this kind of writing was the production of Emilio del Cavalieri, *La Rappresentazione dell' Anima e del Corpo*, which, like its didactic precursor, was given in the oratory of a church in Rome (1600)[1]

Dominant seventh.

To the beginning of the 16th century is due a more significant matter than the secularization of studied music, than the reform of the music of the church, and even than the labours of those musicians of whose great names only the most notable have been cited. The matter in question refers not to art-forms nor to artists, but to the fact that music has its foundation in the natural laws of acoustics, and thus it lays open the principle for which Pagan philosophers and Christians had been vainly groping through centuries, while a veil of mathematical calculation hung between them and the truth. Jean Monton of Holling in Lorraine (1475-1522) is the earliest musician in whose works has been found an example of the phenomenal chord of the dominant 7th approached with the full freedom of present-day practice. The discovery is usually ascribed to Claudio Monteverde, of whom and of his great art services much will be said when treating of the ensuing century. Like others of the wonders of nature, the chord and its application seem not to have come suddenly into knowledge, much less into acceptance, but to have been experimented upon with less or more of hardihood by one musician after another, until good effect had silenced dispute and authorized the adoption of this beautiful harmony into the language of music. The discovery of the grounds of its justification is to be traced to a still later time. The speciality of the chord consists in its comprising between its 3d and 7th the interval of the diminished 5th, the two notes of our diatonic scale which are omitted by many primitive nations—the 4th and 7th from the keynote—and which perplexed the considerations of theorists and practitioners, as has in the foregoing been repeatedly shown. Speculation as to the new delight the first hearing of this combination must have occasioned is precarious; the opposition with which it was encountered by the orthodox is certain.

Hymns and chorals.

Yet another prominent feature in musical history dates from the beginning of the 16th century, the practice of hymnody. Luther is said to have been the first to write metrical verses on sacred subjects in the language of the people, and his verses were adapted sometimes to ancient church melodies, sometimes to tunes of secular songs, and sometimes had music composed for them by himself and others. Many rhyming Latin hymns are of earlier date whose tunes are identified with them, some of which tunes, with the subject of their Latin text, are among the Reformer's appropriations; but it was he who put the words of praise and prayer into the popular mouth, associated with rhythmical music which aided to imprint the words upon the memory and to enforce their enunciation. In conjunction with his friend Walther, Luther issued a collection of poems for choral singing in 1524, which was followed by many others in North Germany. The English versions of the Psalms by Sternhold and Hopkins and their predecessors, and the French version by Marot and Beza were written with the same purpose of fitting sacred minstrelsy to the voice of the multitude. Goudimel in 1566 and Le Jeune in 1607 printed harmonizations of tunes that had then become standard for the Psalms, and in England several such publications appeared, culminating in Ravenscroft's famous collection (1621); in all of these the arrangements of the tunes were by various masters. The English practice of hymn-singing was much strengthened on the return of the exiled Reformers from Frankfort and Geneva, when it became so general that, according to Bishop Jewell, thousands of the populace who assembled at Paul's Cross to hear the preaching would join in the singing of psalms before and after the sermon.

Elaboration of choral tunes.

The placing of the choral song of the church within the lips of the people had great religious and moral influence; it has had also its great effect upon art, shown in the productions of the North German musicians ever since the first days of the Reformation, which abound in exercises of scholarship and imagination wrought upon the tunes of established acceptance. Some of these are accompaniments to the tunes with interludes between the several strains, and some are compositions for the organ or for orchestral instruments that consist of such elaboration of the themes as is displayed in accompaniments to voices, but of far more complicated and extended character. A special art-form that was developed to a very high degree, but has passed into comparative disuse, was the structure of all varieties of counterpoint extemporaneously upon the known hymn-tunes (chorals), and several masters acquired great fame by success in its practice, of whom Reinken (1623-1722), Pachelbel (1653-1706), Georg Boehm, and the great Bach are specially memorable. The hymnody of North Germany has for artistic treatment a strong advantage which is unpossessed by that of England, in that for the most part the same verses are associated with the same tunes, so that, whenever the text or the music is heard, either prompts recollection of the other, whereas in England tunes were always and are now often composed to metres and not to poems; any tune in a given metre is available for every poem in the same, and hence there are various tunes to one poem, and various poems to one tune.[2] In England a tune is named generally after

[1] The correspondence of this account with that of the rise of Greek tragedy is obvious.

[2] The old tune for the 100th Psalm and Croft's tune for the 104th are almost the only exceptions, unless "God save the King" may be

some place—as "York," "Windsor," "Dundee,"—or by some other unsignifying word; in North Germany a tune is mostly named by the initial words of the verses to which it is allied, and consequently, whenever it is heard, whether with words or without, it necessarily suggests to the hearer the whole subject of that hymn of which it is the musical moiety undivorceable from the literary half. Manifold as they are, knowledge of the choral tunes is included in the earliest schooling of every Lutheran and every Calvinist in Germany, which thus enables all to take part in performance of the tunes, and hence expressly the definition of "choral." Compositions grounded on the standard tune are then not merely school exercises but works of art which link the sympathies of the writer and the listener, and aim at expressing the feeling prompted by the hymn under treatment.

Recitative and lyrical drama.

On the verge of the 17th century a novelty in music was originated that was as pregnant of consequence as anything that has yet been noticed; this was *recitative* with its special characteristics. Vincenzo Galilei was one of a band of Florentine nobles and gentry who devised the appropriation of music to free declamation, and they engaged authors and productive and executive musicians to put the conception into practice. Galilei had already come prominently into public notice in a controversy with Giuseppe Zarlino, the most esteemed of all the writers on music in his age, who was the author of a treatise that expounded and justified the Ptolemaic division of the scale with the major and minor tones, and the former below the latter; this was answered by Galilei in support of the Pythagorean doctrine of equal tones, which is confuted by the phenomenon of harmonics, and Zarlino in turn replied to him. During two and a half centuries the art of music had been untouched by the New Learning, which had had the effect of regenerating all the other arts, and had wrought the intellectual change now known as the Renaissance. The members of the Florentine association thought it possible to apply ancient principles in modern practice, and so to reproduce the effect to which the newly-revealed writings of Greece testified, but of which these gave no such technical description as could be the groundwork of any reorganization. Obviously, the poetic power of Greek music must have lain in the force it gave to declamation; in exalting speech into song it must have given to words a clearer yet more varied significance than they could else have had, and to the passions words embody it must have given an otherwise impossible medium of expression. There existed two classes of music at the time under notice. The music of the people consisted of concise rhythmical

that none could be distinguished,—a fact that must be self-apparent if we think of the sound of twelve, or twenty-four, or so many as forty simultaneous currents of song. In this music there could neither be expression nor even articulation of the words, and hence, our Florentines assumed, the purpose of music was perverted and its inherent poetical essence was abused. Such combination of diverse melodies is now styled *polyphony*, a term that might better be applied to simple counterpoint in which the many sounds are onefold in accent than to the florid counterpoint it is employed to define, wherein the many parts have various movement. With the idea before them of the ancient rhapsodists the association proposed the setting of music to verses with the main, nay, only object of expressing the words. This music was not to be rhythmical, but was to consist of longer or shorter phrases in accordance with the literary sense; its intervals were not to be chosen with regard to their melodic interest, but in imitation or idealization rather than exaggeration of the rising and falling of the voice in ordinary speech, the speed being hurried or relaxed by the exigency of the passing sentiment; and the accompaniment of the singer was to be on some unobtrusive instrument or, later, some combination of instruments, that should, as did the lyre of old, verify the intonation and, in the new era (what had not been in the classic), enhance the vocal expression by some pungent harmony. Applied solely to recitation, the new invention was called *recitativo* (recitative), *musica parlante*, or *stilo rappresentativo*. The first instance of its composition is said to have been a *cantata*—that is, a piece for a single voice with instrumental accompaniment—*Il Conte Ugolino*, composed by Galilei, but of this no copy is known to exist. Doubt prevails as to whether *Il Combattimento d'Apolline col Serpente* by Giulio Caccini or *Il Satiro* by Emilio del Cavalieri was the earlier production; they were both given to the world in 1590, were both in dramatic form, and both exemplified the new, if not the revived, classic style of music. Caccini was fitted to make the experiment by practice and excellence as a vocalist more than by contrapuntal erudition, and he was soon associated with Jacopo Peri, a musician of his own class, in the composition of *Dafne*, a more extensive work than the foregoing, indeed a complete lyrical drama, which was privately performed in the palace of one of the Florentine instigators of the experiment in 1597, or, according to some, in 1594. These two again worked together on the opera of *Euridice*, which was publicly represented in Florence at the nuptials of Henry IV. of France with Maria dei Medici in 1600, its production having been preceded by that of Cavalieri's posthumous oratorio in Rome, *La Rappresentazione dell' Anima e del Corpo*, before noticed. That the first public performance of a dramatic oratorio and of a secular opera, both exemplifying the recently-devised declamatory power of music, should have occurred in the same year is a remarkable coincidence. That the first experiments in the novel art of lyrical declamation were confided to practised executants who brought their experience as vocalists to bear upon composition for a hitherto untried phase of vocal effect was excellent for the purpose of proving the proposition. The success of the experiment was, however, to be established when a composer already renowned as such, one who had drawn exceptional attention by his then new views of harmony, gave the force of his genius and the weight of his name to the novel class of writing. Such was Monteverde (1568-1643), who in 1607 brought out at the court of Mantua his opera of *Arianna*, followed in 1608 by his *Orfeo*. In these works, and in those of the same nature that he subsequently produced at Venice, is anticipated the principle (and, so far as the resources of the time allowed, the practice also) which was revived by

Gluck some hundred and fifty years later, and of which the votaries of Richard Wagner in the present day assume their hero to have been the originator,—the principle, namely, that the exigencies of the action and the requirements of the text should rule the musical design in a lyrical drama, and that the instrumental portions of the composition should, quite as much as those assigned to voices, illustrate the progress of the scene and the significance of the words. The last speciality is exemplified in the harmonies and figures of accompaniment, and in the appropriation of particular instruments to the music of particular persons, so as to characterize every member of the action with special individuality. Such must be the true faith of the operatic composer: it has again and again been opposed by the superstition that feats of vocal agility and other snares for popular applause were lawful elements of dramatic effect; but it has ever inspired the thoughts of the greatest artists and revealed itself in their work, and no one writer more than another can claim to have devised or to have first acted upon this natural creed.

Fundamental discords opposed to contrapuntal style.

Monteverde had been attacked by Giovanni Battista Artusi for his use of what are now known as fundamental harmonies, which the composer might have learned from the music of Mouton (already named), but which he more probably rediscovered for himself; he had defended the practice, and his theoretical assailant had retorted. Polemics ran high as to the relative rights of contrapuntal legislation which had been developed through the course of ages, and the freedom of thought which had as yet neither rule nor tradition; for every separate use of an unprepared discord was tentative as to effect and speculative as to reception by its hearers. It will presently be shown that the discovery (no lighter term will suffice) of Mouton and Monteverde has its base in the laws of nature; here it is enough to say that it was a turning-point in the history of music, the throwing open the resources of the modern as opposed to the limitations of what may justly be called the archaic. The distinction of these two styles was not clearly defined till long afterwards; but a writer may here be named, Angelo Berardi, whose work (1687) more fully than any other sets forth the contrapuntal code and enunciates the requirements in fugal writing, such as the affinity of subject to answer, and whatever else marks the style and the class of composition.

Italian opera.

The opera now became a fixed institution in Italy, its performance was no longer restricted to the palaces of princes and nobles, and it became the best-esteemed entertainment in public theatres. The dramatic oratorio was transferred from the church to the secular stage, becoming in every respect a sacred opera, and only specimens of this class were suffered to be represented during the season of Lent.

A. Scarlatti.

Conspicuous, as much for the merit as the multitude of his productions, was Alessandro Scarlatti (1659-1725), who gave to the world 115 secular operas, many oratorios, and, besides these, which might well have been a long life's labour, a far greater quantity of ecclesiastical music, some of which is characterized as most dense and massive. He is accredited with three novelties in his dramatic writing: the repetition, *Da Capo*, of the entire first part of an aria after the second part, of which, however, some specimens by earlier writers are said to exist; the accompanied recitative, wherein orchestral interludes illustrate the declamation and figurative accompaniment enforces it, as distinguished from speaking recitative, wherein the accompaniment does little more than indicate the harmony whereon the vocal phrases are constructed; and the *sinfonia* or *overture* which is often associated with his name, as distinguished in plan from that which was first written by Lully, his being sometimes styled the French and Scarlatti's the Italian form of instrumental preface to an extensive work.[1] Alessandro Scarlatti is little less famous as a teacher than as an artist; he was at the head of all the three conservatories then flourishing in Naples, and the long list of his pupils includes his son Domenico and most of the other chief Italian notabilities of the next generation. Conspicuous among his contemporaries were Cavalli and Cesti.

French opera.

Opera was first introduced in France by Cardinal Mazarin, who imported a company of Italian performers for an occasion. The first French opera, *Akebar, Roi de Mogul* (1646), was composed by the abbé Mailly for court performance. So was *La Pastorale* (1659), by Cambert, who built his work on the Florentine model, and, encouraged by success, wrote several others, on the strength of which he, with his librettist Perrin, instituted the Académie Royale de Musique, and obtained a patent for the same in 1669, exclusively permitting the public performance of opera. Jean Battiste Lully[2] (1633-1687) procured the transfer of this patent in 1672, and by it gained opportunity not only for the exercise of his own genius but for the foundation of the French national lyrical drama, which to this day is wrought upon his model.

Lully.

The ballet had been a favourite subject of court diversion since Beaujoyeaulx produced in 1581 *Le Ballet Comique de la Royne*, a medley of dancing, choral singing, and musical dialogue. Lully, in his course to the summit of royal esteem, had composed several pieces of this order, which were performed chiefly by the courtiers, and in which the king himself often sustained a part; and, experienced in the taste of the palace, and indeed of the people, our musician incorporated the ballet as an essential in the opera, and so in France it still remains. It was not singly in the structural intermixture of dancing with singing that Lully's operas were, and those of his French successors are, unlike the works of the same order in other countries, he gave such care to and exerted so much skill in the recitative that he made it as interesting as the rhythmical matter, nay, varied it often with metrical vocal phrases and accompanied it constantly with the full band, whereas, until Rossini's *Otello* in 1818, speaking recitative (recitativo parlante, recitativo secco) was always a main element in the operas of Italy.

German opera

In Germany the seed of opera fell upon stony ground. Heinrich Schütz wrote music to a translation of Peri's *Dafne*, which was performed for a court wedding at Torgau in 1627; but only importations of Italian works with Italian singers came before the public until nearly the end of the century.

English opera.

In England the lyrical drama found an early home. The masques performed at Whitehall and at the Inns of Court were of the nature of opera, and were largely infused with recitative. Eminent among others in their composition were Nicholas Laniere (c. 1588-1664), born of an Italian father who settled in England in 1571; Giovanni Coperario, who during his sojourn in Rome had thus translated his patronymic of John Cooper; Robert Johnson, who wrote the original music for *The Tempest*; Dr Cam-

[1] The Italian "sinfonia" mostly begins with an allegro, which is succeeded by a shorter adagio, and ends with a second quick movement that is sometimes the resumption of the first and is sometimes independent of it, and it is exemplified in the overtures to the *Seraglio* of Mozart, the *Euryanthe* of Weber, and several of Auber. The French "ouverture" (the original form of the word, which still remains in France) generally begins with a majestic movement, which is followed by an allegro, often of a fugal character, and concludes with a march or gavotte or some other description of dance, and it is exemplified in the overtures of Purcell and nearly all of those of Handel.

[2] This is the French form of his names Giovanni Battista Lulli, adopted after he was taken from Florence to Paris as a page.

pion, Ives, and William and Henry Lawes. The name of Henry Purcell (1658-1695) figures brightly in this class of composition; but, except his *Dido and Eneas*, written when he was eighteen, his so-called operas are more properly spoken dramas interspersed with music—music of highly dramatic character, but episodical rather than elemental in the design. This is due to an axiom of Dryden, the principal and indeed the model dramatist of the day, that music is not the natural medium of speech, and hence may only be assigned in dramatic representation to preternatural beings, such as spirits, enchanters, and witches,—maniacs also, through the abnormality of their condition, being admitted into the privileged category of those who may sing their conceits, their spells, their charms, and their ravings. The "frost scene" in *King Arthur*, the "incantation" in the *Indian Queen*, and the cantatas for Altisidora and Cardenio in *Don Quixote* are masterpieces of lyrical art that give warrant of the success that might have been achieved had Purcell's librettists given range in the province of humanity for his vivid imagination.

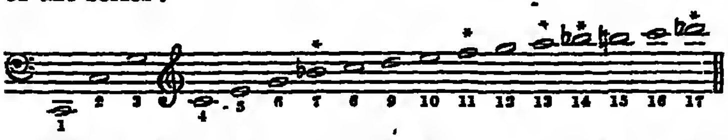
Puritan influence. Earlier in the history of English opera was the production of *The Siege of Rhodes*, an entirely musical composition, the joint work of Dr Charles Colman, Captain Henry Cook, Henry Lawes, and George Hudson, which was performed at Rutland House in Charterhouse Square in 1656, under the express licence of Cromwell to Sir William Davenant, and retained the stage until some years after the Restoration; the existence of its music is unknown, but a copy of its libretto in the British Museum amply details its construction. Separate mention is made of this remarkable historical incident as serving to refute the common supposition that Puritan influence impelled the decadence of music in England. In truth, this influence stirred the spirit of opposition in persons of a different tendency and was virtually the cause of a very powerful counteraction, and through this of many highly-significant things as to the perpetuation of our music of the past, if not of the continuance of our music in the future. It was during the Commonwealth that John Playford printed *Ayres and Dialogues*, a book that comprises with many pleasant pieces the first three that ever were defined by the word *glee*,—a term that later times have wontedly acknowledged and boasted as the designation of a class of music specially English. It was during the Commonwealth that the same publisher issued several editions of *The Dancing Master*, each being a variation of the foregoing; and this is the work to which we owe the preservation of all the beautiful English ballad-tunes of earlier date that are, many of them, not to be found in previous print or manuscript. It was in that very opera, *The Siege of Rhodes*, that Mrs Colman, daughter-in-law of one of the composers, sustained the character of Ianthe, she being the first female who ever took part in a public musical or dramatic performance in England.

Cantata. Notice must not be omitted of the application of recitative to other than theatrical purpose. The cantata of Galilei has been cited; it was followed by many a piece under the same designation, dramatic monologues in which the mainly prevailing declamation was relieved by occasional rhythmical strains, and in the composition of these Carissimi, Stradella, Ciari, Purcell, and Blow have left admirable specimens. Later, the term acquired a widely-changed meaning, it having been applied in Germany to compositions comprising matter for solo voices and for chorus, expressly for church use, and in England to works equally extensive on sometimes sacred, sometimes secular subjects. Cantatas are sometimes didactic, sometimes narrative, and sometimes dramatic, though never designed for theatrical use.

English church music. The music of the English Church might demand a separate history, because of its importance by the side of the art of other lands, because of the longer permanence of its examples than of works in other branches, and because of its unbroken succession of contributors, covering a period of beyond three centuries, whose style has varied with the age in which they wrought, but who in this department have ever aimed to express themselves at their highest. Here, however, only the names of the most noted writers, with an approximation to chronological order, can be given —Tallis, Byrde, Farrant, Orlando Gibbons, Dr Child, Dr Benjamin Rogers, Dean Aldrich (as distinguished in logic and in architecture as in music), Dr Blow, Michael Wise, Pelham Humphrey, Henry Purcell, Dr Croft, Dr Greene, Dr Boyce, Dr Nares, Dr Cooke, Battishill, after whom the art sank in character till it received new life from the infusion of the modern element by Attwood, coeval with whom was Samuel Wesley, and lastly are to be noted Sir John Goss, Dr S. S. Wesley, Dr Dykes (popular for his hymn-tunes), and Henry Smart, who bring the list down to recent personal remembrance. Well esteemed among living representatives of this department of music are Barnby, J. B. Calkin, Sir G. J. Elvey, Gadsby, Dr Garrett, Dr Gladstone, Dr H. Hiles, Dr Hopkins, Dr E. G. Monk, Dr W. H. Monk, Sir F. A. G. Ouseley, Dr Stainer, Dr Steggall, Sir Arthur Sullivan, and E. H. Turpin, to which names many might be added. It must be owned, however, that the vast increase of facilities for publication within recent years have multiplied church music almost immeasurably, and exercised the pens more than the wits of writers who prove themselves to be amateurs less by love of music than by love of composing, and still more by love of notoriety, which is gratified in the circulation among their own connexions of works that gain no acceptance by the world at large. The style, in strictly technical sense, of music for the church is and always has been, in England and elsewhere, identical with that which characterizes contemporaneous music on lay subjects. Some English musicians have of late aimed at, or perhaps only spoken of, a distinction of styles for the church and for the chamber, and this under a supposition that to be archaic was to be sacred, a supposition seemingly founded on the present use of, and high respect for, more ecclesiastical music of early date than of secular music of like age. The supposition overlooks the facts, however, that the church appropriated the tunes of the people eight hundred years ago, while the people framed some of their tunes on the peculiar church modes, that harmony was practised by the people before it was employed by the church, that the style of madrigals appears coincidently in sacred writing, that recitative was first applied to the opera and to the oratorio in the same year, that Monteverde's innovations in musical combination were at once adopted by church composers, that Purcell, Handel, and Bach wrote in onefold style for both situations, that the glee-writing of the latter half of the 18th century is undistinguishable from the services and anthems of the period, that Attwood had no different phraseology for the cathedral and the theatre, and that even now, though disguised to the glance by the antiquated notation of minims instead of crotchets, the thoughts expressed and the idiom which is their medium belong not more or less to the one than to the other purpose. Though contention be strong for the contrary, this is true art, presenting the feelings of the time in the time's own language and not making the sanctuary walls a boundary between art and artifice.

Harmonics. Attention must now be directed to the natural as opposed to the artificial basis of music. Marin Mersenne had great love and much practical knowledge of music; he directed his profound learning and rare mathematical attainments to the investigation of the phenomena of sound; and

his treatise *Harmonie Universelle* (1636) first enunciated the fact that a string yields other notes than that to which its entire length is tuned. The discovery was extended by William Noble and Thomas Pigot, respectively of Merton and Wadham Colleges, Oxford, to the perception of the mode in which a string vibrates in sections, each section sounding a different note. The ancient musicians tested by calculation the few phenomena of sound then discovered rather than by observation of the principles these exemplify. The measurement of major and minor tones was, after the distinction of perfect intervals, the subject dearest to their consideration, and it seems the furthest limit to which their knowledge attained. All the laws for melody, all the rules for counterpoint, were founded on this mathematical method. The step or the leap of stated intervals was prescribed; combinations of sounds were reckoned by intervals from a named note, as 5th, or 6th, or 3d, not as constituting complete chords traceable to a common source, and intervals which are discordant were permissible only if softened in effect by the previous sounding of their discordant note; the canons for the progression of a single part and for the union of several parts were arbitrarily devised, peremptorily fixed, and rigidly enforced. Mouton and Monteverde found the good effect of musical combinations for which there was no account in the theory of their time, and employed them in their works; the innovation was stigmatized by musical grammarians, but it gave delight to the public and was adopted by subsequent composers. No explanation was, however, given of the natural source of fundamental harmonies, as chords of this class are now defined, and their employment was still exceptional, still an act of daring. In 1673 the two Oxonians above named, simultaneously, but independently, noticed the beautiful fact that a stretched string yields a different sound at every one of its nodal divisions, and the same is true of a column of air passing through a tube. The sounds so generated received from Sauveur[1] the name of *harmonics*, by which they were known for nearly two centuries, but they have of late been renamed partial tones or over-tones.[2] Here is a table of seventeen of the series:—



The figures under the notes show the number of each harmonic, counting from the generator or prime as the 1st. The notes marked * differ in intonation from the corresponding notes in our tempered scale, the 7th and 14th, and also the 13th, and likewise the 17th being slightly flatter, and the 11th being slightly sharper than our conventional notes; but the matter of temperament must rest for later consideration. The 8th above any note is double the number of that note; thus every higher C is double the number of the C below it, namely, 1, 2, 4, 8, 16; and so with every higher G, namely, 3, 6, 12; again with the higher E, namely, 5, 10; and with the higher ♭B, namely, 7, 14. The number of each harmonic is the same as that of its relative number of vibrations in any given time as compared with those of the variously-numbered harmonics, namely, the 8th above has two vibrations to each one of the note from which the interval is reckoned, the 5th has three vibrations to two, and so forth throughout the series. From ♭B to E, the 7th and 10th, is the interval of the augmented 4th, which was shunned in classic times, ignored by the Chinese, the Mexicans, and the Scots, ruled against by contrapuntists, and avoided in melody and harmony until employed by the Fleming and the Italian with such good effect that the world accepted it under the conditions of accompaniment with which those men employed it, and felt that a new element of beauty had been incorporated in the resources of the artist. The occurrence, in the harmonic series, of the two notes that are separated by this interval accounts for the discord they produce when sounded together, not needing the artifice of preparation which is required to mitigate the harshness of other discords; they are brought into being when the generator is sounded, and their assignment to voices or instruments in performance is but to make more articulate, or, so to speak, to confirm what nature prepares—in fact, what is induced by the generator. As light comprises all the colours and every gradation between each colour and the next, but yet seems spotless, so every musical sound comprises all other sounds, but yet seems to be one single note; the blue, or the red, or the yellow, or any other ray is separated from its prismatic brotherhood and seems then a complete and independent object to the vision, and so any sound is separated from the harmonic column and then seems all in all to the sense of hearing. Let the reader observe in the musical example that the intervals become closer and closer as they rise, and that when the 8th or double of a note occurs, if there be any break in the numerical succession between such 8th and the note that would, by example of the lower octave, stand next below it, then some new harmonic appears whose number adjusts the broken order; between the lowest C and the next is no break; between this C and the one above it, 2 and 4, what would else be a blank is filled by G, the third harmonic; between 4 (C) and 6 (G) what would be a blank is filled by E, the fifth harmonic, and so on throughout the series. No division of an interval is ever equal, the lower portion being always the larger; the interval between 2 and 4 is divided into a 5th and a 4th, that between 4 and 6 is divided into a major 3d and a minor, that between 6 and 8 by an interval less than a minor 3d and a 2d, and that between 8 and 10 by a major tone and a minor tone. It may be well to pause at this point, as it is the natural justification of what Ptolemy calculated, but Pythagoras failed to perceive. Thus much having been noticed, readers may be left to trace the same principle of larger and smaller division throughout the series. Beyond the 17th harmonic (the note known as the minor 9th when forming part of a chord) the series continues on the same principle of ever lessening distance, ever finer gradation, until the intervals become so small as to be almost impossible of articulation and of perception. What has here been adduced of the natural preparation of the discord of the harmonic 7th applies as truly to the discords of the major 9th, the 11th, the major 13th, the minor 9th, and the minor 13th, which last is too high in the harmonic series for convenient exemplification by gradual ascent in this place, and these notes are now all used in combination by composers.

Art the precursor of science.

Scientific discovery has seldom been made singly. When time has been ripe for the revelation of a phenomenon, several observers have coincidently witnessed its existence, and simultaneously or nearly so displayed if not explained it to the world. In the instance under consideration, art foreran science, and its votaries continued the employment of harmonies which as yet could alone be justified by their beautiful effect, and even musical theorists did not for ages to come perceive the important, the all-powerful bearing of the principle of harmonics upon the subject they treated. What Mouton first ventured to write must be styled the starting-point of the modern in music, and one cannot too much marvel at the strong insight into the beautiful which those after-minds possessed,—that, with no theory to guide, without star or compass, they

[1] See Poggendorff, *Geschichte d. Physik*, p. 808.
[2] See Helmholtz, *Die Lehre von den Tonempfindungen.*

made wider and wider application of the principle he had exemplified, and displayed in their works its utmost power of expansion. Three of the world's greatest musicians may be cited to show the force owned by genius of piercing to the utmost depth of a natural law, while having but their own delicate sense of propriety to restrain them within its bounds. Henry Purcell and his two colossal successors, George Frederic Handel (1685-1759) and Johann Sebastian Bach (1685-1750), wrote every combination of musical notes that down to our own latest times has ever been employed with good effect; and the more the works of these masters are studied the more are they found to foreshadow the supposed novelties in harmony employed by subsequent artists. This refers but to the technical materials of which their music is wrought; it is impossible in the present article to discuss fully the form and excellence of their works.

Purcell.

Purcell's voluminous and superb works for the church, his many compositions for the theatre, his countless convivial pieces, and his far less numerous instrumental writings are now but little known, and the ignorance of the age is its loss. They have a wealth of expression that cannot be too highly esteemed, and a fluency of melody that proves the perfect ease of their production. The idiom of the period in which they were written is perhaps a partial barrier to their present acceptance, and the different capabilities of instruments and of executants upon them of those days from the means at a modern musician's command make the music written in the earlier age difficult sometimes to the verge of possibility, and yet weak in effect upon ears accustomed to later uses.[1]

Handel.

Handel's music has never, since he wrote, been wholly unknown or unloved, at least in England. He was engaged to come hither as a dramatic composer because of his Continental renown; this was immensely increased by the large number of Italian operas he wrote for the London stage, but, excellent of their kind as are these, the change of structure in the modern lyrical drama unfits the wonted witnesses of the works of the last hundred years to enjoy the complete performance of those of earlier time, and hence we hear but detached excerpts from any of them. It is upon Handel's oratorios and his secular works cast in the same mould that general knowledge of his mighty power rests, and these are a monument that cannot perish. The *Messiah* and *Israel in Egypt* are didactic oratorios, with which may be classed *L'Allegro, il Penseroso, ed il Moderato*, and *Alexander's Feast*. The others were defined by himself each as an "oratorio or sacred drama," and *Acis and Galatea*, *Semele*, and *Hercules* are similarly constructed. *Esther* (his earliest English oratorio) and *Acis and Galatea* were composed for performance in the mansion of the duke of Chandos in 1720 and 1721, and were publicly produced with the author's sanction in 1732, but then, as was expressly notified, without dramatic action. Their success established the class of work and form of representation in English use, for, though Handel subsequently wrote Italian operas, he from time to time engaged a theatre for the performance of complete works in concert wise, and yearly composed some new piece for production in this manner. In 1741 he visited Dublin, taking the *Messiah*, which had been written with a view to the occasion, and this masterpiece was first heard on the 13th April 1742 in the Irish capital. The reverence with which the work is regarded in England all but equals that for its subject, and the countless repetitions of its performance have made it so familiar to all hearers that the unversed in musical knowledge, little less than the profoundest musicians, feel its sublimity and listen to it with such awe as no other work of art induces. No master has ever excelled Handel in verbal declamation (as at the descent on the last word of "sheds delicious *death*" in the air of Acis, at that on the last word of "so mean a triumph I *disdain*" in the air of Harapha, and the extraordinary use of an almost toneless low note of the tenor voice on the last word of "He turned their waters into *blood*" in *Israel in Egypt*), in poetic expression (as in the choruses "He sent a thick darkness" in *Israel*, and "Wretched lovers" in *Acis and Galatea*), or in dramatic characterization (as in all the personages in *Jephtha*, who are each distinguished from the others far better in their musical than their verbal phraseology); but the quality in his music which compels the epithet sublime is the broad, simple grandeur of the choral writing, which, rich in the devices of counterpoint, never fails in clearness, never in the melodious flow of each of its parts, and is hence as pleasant to executants as it is perspicuous to auditors. He wrote under the sway of contrapuntal law, from which theorists had not yet defined the exceptions, but the force of his genius broke occasionally through its despotism, and so, in his works as in Purcell's, the principle of fundamental harmony and the application of the chromatic element are freely demonstrated.[2]

Bach.

Bach was one of a very large family of musicians, who for two centuries practised the art, in many instances with great success; the family glory culminated in him, and was scattered among his many sons, in whom it became extinct. Bach was a more assiduous student than either his predecessor or his contemporary who are here classed with him. It was later in life than they that he issued his earliest works, for his youthful renown was more as a player than as a producer. Having no theoretical instructor, he made searching study of all the music of earlier times and of his own.[3] Whatever Bach learned of the principles of counter-

[1] Here must be defined the chromatic genus in its modern application, which is signally exemplified in this master's music; it admits of notes foreign to the signature of the key, but which induce no modulation, or, in other words, change of tonality. Notes expressible only by accidentals are as essential to the chromatic scale of any prevailing key as are those elemental in the diatonic scale which are indicated by the key-signature. Chromatic chords were used by Purcell and his earliest followers, chromatic passing-notes (notes that form no portion of chords) came little into use until after the middle of the 18th century.

[2] A custom of the age is largely and, we now feel, sadly exemplified in Handel's art legacies, namely, the writing in many instances but an outline of the score which was to be filled up extemporaneously by a player on the organ or harpsichord with counterpoint that is necessary to the effect, and even essential to the idea. So long as the composer lived to make these improvisations, we know they added interest and we doubt not they added beauty to the music; but after-organists lack the ability or courage or both to supply the deficiency. Mendelssohn wrote for *Israel* such an organ part as he would have played in the performance of the oratorio, diffidently deliberating on what originally was trusted to the fortune of the moment, and the like has rarely been done by other musicians for other works. Mozart wrote for the *Messiah*, *Acis*, *Alexander's Feast*, and the *Ode for St Cecilia's Day* wind-instrument parts comprising such matter as might have been played on the organ had one been in the hall wherein these pieces were first performed in Vienna; but they modernize the character and often alter the idea, while they complete and perhaps adorn the music. That these parts exist, and that their merit induces their adoption when the works are performed, have been a licence for the production of "additional accompaniments" to many a masterpiece of Handel, when such genius as Mozart had has not inspired the writer. The former custom and the later licence are both to be deplored, particularly in our age, when with regard to other arts the aim prevails to purify the works of older time from additions by strange hands that have accumulated to disfigure them.

[3] Among the masters from whose example he deduced his own principles, some of the most famous are Girolamo Frescobaldi of Ferrara (*c.* 1587), his pupil Johann Caspar Kerl (1628-1693), Dietrich Buxtehude (1637-1707), Johann Jacob Froberger, another pupil of Frescobaldi (*ob.* 1667), Georg Muffat (*ob.* 1704), whose son was even more prolific and perhaps more noted than he, Johann Pachelbel, Georg Boehm, and most probably Johann Joseph Fux (1660-1741), whose work on counterpoint, *Gradus ad Parnassum*, was the text-book by which both Haydn and Mozart taught, and is still held in high respect.

point from profounder musicians, he owed his views of plan or design in the structure of a composition to his familiarity with the concertos of Antonio Vivaldi and Tomaso Albinoni, both Venetian violinists who visited Germany, and he gained this familiarity by arranging for the organ many of the concertos for several instruments, as also much that the same authors wrote for a single violin. His arrangement consisted in adding parts to the original, which he kept intact, and so retained the plan while enriching the harmony. To his latest days he was wont to retouch his own music of former years, doubtless with the purpose of improvement, and he thus showed himself to be still a student to the very end of his career. A class of oratorio of which Luther had planted the earliest germ, the recitation of the Divine Passion, had grown into extensive use in North Germany prior to the period of Bach, and to this belongs his largest if not most important work. This is his setting of the portion of St Matthew's Gospel which narrates the incidents, interspersed with reflective passages, some taken from the chorals of common use in the Lutheran and Calvinistic churches (the tunes proper to which have special harmonic treatment when here appropriated), and some set in the form of airs, duets, and choruses to verses written for the occasion. Bach set also St John's version of the Passion, and others. He wrote likewise for church use cantatas peculiar to every Sunday's requirement in the Lutheran service, and left five series of these, each for an entire year. He produced other sacred and many secular cantatas, a mass of such colossal proportions that it is unavailable for the purpose of celebration, other pieces for the Roman Church, very much for the organ alone that has never been equalled in its intrinsic qualities or as a vehicle for executive display, many concertos and suites for the orchestra of the day, and a vast number of pieces for the harpsichord or clavecin. Among these last must be signalized *Das wohltemperirte Clavier* (1722), and a sequel to the same, *XXIV. Preludien und Fugen durch allen Tonarten, sowohl mit der grossen als kleinen Terz* (1740).[1] These two distinct works are now commonly classed together as *Forty-eight Preludes and Fugues*. To describe their purpose reference must be made to the discrepancies between the tuning of intervals by 3ds, or by 8ths, or by 5ths. The B♯, which is reached by successive 3ds above C, has 250 vibrations in the same period that the C, which is reached by 8ths from the same starting note, has 256, and in the same period that the B♯ which is reached by 5ths from the original C, has 259 and a fraction. The same is true of every other musical sound as of C, namely, that tuning by 3ds, or 8ths, or 5ths, yields a different note from the other two. Hence it results that notes which are in tune in one key are out of tune in other keys, and consequently musical composition was of old limited to those very few keys that have several notes in common with the key of C.[2] The organ Handel presented to the chapel of the Foundling Hospital, London, had the raised or black keys divided, with each half to act on pipes different from the other half, and thus gave different notes for C♯ and for D♭, and the like; and other organs of the period were similarly constructed. Bach's notion was so to temper the intonation that, while the tuning of no key should be perfect, the discrepancies should be divided so nicely between all keys that no one would be offensive to the hearer, and to illustrate this he wrote in his 38th year a series of pieces in every one of the keys in its major and minor form, calling it "The clavier with equal temperament." This bears on a supposition, once

Temperament.

diffidently advanced and since confirmed by men who have soundly studied the subject, as much as by constant observation of him who first conceived it, although disputed by others; it is, that the ear receives tempered sounds as they should be, instead of as they are, perceiving a different effect from the note whose tonal surroundings prove it to be ♭G from that which is yielded by the same string on a pianoforte when it is required to represent ♯F. Such is the practical application in modern use of the term enharmonic with reference to keyed instruments when it means the giving different names to one note: on the voice, however, and on bowed instruments the smallest gradations of pitch are producible, and so all notes in all keys can be justly tuned, which, among others, is one reason for the exceptional delight given by music that is represented by either of these means. The enharmonic organ and harmonium of Mr Bosanquet are provided with a keyboard of a general nature in which the restriction to closed circles of 5ths is avoided. Systems reducible to series of 5ths of any character can therefore be placed on this keyboard. As the relative position of the keys determines the arrangement of the notes, the fingering is the same in all keys, and depends only on the intervals employed. The modern use of the word chromatic has already been stated, and it only remains to say of the other of the three Greek genera, diatonic, that the term now defines music consisting of notes according to the signature of the prevailing key.[3] To return to Bach, his orchestration is completer than Handel's, though yet needing the addition of an organ part that he did not write, but his scores are liable to misrepresentation in modern performance because several of the instruments are obsolete for which they were designed; Bach's orchestral treatment differs from that of later days in having often a special selection of instruments for a single movement in a work, which are engaged throughout that piece with small variety of interchange, and likewise in having mostly the separate counterpoint for every instrument employed instead of combining instruments of different tone in one melody. But seldom Bach wrote in one or other of the ecclesiastical modes, as did Handel more rarely, and he used more freely than his contemporary the extreme chromatic discords. He may indeed be regarded as a double mirror, reflecting the past in his contrapuntal writing and forecasting the future in his anticipation of modern harmonies.

Enharmonics.

Diatonic.

Notice of these two extraordinary men would be incomplete without an attempt to parallel if not compare them. Born within a month and within walking distance of each other, speaking the same tongue, professing the same religious tenets, devoting themselves to the same art and to the same productive and executive branches of that art with success that cannot be surpassed, they were as different in the character of their works as in their personal traits and their courses of life. The music of Handel for its simple, massive, perspicuous grandeur may be likened to a Grecian temple, and that of Bach to a Gothic edifice for its infinite involution of lines and intricacy of detail. The greater complexity of the one makes it the more difficult of comprehension and more slow in impression, while the sublime majesty of the other displays itself to a single glance and is printed at once on the mental vision. Handel wrote for effect and produces it with certitude upon thousands; Bach wrote as a pleasurable exercise for mastery, and gives kindred pleasure to those who study his work in the spirit that incited him to produce it.

Contemporary with the working of these two glorious Saxons were the labours of Jean Philippe Rameau (1683-

Rameau.

[1] Supposed by some to have been completed in 1744.

[2] It is supposed that early organs were tuned with true 3ds and flattened 5ths (the "mean tone" system of Zarlino and Salinas), and Mersenne enunciates, though obscurely, a rule for this division.

[3] Some theorists use the generic terms in limited sense:—diatonic, proceeding by 2ds; chromatic, proceeding by semitones; enharmonic, changing the name of a note.

1764), a native of Dijon, who made his mark on history. He wrote many operas and ballets which are held in less esteem than those of Lully, some cantatas and sacred pieces, and a large number of compositions for the organ and clavecin, but, notwithstanding the merit of these and their success, it is more as a theorist than as an artist that he is now regarded. He published several treatises, embracing principles of performance as well as rules of harmony and a system of composition, and the original views these enunciate have obtained high regard. He distinguishes what he styles the "basse continue" from what he names the "basse fondamentale" in tracing inverted chords to their roots, and differs in this from writers on counterpoint who treated only of intervals from each actual bass note. Thus he looked in the direction of later theories of fundamental harmony, but scarcely obtained sight of the object. He speaks of a chord of the 11th apart from the suspension of the 4th; but his examples show this to be the double suspension of the 9th and 4th, to be resolved on the root and minor 3d of a chord of the prepared 7th, which further has to be resolved on a chord whose root stands at a 4th above its own, and so this chord, having nothing exceptional in structure or treatment, needs no distinctive title.

Chord of the 11th.

Another point is indeed original, and has obtained somewhat wide acceptance; this is his theory of the chord he defines as the "great 6th," which is named the "added 6th" by his English followers. It consists of a common chord (usually of the subdominant) with a 6th added, and its resolution is on the chord whose root is at a 4th *below* that of the discord, the 5th in the former chord being retained as the root in the latter.

Chord of the added 6th.

 or 
Against this view it may be urged that all harmonic intervals are at uneven numbers from the generator, the even numbers standing for the octaves above any of these, as $\begin{smallmatrix}8 & 10 & 12\\ 1 & 3 & 5\end{smallmatrix}$, or else for their inversions, as $\begin{smallmatrix}6 & 4 & 2\\ 3 & 5 & 7\end{smallmatrix}$, and hence the 6th (D in the above example) is not an original but an inverted interval; further, whatever note may be added in a column of harmony does not affect the concordance or discordance of the notes below it, but is itself the discordant element in the chord, whereas the addition of the 6th to a common chord changes its concordant 5ths into a discord, and therefore the 6th must be otherwise traced. Other theorists have, more in the direction of truth, defined this chord as a first inversion, reckoning the 6th from the bass as the inverted root, but giving no account of its exceptional resolution. It was not till the following century that the theory for this chord was propounded with the seeming of truth, showing that the 7th below its given bass (G under the F in the above) is the real generator, and showing this to be an incomplete inversion of the chord of the 11th, of which Rameau invented but misapplied the name. The subject will be more fully discussed when the period is treated to which this last theory belongs.

Marcello. Benedetto Marcello (1686-1739) was a Venetian of wealthy parentage. He was pressed by his father into the pursuit of the law, and held lucrative appointments in his profession, but his love was for music, and in music he has some renown, partly for his compositions, the best known of which are the settings for one or more voices of fifty of the Psalms in an Italian version, and partly for his writings on music, especially a satirical pamphlet, *Il Teatro alla moda* (1720), as remarkable for the justice with which it censures the corruptions that cankered dramatic art as for its humour. This treatise quotes the principles of the Florentine assumed musical revival in 1600, and is regarded as the precursor of the practical reform effected by Gluck.

Rousseau. The renowned Jean Jacques Rousseau (1712-1778) is often accredited as a musical theorist because of his several publications on the subject, especially his *Dictionnaire de Musique*, which was finished in 1764, licensed in 1765, but not published till 1768. Its repute must have been gained by the grace of his language rather than by the soundness of his views, which are elegantly stated but rarely stable when they look to either side of the beaten track of accepted principles. He wrote violently against French music and the French language as a musical medium, being prominent in the literary disputes known as the "Guerre des Bouffons," but recanted when Gluck's genius was exercised on French opera. Rousseau produced some slight musical dramas, but proof has been adduced that they were the works of other hands.

Martini. Padre Martini (1706-1784) worked to far higher purpose than the last named, and the deeper impression he made on music is due to the depth of his knowledge. He was a mathematician and a scholar in other branches of learning, all of which he brought to bear upon his musical studies. He composed for the church and for the theatre vocal and instrumental chamber music, and pieces for the organ. He enunciated no new theory, but rendered great service by the collected publication of many art rarities exemplifying the musicianship of earlier times, and proving his ability to estimate their merit by the inclusion of a large number of canons of his own, which latter are presented in the enigmatic form of ancient use wherein the primary part or parts alone are given, and the reader has to discover the canon that fixes the period and the interval at which the response is to enter. He issued at different dates three volumes of a *History of Music*, and did not live to complete the fourth, which would have brought the subject only down to the Middle Ages. He was revered by the musicians of all lands, and he is honoured by those of our own time for the penetration with which he discovered the excellence of the boy Mozart, and the encouragement that aided largely to confirm the self-reliance of this everlasting prodigy.

Keiser and his influence. German opera owes its birth to Reinhard Keiser of Weissenfels (1673-1739). His first dramatic effort, *Ismene*, was produced at the court of Brunswick. Success induced him to further exertion in the same field, and its continuance enabled him to undertake the management of the Hamburg theatre, in which, between 1694 and 1734, he produced 116 operas. Even these were but a portion of his works, for he wrote several dramatic oratorios, and made more than one setting of *The Passion*, which last preceded the compositions of the class by Handel and Bach. Little of his music survived him, but his influence on the art of his country was enduring. Matthison distinguished himself in Keiser's theatre, which also was the scene of the young Handel's first dramatic essays. Karl Heinrich Graun, a singer, and Johann Friedrich Agricola belong to the next generation of writers of German opera, both of whom won large renown.

Progress of music in Italy. It is now time to revert to dramatic music in Italy. Giovanni Battista Buononcini (1672-1750) and his brother Marc Antonio were famed in and out of their own country. They both visited London, where the former opposed Handel, and the rivalry between the Italian and the German musician is notable in the history of the time. Nicola Antonio Porpora (1686-1767) owes his fame more to the success of his pupils in singing, of whom Farinelli and Caffarelli were the most distinguished, than to the merit of his numerous compositions. Leonardo Leo

(1694-1746) wrote largely for the stage, but is most prized for his church music, which is of a character so different from his other productions that he is entitled to the twofold estimation of being a light and a severe composer. Johann Adolph Hasse (1699-1783), though born in the neighbourhood of Hamburg, wrote all his many operas, except the first, to Italian words for Italian singers, and may therefore be best classed among the composers of that country, where also he received his musical education. His excellence as a tenor singer, his skill as a clavecinist, and his marriage to Faustina Bordogni, the renowned vocalist, all helped to bring him and his music into note. His remark, when at the age of eighty he superintended the production of his last opera at Milan coincidently with Mozart's bringing out of his *Ascanio in Alba* when fourteen years old, that "this youngster will surpass us all," says as much for his penetration as for the diffidence of one who had passed a long life with success. Giovanni Battista Gesi (1710-1736), being born at Pergola, was called by his schoolmates Il Pergolese, and is known by all the world under this instead of his family name. Little acknowledged while he lived, he accomplished during his almost momentary career such work as places his name among those of the most famous of his countrymen. His comic opera *La Serva Padrona*, little noticed when first given in Naples, had such success when reproduced in Paris that it was shortly afterwards played in every country in Europe. If this piece did not initiate it confirmed the application of music as much to subjects of real as of heroic life, and therefore, though slight in structure and brief in extent, it is historically conspicuous. This and his setting of the *Stabat Mater* for female voices, which occupied him during his last illness, are the compositions by which he is best remembered. Nicolo Jomelli (1714-1774) was born and died in the Neapolitan territory; he produced many operas in Naples, several in Rome, Bologna, and Venice, and he held for fifteen years an engagement in Stuttgart, where his genius was active; he is particularly esteemed for his expression of sentiment, in which quality some of his critics account him the forerunner of Mozart; much as he wrote for the stage, his predilection was for church music, but the amount of his erudition or his power to apply it scarcely justified this preference. This composer may close the present list, as being the first to break through the example of Alessandro Scarlatti, and to write airs without the "Da Capo" which general approval of that example had rendered conventional if not indispensable. The plan claims respect as proving and fulfilling design, but it is inconsistent with truthful treatment of a subject which naturally proceeds in a continuous course and does not admit of the plenary recapitulation of feeling that has already been developed after this has passed into a different direction; as a matter of effect, the "Da Capo" is rarely charming and often tedious, it is less inappropriate in instrumental than vocal music, and even there some modified allusion to previously stated ideas is far more interesting than the unqualified restatement of what has already been set forth. One characteristic must be named that marks the whole period under present survey—the subordination of dramatic propriety to the display of vocal specialities; these were classified in distinct orders, and custom became tyrannic in exacting that every singer in an opera should have an aria of each class, and that the story must be so conducted as to admit of their timely or untimely introduction. The entire action of the Italian opera of the period is conducted in spoken recitative, with few exceptions of accompanied recitative in the most impassioned situations, and the arias or rhythmical portions of the work are episodical, being expatiative or reflective on the circumstances. The volubility that then was esteemed the main, if not the highest, qualification of a vocalist had its imperative exercise in all works for the stage, and the original purpose of dramatic music was thus foiled in making the business of the scene to wait upon the exhibition of the representative.

Instrumental music now began to assume the importance which at present it holds by universal suffrage. Compositions for the organ by Italian and German masters had been numerous, but executancy on bowed instruments was little advanced, and music written for them was accordingly limited in its style and construction. Vivaldi has been named as a pioneer in the art of design, and to the precedent set by him must be attributed the power of unfolding and arranging musical thought which gives to the orchestral and chamber works of after time a supreme position as intellectual and imaginative exercises. The name of Arcangelo Corelli (1653-1713) figures prominently Corelli. in the annals of violin playing, but, whatever the merit of his tone and his style, he employed but a limited portion of his instrument's compass; and this is proved by his writings, wherein the parts for the violin never proceed above D on the first string, the highest note in the third position; it is even said that he refused to play, as impossible, a passage which extended to A in altissimo in the overture to Handel's *Trionfo del Tempo*, and took serious offence when the composer played the note in evidence of its practicability. His compositions are still highly esteemed; they consist of *concertos*—a term which at the time defined concerted pieces for a band, not, as now, pieces for a solo player with orchestral accompaniment—and sonatas, some for one, some for two violins with a bass; they are melodious, but their harmony is not always pure, and, strange to say, though they were written in Italy, where the laws of rhythm and accent were first established, these are slighted in the music; indeed, the longevity of Corelli's works must be due to some other cause than their merit.

Giuseppe Tartini (1692-1770) greatly advanced the Tartini. art of the violinist, as is testified by his compositions for the instrument and his treatise on its capabilities, and is further proved by the eminence of many of his pupils. Tartini contributed to science as well as to art in his discovery (1714) of "resultant tones," often called "Tartini's tones," and yet some writers ascribe the first perception of the phenomenon to Storge, a German, who described it sixteen years later. The phenomenon is this:—when any two notes are produced steadily and with great intensity, a third note is heard, whose vibration number is the difference of those of the two primary notes. It follows from this that any two consecutive members of a harmonic series have the fundamental of that series for their difference tone—thus, $\frac{E}{C}$, the fourth and fifth harmonic, produce C, the prime or generator, at the interval of two octaves under the lower of those two notes; $\frac{E}{G}$, the third and fifth harmonic, produce C, the second harmonic, at the interval of a 5th under the lower of those two notes. The discoverer was wont to tell his pupils that their double-stopping was not in tune unless they could hear the third note; and our own distinguished player and teacher Henry Blagrove (1811-1872) gave the same admonition. The phenomenon has other than technical significance; an experiment by the Rev. Sir F. A. G. Ouseley showed that two pipes, tuned by measurement to so acute a pitch as to render the notes of both inaudible by human ears, when blown together produce the difference tone of the inaudible primaries, and this verifies the fact of the infinite upward range of sound which transcends the perceptive power of human organs. The obverse of this fact is that of any sound being deepened by an 8th if the length of the string

or pipe which produces it be doubled. The law is without exception throughout the compass in which our ears can distinguish pitch, and so, of necessity, a string of twice the length of that whose vibrations induce the deepest perceivable sound must stir the air at such a rate as to cause a tone at an 8th below that lowest audible note. It is hence manifest that, however limited our sense of the range of musical sound, this range extends upward and downward to infinity.

Pianoforte.

The pianoforte owes its invention to the period now under review. This instrument may be styled the voice of the musician, the only means whereby unaided he can give complete utterance to his thoughts, the only vehicle for the communication of musical ideas in their entirety. This is not said in depreciation of other instruments of various excellence which have qualities impossible to the pianoforte, but has reference to the totality of musical speech that is possible, and to the convenience with which this is produced on the instrument in question. The characteristic difference between this instrument and earlier ones of a similar class is that the strings of the pianoforte are struck by hammers impelled by the keys under the performer's finger, and yield louder or softer tone according to the force he uses, whereas its predecessors yielded variety of loudness only by mechanical instead of personal means, and hence were not the living exponents as it is of the executant's impulse. Whether one speak of the happiness kindled in the homestead by this most facile and most self-sufficient instrument, or of the fuel of such happiness, namely, the measureless amount of music of every style and quality that has been written for the pianoforte, its existence is to be accounted as an influence all but infinite upon society as much as upon art. The term "pian e forte" is applied to a musical instrument by Paliarino or Pagliarini, a manufacturer of Modena, in 1598, but no particulars have reached us of its structure or effect. Some instruments which foreshadow the chief essentials of the modern pianoforte, made by Bartolomeo Cristofori, a Paduan then working in Florence, are described in letters of 1709, and must have been made some years earlier, and pianofortes by this ingenious inventor still exist bearing date 1720 and 1726. Marius, a Frenchman, submitted plans for an instrument with hammer action to the Académie Royale des Sciences in 1716, and Schröter, a German, claimed to have devised two models in 1717 and 1721; but the first pianofortes made away from Italy were by Gottfried Silbermann in 1726, who worked from the designs of Cristofori.[1]

Dramatic concerted music.

Let us now revert to the opera, in which vast modifications were germinated towards the middle of the 18th century, and ripened before its close into noble maturity. Allusion has been made in the notice of Pergolese to the appropriation of the lyric element to comic subjects. At first wholly unregarded as a sphere for art uses, then admitted for interludial purposes in a fabrication styled *intermezzo* that was played between the acts of a serious composition, comedy became in course of time the basis of the most highly important, because the most comprehensive and truly the grandest, and further because the most especially musical, application of the art to dramatic ends. The class of writing here to be considered is that structure of concerted vocal music through which a continuous action proceeds, involving the embodiment of the characteristics of the several persons concerned, with their opposition and combination. Handel had been remarkably happy in uniting in one piece the utterances of three, four, and even five distinct persons; he did not, however, make these several individualities interchange speech in dialogue, but caused them to sing, as it were, so many monologues at once, each independent of the others, and Handel was not singular in his occasional practice though he was in his excellence. Nicolo Logroscino (1700-1763), a Neapolitan, who never would write but to the dialect of his own country, was so exclusively comic and so surpassingly successful as to gain the cognomen of "Il Dio dell' opera buffa." It was he who first enchained a series of pieces (technically styled movements) in unbroken sequence, during which different persons entered or left the scene, discoursed in amity or disputation, or united either in the outpouring of a common sentiment or in the declaration of their various passions. For some time this form of lyrical dramatic art was only applied to comic subjects; Paesiello is said to have been the first musician who introduced its use into serious opera; it reached perfection under the masterly, magical, nay, superhuman touch of Mozart, whose two finales in *Figaro* and two in *Don Giovanni* are models which should be the wonder of all time and yet can never be approached. The spoken drama is limited to the onefold utterance of a single person, for, however rapid the colloquy, if any two spoke together, each would eclipse the other's voice—retort may be instantaneous, but cannot be simultaneous. In a painting the different characters and emotions of the persons presented are shown at once, but, as if under the glance of Medusa, they are fixed for ever in one attitude with one expression. In an opera finale the manifold passions of as many human beings, vivified by the voices of the same number of singers, come at once on our hearing with prolonged manifestation, and this is the wielding of a power that is not in the capability of any other of the fine arts.

Gluck.

Christoph Willibald Gluck (1714-1787) was a Bohemian by birth, and a wanderer by habit. He was a grand reformer, or rather restorer, of dramatico-musical art, yes, and a prophet, for he not only revived the principles enunciated in Florence on the threshold of the 17th century, which had been superseded by the vocalisms that had usurped the throne of truth, but he fully forestalled by this revival all that is good in what is nowadays denoted by the cant term "music of the future." As was the wont of his age, Gluck went to extend his art experience, perhaps to complete his education, to Italy, and there produced so many meritorious works in the style of the time as to establish a high reputation. This led to his engagement to write for the Italian Opera in London, whither he came in 1746. The work he composed for this occasion and one he then reproduced met with small favour, and a "pasticcio" from his previous works, *Piramo e Tisbe*, had no better fortune. The failure brought the conviction that, whatever the abstract merit of music, a piece that was appropriate to one character in one situation could not be fitted to another personage under different circumstances, and that admired pieces culled from different works could not be concocted into a whole with appearance of unity. Gluck therefore resolved to abandon the prevailing customs in writing for the stage, and to devise a system of dramatic composition wherein the musical design should grow out of the action of the scene, being ever dependent upon and illustrative of it, and yet being always a design faithful to the principles of what may be named musical architecture. As did Monteverde and his contemporaries, so did this composer aim to distinguish his dramatic persons by assigning music of different character to each; he required that the overture should announce the cast of feeling and thought that was to pervade the work, and he strove to make the whole of the music appropriate to the individuals, to the situations in which they were concerned, and to the

[1] These dates have been gathered and verified by Mr A. J. Hipkins, to whose exhaustive papers on this class of instruments and their best esteemed makers readers are referred. See also PIANOFORTE.

words they uttered. He did not reject the essential of rhythmical melody, which is ever necessary to a musical work, and which stands in relation to passages of pure declamation as metaphor in poetical speech stands in relation to circumstantial statement. An orator will pause in the disclosure of facts to enforce them by the mention of a similitude, or brighten them by reflexions from his own mind, and it is an application of the same art when a character in a drama stays to comment on the scene in which he is involved, and show in words the passion that is seething in his heart. Analogous to this is the occasional arrest of intercourse between the musical persons for the expression of the feeling by which one is swayed, and such is a song in an opera during which, if the action be stagnant, the character more than elsewhere proves its vitality. Plan in a musical work consists (1) in uniform or contrasted rhythm, (2) in the relationship and enchainment of keys, (3) in the development and elaboration of phrases, and (4) in their occasional recurrence. Some plans have by frequent appropriation become to a great extent conventional, and their philosophic basis accounts for and justifies the fact that much music is framed upon them; it is the special province, however, of the writer for voices, and still more so of the writer for the stage, to ignore convention, though never to neglect design, and to construct his plans according to the situations they are to fill and to the materials with which he has to work. For sixteen years Gluck pondered the prevalent improprieties and the possible proprieties of dramatic art, and prepared himself by technical study and polite conversation to strike the blow which was to effect a revolution, the while, strange to say, he wrote several operas in his old style for production in different towns of Italy, Germany, and other countries. At length in 1762 what he meant to be the representative work of his then matured principle, *Orfeo ed Euridice*, appeared in Vienna and made strong impression. Some lighter pieces filled the interim between this, which without exaggeration may be regarded as an event in musical history, and the production in the same city of *Alceste* (1767). The opera was published, as also was *Paride ed Elena* (1769), each with a statement of the artist's views; and these two essays have since been regarded as constituting a grammar of dramatic music. Gluck was not content with the Viennese reception of the works on his new model, and was less so with the accessories that city afforded for giving theatrical effect to his compositions. He went, therefore, to Paris, wrote music to an adaptation of Racine's *Iphigénie en Aulide*, which fulfils his purpose in a higher degree than his previous pieces, and brought it out with extraordinary success. *Orphée* (1774), *Alceste* (1776) (both rearranged from the Italian versions), *Armide* (1776), and lastly *Iphigénie en Tauride* (1779) rose each to a loftier level, and met with just acceptance.

Musical wars. It must be owned that other forces concurred with musical merit in Gluck's Parisian triumphs. He had taught singing to Marie Antoinette before she became dauphiness, and she now was an ardent partisan of her former instructor. Mme. Du Barry held a rival court to that of the young princess, her jealousy of whom and of her state was evinced by every possible means. Accordingly she invited to Paris Nicola Piccini (1728-1800), and strove to establish him in opposition to the German master. His *Roland* set to a libretto by Marmontel was brought out in 1777, anticipating the subject of Gluck's *Armide*; it was followed by other French operas, and the contest ended with the production of his *Iphigénie en Tauride* (1781), subsequently to that with the same title, the masterpiece of his opponent. This musical warfare much resembled that of some forty years earlier between Handel and Buononcini in London, when the king headed the partisans of the German and the Prince of Wales those of the Italian artist; but the Parisian feud was waged with far the greater violence, for, not only were the courts of the two ladies involved in it, but every literatist of note sided with one or the other faction, and hurled poems, or pamphlets, or essays, or critiques at his antagonists, that were crammed with remorseless invective. It pretended to be a dispute as to national style, but was a quarrel between two leaders of fashion. Piccini's music is marked by the melodious grace for which his country claims pre-eminence, Gluck's by the graver thought by which the Teutonic muse is more distinguished. Gluck, however, was not profound, he was no contrapuntist, and his often grand and always expressive harmony sprang more from intuition than knowledge; Piccini had dramatic power, and he advanced greatly Logroscino's invention of continuous concerted music conformable to the business of the scene, but applied this only to comic operas, and so turned it to no account in his compositions for Paris. His most successful production, *La buona Figliuola* (1760), passed from its birthplace, Rome, to every European capital, and is not even now forgotten.

Symphony. The origin, development, and supreme importance of the *symphony* next claim our attention. The term is and always has been used in Italy to define the instrumental preface, which elsewhere is called an overture, to a long vocal work. Handel and others, early in the 18th century, defined by it an instrumental piece incidental to such a work, generally depicting some supposed action, such as a battle, or a multitudinous entry. The term is also applied to the prelude and interludes in a single vocal piece of however small extent. Its significance is far more comprehensive in the application now to be described. Its nearest analogy among earlier compositions is to what of old was called a concerto, and the two names, derived respectively from Greek and Latin, have at root the same meaning. Like the antecedent concerto, the symphony is a composition, consisting of several movements or self-complete divisions, for a full band; unlike its predecessor, the plan of at least its first movement has in the course of years been so distinctly organized that musicians shrink from applying the definition symphony to any work wherein there is not the aim to fulfil this design. At first the term was loosely employed, for even so late as Haydn's visits to London in 1791 and 1794 the symphonies he wrote for first performance there were sometimes announced as such, sometimes as overtures, and sometimes as "full pieces." Its structural requirements especially connect it with works for the chamber, which, if for one or two solo instruments, are styled *sonatas*, if for three or four or more, *trios* or *quartets*, or what not, according to the number of parts they comprise. The word "plan," always used by that distinguished teacher Cipriani Potter (1792-1871) as meaning musical design, happily, because positively, expresses the arrangement of ideas according to a purpose, to which, being intangible and invisible, the word "form" is but metaphorically applicable. Sebastian Bach, Corelli earlier, and Purcell before them, designated compositions as sonatas which, however, are not modelled on the plan of the modern symphony.[1] Bach in some of his later preludes and in other instances has the incipient germ from which the plan has been evolved, and sonatas by Domenico Scarlatti (1683-1757) comprise movements

[1] The earliest use that has been traced of the term sonata or suonata is in its application to some pieces for the organ by the uncle and nephew Gabrieli, who wrote in Venice towards the end of the 16th century. They form portions of larger works of which the rest is vocal; they are brief, solemn, and slow, and are seemingly designed to pour *sound* in long continuance or in large masses. Similar pieces by early German masters have the same definition, and the next generation extended the plan by appending a quick movement.

wherein it is more developed. These musicians were by no means the first, however, to strike the vein of ore for which divination seems to have been carefully in search long prior to their labours. This justifies the belief that its source is in nature, that it was discovered, not created, by man's genius; and the work of successive generations of artists has been to rear and mature that which, having once been found, is the heirloom of the present and the future. The practice of all ages proves common consent that a musical composition must begin and end in one and the same key, and this statement refers not more to our own time than to that of the ancients, whose modes are comparable though not identical with the keys of modern establishment. Continuance of one key throughout a piece of considerable length would be monotonous; to relieve this, modulation is effected into other keys in the course of a composition. To obtain tonal variety without violence, the choice of alternative keys must be made first and chiefly from those which have the nearest tonal relationship to the primary key. After the harmonic 8th (which is a miniature of the 1st) the harmonic 5th is next in prominence, from this note a chord rises as complete as that of the generator, from this chord a second key proceeds by natural evolution; the note, the chord, the key, are each named the dominant, since dominating, commanding, or defining the tonality of the fundamental note. The key of the dominant is hence the one most often chosen for the principal alternative to the primary key if the latter be major; but the key of the 3d and that of the 6th are occasionally selected instead by a further application of the harmonic system. If the primary key be minor, the choice of the chief alternative key is often made in the contrary direction; the tonic itself is assumed to be a harmonic 3d or else a 6th, and the chief modulation is made to the key at one of these intervals below the original keynote, having reference to the submediant or the mediant as the source whence the minor form of a key is derived. Besides the chief alternative, other keys, more or less frequent, more or less remote, according to the greater or less length of a piece, are also employed in the course of a composition. The distribution of keys constitutes the ground-plan and the elevation of a musical structure; the style of harmony, whether diatonic or chromatic, whether contrapuntal or massive, is its material; the ideas, or subjects, or themes, or phrases, or figures, or—as of late they have been whimsically named—motives, stand for the ornamentation, such as portico, frieze, statuary, and carving, which are sometimes essential in a design. This, then, is a brief summary of the plan of the first movement of a symphony—a first subject in the primary key, which consists of a single idea, or of several connected by tonal identity though melodically distinct; a second subject in the chief alternative key, which also may be onefold or manifold in its matter; and these first and second subjects complete the first part. Thus far has been but a simple statement of ideas, which is here followed by a working of the same matter, drawing from it what varieties of expression it may yield through compression or expansion by means of any or every resource of the musician's art; the second part is aptly often named the free fantasia, because unrestricted to a fixed course of modulation, the composer's creative power being at full liberty as to course of keys and manner of development; then for the first time the music reverts to

a valediction to the hearer. The first movement, always cast in this mould, is succeeded generally by one in a slow tempo, sometimes planned like a first allegro, sometimes otherwise, according to outlines that cannot here be detailed, and this exhibits the sentiment of the artist, as did the preceding his scholarship and ingenuity. Then follows generally (again one must say, for there is no necessary prescription) a movement of lighter character than either of the foregoing, sometimes having the musical shape of a dance such as the minuet, sometimes having an arbitrary plan which still is based upon harmonic, and therefore natural, and consequently philosophical, principles. To conclude, there is a movement that is sometimes constructed like the first and is sometimes as complicated, but in other instances has an arbitrary design. Such is the highest class of musical composition: firstly, because it is wholly musical, springing entirely from the artist's imagination without the prompting of words, needing no words to express its meaning to the auditor, being in itself poetry; secondly, because it may comprise every means within the author's power to wield melody,—counterpoint, harmony, modulation,—all that but for the symphony would be special to the fugue, orchestration, and, above all, the arrangement of ideas in a consistent logical method with reference to principles that are the very foundation of art. Let it be hoped that this outline of the elements, essence, and plan of the symphony justifies the use of the words supreme importance in reference to the class of composition at the outset of these remarks.

Haydn. Haydn (1732-1809) is commonly styled the father of the symphony. If truly, then Carl Philip Emanuel Bach (1714-1788), the second of the many sons of the great Sebastian, stands as grandfather in the genealogy of that species of music; and its remoter ancestry may be traced to all but forgotten men in whose works is certainly a forecast of the plan above described. C. P. E. Bach wrote 18 symphonies, and upon these and upon the instrumental chamber music of the same author, Haydn avowedly modelled the plan of his compositions. The earlier writer had not the profundity of his father, nor the grace of Haydn, but his music represents the transition from one to another use in instrumental writing, and it fixed the plan which, however it may be expanded, can never be disestablished from the canons of art. Haydn produced the marvellous number of 125 symphonies (some of them, indeed, were overtures for theatrical use), besides 77 quartets for bowed instruments (the last one unfinished), 52 pianoforte sonatas, and pieces that are almost countless for various combinations of instruments; and in these one knows not whether to wonder more at the infinite fluency of melody or at the artistic mastery. In summing up the enormous amount of his works regard must also be given to his 3 oratorios, his 14 masses, his operas, and his many detached pieces for one and several voices, and then it is hard to believe that all this can have been accomplished in a single life.

Mozart. Next in chronology as a symphonist stands Mozart (1756-1791). Particular comparison must be made of these dates with those of Haydn, as illustrating the relation of the mighty musicians to each other, and the influence each may be supposed to have exercised on his friend—for warmest friends they were and truest estimators of each other's powers. If the young Mozart profited by Haydn's example, as doubtless he did, the old Haydn learned greatly from Mozart's, for there is so obvious a rise in the character of his music from the beginning to the end of his long career as shows that he was under a continuous course of self-schooling. It is because his was self-schooling, and because he seems to have had no distinct principle of harmony, but to have

experimented without infallible success on every unusual combination he wrote, and because likewise in orchestration his writing often appears to have been tentative rather than proving intuition of an effect and a means for its production—it is for these reasons, in spite of his prodigious command of counterpoint, that he may without disrespect be classed after the man whom circumstances compel us to regard as his rival. Mozart wrote 49 symphonies, some of them in the tenderest years of childhood, and repeated the design in many chamber works for several or for a single instrument. These differ in merit, mainly, it may be assumed, because some were written to meet the exigencies and the limitations of particular occasions; but, every one compelling admiration, the last three are conspicuous among the music of all time for the excellence of each and for their difference in character from one another, and these were composed in less than nine weeks, between 26th June and 10th August 1788, during which interval several other lesser and larger pieces also were produced, some for voices and some for instruments. The symphony in E flat, No. 46, is notable for sweetness and playful grace; that in G minor, No. 47, is a torrent of passionate fervour; and that in C, No. 48 (in England named Jupiter), is a combination that has never been surpassed of all the means possible to a musician. In the final movement of this last, a fugue is wrought on the symphonic plan, which is also the case in the overture to the author's latest opera, *Die Zauberflöte*, a completer fusion than has elsewhere been made of the two most distinguishable art-forms, and the formalism is hidden under the beauty of the ideas.

Beethoven.

History now steps on to the great name of Beethoven (1770-1827), who in his 9 symphonies, his 6 concertos (which are pieces on the same plan with the addition of a part for a solo instrument), and his priceless bequest of chamber music commands the world's adoration. It is the shallow practice of the present day to depreciate his two great predecessors, especially Mozart, in his favour; but comparative criticism is to ill purpose if it can only exalt one master by the dethronement of another. Beethoven enlarged the symphony, in some respects changed its character, and perhaps advanced its consideration; above all, after writing for a while in the idiom of these two masters, he stamped his own individuality upon music. One finds, however, a prototype for each thing critics describe as particularly Beethovenish in the writings of Mozart, so that the manifest originality of the later musician lies in the new aspect given by happy expansion to prior existences more than in the creation of new forms of thought. Though he often strove at fugal excellence, he was a child at counterpoint as compared with the two adults who preceded him, and he lost rather than gained fluency in this branch of art as his life proceeded. The ideas of a great artist bear the impress of his age, which is remarkably the case with the musical thoughts of Beethoven, and as his age was nearer to our own, so is his frame of mind more congenial with that of present hearers than are those of Haydn and Mozart. The figure may be reversed; the individuality of an artist is the matrix in which the feelings and thoughts of his age, and still more of the age that next follows him, are moulded, but there must be affinity of temperament between the one and the many for this interchange of impressions to be possible. We of to-day have Beethoven and the consequences of Beethoven, and the influences of these have been active in the interval between our time and the period previous to the French Revolution; and the political, moral, and artistic changes that have been wrought by the ones upon the many as much as by the many on the ones indispose us to the recognition of the beautiful under its earlier aspect. Let us delight in Beethoven—who can fail?—but let us also love Mozart and revere Haydn. Two points are notable in Beethoven's instrumental music—(1) the linking together of the several movements of a work which usually are separated by an interval of silence; but such union is in some of Mozart's early symphonies and some also of Emanuel Bach's; (2) the expression of feelings excited by subjects external to the music and entitling works accordingly, as *Sinfonia Pastorale*, and sonata, *Les Adieux, l'Absence, et le Retour*; but Dietrich Buxtehude of Lübeck had a century earlier produced seven pieces characteristic of the seven planets, and Vivaldi had represented the four seasons in as many concertos, to say nothing of the chaos which opens Haydn's *Creation*. Beethoven's professed purpose in this last particular was to give utterance to impressions rather than to present pictures, and such is the legitimate scope of music, which is not an imitative but an expressive art.

Subsequent symphonists

Next in time came Spohr (1784-1859), whose deliciously-phrased rich-toned symphonies have lost regard in late years, but not beauty. Of his seven symphonies, four bear titles which refer them to an objective purpose; but they are still subjective, for the personality of the writer is expressed in every bar. Mendelssohn (1809-1847) did less but achieved more than Spohr; far less numerous, his instrumental writings for the concert-room and for the chamber have vitality and permanence which are not in those of the other master; they belong as much to hereafter as to now, while those of Spohr are already of the past. Mendelssohn too made musical pictures, owning that "as Beethoven had opened the road it was impossible not to follow;" his two finest symphonies, those in A and in A minor, represent, though not so entitled by him, his impressions of Italy and Scotland, and his characteristic overtures are translations into sound of the poems after which they are named. He also, in more than one instance, joined the several movements of a work, and he employed other devices—his own by felicity of appropriation more than by first use—for enforcing the relationship of the several portions of a musical structure. Schumann (1810-1856) has suffered through the persistence of his partisans in comparing him with another instead of displaying and extolling his own merit. Party spirit and the opposition it kindles has passed, and the delicacy, often subtle in its refinement, the grace, the deep feeling, the ingenuity, but rarely grandeur, that mark his symphonic and chamber music, are now fully perceived. Johannes Brahms is a living worker in this class of art who has already planted his foot in the future and given warrant for transmitting to the coming generation the great model he received from the past, which, because of the masterpieces that have been cast in it, justly bears the name of classical. Cherubini (1760-1842) is the one Italian known to have written a symphony, and this work gives small reason for regret that it stands thus alone; he arranged the same as a violin quartet and wrote two original pieces of this class. Méhul (1763-1817) is the French representative of the symphonic art best known and best esteemed.

English symphonists

The Englishmen who have best succeeded in this highest form of music are Dr Crotch (1775-1847), Cipriani Potter, J. Henry Griesbach (1798-1875), Henry Westrop (1812-1879), and Sterndale Bennett (1816-1875). The last-named cannot be passed with a mere mention. The wide recognition of Bennett's genius at home and in Germany distinguishes him; far more so does the quite individual charm of his music, and most of all does the tender age at which he wrote his best works and the facility with which he produced them. Three of his pianoforte concertos, one of his symphonies, and four of his concert overtures may be cited as representative pieces, wherein sometimes the plan, always the

phraseology, and, in those for the pianoforte, the treatment of the instrument are peculiar to the author in sweetness and elegance; the eternal riddle of the beautiful is propounded in every cadence, and still defies analysis, still remains unsolved. As living writers in this department, Aguilar, Banister, J. F. Barnett, Cowen, Davenport, Walter Macfarren, Hubert Parry, Prout, Stanford, Stephens, and Sullivan must be named.

Instrumentation.

To have spoken of orchestral music compels notice of instrumentation as an element of the art that has high significance. It is analogous to colouring with the painter, being extra to the composition or plan of his work, but essential in vivifying and varying its effect. Its root is the appropriation of passages to the capabilities of instruments for which they are designed, and this is planted in the earliest as much as the latest essays in composition. Its trunk and branches are the combinations of voices and instruments of the same or different qualities of tone, so as to give greatest prominence to the chiefest parts in a musical texture, so as to produce effects of sound which cannot be yielded by the means separately used, but are liable to infinite diversity from the manifold compounds in which they are clustered, and, most of all, so as to secure distinctness of every part in the complex woof which strikes the ear as onefold. Instrumentation may be styled the chemistry of sound, which by the synthesis of distinct tones produces new organisms; it is the blending of any of the rays of the musical prism which produces previously unheard colours. Mozart was the first to evince the very fine sense which perceives the parity and disparity of qualities, how some sounds will mix with and some will penetrate through others, how some instruments by pouring forth a stream of harmony may enrich or nourish a melody that floats on its surface in another quality of tone. Prior musicians had used instruments in alternation for variety of effect, or in combination for the sake of loudness; but it was Mozart that both originated and perfected instrumentation as above described, and it has been practised with more or less success in so far as his principles have been fulfilled, with more or less failure in so far as his principles have been abandoned. In two centuries instruments have undergone large modification, and their treatment has been modified accordingly. Writing for the harpsichord is widely different from that for the pianoforte, which also has been changed in character from generation to generation of composers, not only because of improvements in the manufacture of the instrument, but because of enlarged insight into its capabilities; hence the music of Emanuel Bach, Mozart, Dussek, Beethoven, Clementi, Cramer, Hummel, Moscheles, John Field, C. M. von Weber, Mendelssohn, Chopin, Schumann, Liszt, Thalberg, Sterndale Bennett, and Anton Rubinstein forms a continuous scale of development in aptitude and diversity. The transformation of the viol of various sizes into the violin, violoncello, and double bass of present use is a subject for special history, but its course is inseparably associated with the names of the great Cremonese manufacturers, Andrea Amati (1540), his two sons and his grandson, the family Guarnerius, and Stradivarius, who all practised their craft as an art more than as a trade, setting each the stamp of his own genius on the instruments he produced and leaving models that have never yet been equalled. The extended resources of bowed instruments have come wholly through extended skill of executants, especially of Viotti, Rudolphe Kreutzer, Rode, Baillot, Paganini, Spohr, De Beriot, Molique, Ernst, Blagrove, Sivori, Sainton, Vieuxtemps, Joachim, and Carrodus on the violin; of Crosdill, Cervetto, Lindley, and Piatti on the violoncello; and of Dragonetti and Bottesini on the double bass. The entire construction of flute and reed instruments was changed by Theobald Boehm (1794-1881), and all makers now work upon his principle. Facilities have been increased on each of these classes of instruments, but on horns and trumpets modern use has in some respects diminished them; that is, employing only notes of the harmonic scale, players of the time of Purcell, Handel, and Bach practised so constantly in the upper register that they easily produced the 12th harmonic and above this sometimes notes up to the 18th, and these they executed with volubility akin to that displayed on fingered instruments; it is now the custom to exercise the lips on the lower notes and on longer continued sounds, and hence the passages written by the elder masters are difficult to the verge of the impossible to present practitioners, and a totally different character distinguishes modern from earlier music for brass instruments. On the other hand, Charles Joseph Sax (1791-1865), and far more his still living son Adolphe, have devised such systematic changes in the fabrication of all brass instruments as to give them an entirely new place in the orchestral category; by means of the pistons of their sax-horns, cornets, and the like, these instruments yield the complete chromatic scale, which, superficially, appears to be an advantage; but, save for military bands, the alteration is a serious evil and has an incalculably pernicious effect upon the orchestration of the day. This strong but careful statement is justified by the beautiful effects in music written earlier than the use of valves, from the characterization, firstly, of particular keys in a musical composition; secondly, of certain chords in the keys; and, thirdly, of special notes in each of these chords through appropriation to them of selected sounds from the limited harmonic series, whereas composers who apply Sax's invention to orchestral use reduce the band to a one-toned machine that has the same quality throughout its range. Let proof be drawn from example; in the andante in A flat in Beethoven's symphony in C minor, the horns and trumpets are crooked in C, they can therefore be used but for peculiar notes in the primary key of the piece, but they give especial tone to the key of C, into which the music thrice modulates, that distinguishes it from the entire context; in the finale of the same master's symphony in F the return to the primary key from the remote tonality of F sharp minor is marked by the tone of the F trumpet, whose keynote is the enharmonic of the E sharp of the foregoing harmony; and yet again, in the "dona nobis" of the same master's mass in D, the phrases for the trumpets in B flat are distinguished from what surrounds by the tone and the key, and thus give technical significance to the author's purpose, "a prayer for peace in the midst of war." Inability to resist the temptation of the semitonic scale, and so to use "sounding brass" as freely as instruments of more delicate tone and greater natural volubility, is exemplified in the writings of many a living musician, and regretted by many of his admirers.

Opéra comique, singspiel, ballad opera.

A class of opera, defined in French as *opéra comique*, dates ostensibly from 1715. The definition is unsound, because, whatever the subjects of the first pieces so styled, it is often applied to works of a romantic, serious, or even tragic nature. The separation of this from the grand opéra lies in the latter having music throughout, its rhythmical pieces being divided by accompanied recitative, while the opéra comique consists of music interspersed with spoken dialogue. The distinction arose from what was considered an infringement of the patent of the Parisian Opera House by a company who performed musical pieces at the Théâtre de la Foire, and an agreement between the two establishments was authorized at the date above cited to the effect that the assumed intruder must have speaking in every piece it presented. The name of Rameau is the earliest of note among composers of this class of work, and his success in *L'Endriague*

(1721) and *L'Enrolement d'Arlequin* (1726), which were comical enough in plot to sanction the definition, procured hearing for his larger and graver dramatic efforts. Most conspicuous of those who later have gained fame as composers of opéras comiques are Monsigny, Dalayrac, Grétry, Méhul, Boieldieu, the profound Cherubini, Halévy, Auber, Ambroise Thomas, and Gounod, many of whom also produced masterly pieces in the other class of opera. The *singspiel* is the German parallel to the opéra comique, and its examples comprise some of the greatest works that adorn the lyric stage. Among these are the *Entführung aus dem Serail* and the *Zauberflöte* of Mozart, the *Fidelio* of Beethoven, which stands above comparison with all dramatic music save only the *Figaro* and the *Don Giovanni* of Mozart, and suffers not in being placed side by side with these prodigies of genius and mastery, the *Faust* and the *Zemira und Azor* of Spohr, the *Freischütz* of C. M. von Weber, and *Heimkehr aus der Fremde* of Mendelssohn. It was a novelty of Weber to break from set forms in his dramatic monologues and frame from the promptings of the situation a special plan for each, which has frequent variations of tempo but always coherence of key, and which never fails to manifest a conceived and fulfilled design; and this successful innovation, as much as their musical merit, gives historical importance to his works for the stage. Spohr, with *Jessonda* (1823), was the first to appropriate continuous music with full orchestra to the German stage, and he wrote in the journals to defend his innovation, which had been preceded in Italy by Rossini with *Otello*, wherein the "recitativo parlante" was for the first time in that country discarded. Spoken dramas profusely interspersed with music and called operas have had vogue in England since the time of Purcell, whose genius was cramped by the literary conceit that music was unfit for expression of human feelings on the stage. The principle was superseded, but the form resulting from it was preserved in the *ballad operas*, which from 1727 for more than a century were the sole vehicles for music in our theatres; but these had the speciality that for the most part their music consists of the popularities of the day and rarely includes original composition. Dr Arne, Stephen Storace, Shield, Dibdin, and Sir H. R. Bishop wrote all the music for pieces of this class, and the last appropriated, or modified, or restored to its pristine form the glee in his dramatic works, and by specimens of this he is and will be chiefly remembered. In 1834 a new impulse was given to English opera by the warm welcome of John Barnett's *Mountain Sylph*, which, though it has speaking, is far more essentially musical in structure than its predecessors, and it has been followed by many a work of merit by the same hand, by Balfe, E. J. Loder, Wallace, and others, several of these being wholly lyrical, according to the requirements of French grand opéra.

[Mo]dern [Ita]lian [op]era.

Side by side with the activity in other countries just reviewed was the progress of opera in Italy. Important contributors to this were Giovanni Paesiello (1741-1815) and Domenico Cimarosa (1749-1801), who both wrote extensively, succeeded greatly, and impressed the art with their specialities. Of vastly greater consequence in the future was Mozart, who produced many Italian operas, and, of all musicians that have ever composed for the theatre, brought dramatic music the most nearly to perfection in fitness to the scene, delineation of character, and technical design. The name of Rossini (1792-1868) is conspicuous in the history of opera from the once universal fashion to admire his writings, from the new manner of vocal flourishes he introduced, which strongly tended to revive the inconsistencies against which Gluck had striven, from the ardent imitators who at the time of his triumphs emulated his peculiarities, from his entire change of style in his later productions, and from his all but ceasing to produce during nearly forty years. The languishing Bellini (1802-1835) and the spirited and far more prolific Donizetti (1796-1848) proved their artistic strength by avoiding the Rossini idiom, but neither can be accredited with asserting a style. Giuseppe Verdi has proved melodic creativeness equal to either of theirs, with a stronger power of characterization and a better regard for the exigencies of the scene.

Opéra bouffe.

A new species of composition has sprung into being within these thirty years, which in France is defined as *opéra bouffe*, and in England as *comic opera*, but is totally distinct from the opera buffa of Italy or the opéra comique of France, while less unlike the intermezzo of Italian use in the 18th century. It may be described as burlesque, sometimes of stories that have held mankind's respect for ages, sometimes of modern social absurdities, but having the ridiculous for its main quality, and extravagant in every essential. It consists of an intermixture of lightest and most frivolous music with spoken dialogue, and depends as much on its literary sprightliness as on its musical tunefulness, for success. It may be said to have been originated by Offenbach (1819-1882) of Cologne, who settled in Paris when young, where in 1855 he engaged a theatre for the production of his lyrical caricatures, initiated them with *Les Deux Aveugles*, and wrote in all sixty-nine pieces. He has several imitators in the country of his adoption, and is represented in England by Sir Arthur Sullivan.

Summary of operatic history.

Operatic history may be epitomized in a few sentences. The Greek tragedy was essentially lyrical, and it portrayed the characters and the incidents with which all who witnessed were intimate. It fell asleep with the other forms of classic art, to be awakened at the end of the 16th century; but those who aimed at restoring it to the active world chose subjects from the antique which stirred the wonder more than the sympathy of their audiences. Regard for the gods and heroes of ancient myths, or for the figures of mediæval chivalry, who were little less outside general familiarity, long gave an artificial air to theatrical writing. It was the comic branch of opera that first broke from the trammels of the pedagogue, and in representing people of its own time applied the grandest attribute of music—the expression of passions common to us all under circumstances experienced by us all in phraseology familiar to us all. In the pieces for the Countess and the Count in *Figaro* Mozart rose to earnestness, and in those for Donna Anna, Ottavio, and the Commandant in *Don Giovanni* still higher to the grandest tragedy, and always on the lips of persons in a period so near to our own that we recognize our own feelings in their utterances. The preternatural is also shown to be within the range of this art in the music of the Statue in *Don Giovanni*, which may confidently be compared for effect with the ghost scenes in *Hamlet*, in answer to those who raise quarrelsome questions as to the relative power of music and speech to embody analogous situations. All musicians since Mozart have chosen subjects, however serious, from modern history or from still later modern life, and the preternatural has exercised the imagination of Spohr, Weber, Marschner, and Barnett, to whom Mendelssohn must be added on account of the fragments of *Loreley*.

Wagner.

During the last thirty years Richard Wagner (1813-1883) has striven to revolutionize the lyrical drama by his polemical writing, by his compositions for the theatre, of which he is the twofold author of words and notes, and by his extraordinary means of bringing these conspicuously before the public. His principles were all gathered from antecedent reformers; their application was his own. His works of art are, by himself and his supporters, professed to be

neither dramas nor music, but this cannot exempt them from dramatic and musical censure. The very remarkable commotion he has made in the world of art might be compared with that excited by the rivalry between Buononcini and Handel in London and that between Piccini and Gluck in Paris, but that these were in each instance the contention between one musician and another, whereas in the present case it is the opposition of one writer to all the musicians in the world, save the few members of the profession who, believing in the man, his doctrine, and his power to apply it, undertake propagandism as a duty, and endeavour to make proselytes to their faith. Wagner's recent death has left judgment free as to his theoretical and practical merit; a few years will determine the permanence or evanescence of his productions, and an article on his name in the present work may be written far enough from now to chronicle the result.

Oratorio. Within the present century the oratorio has undergone large modification, somewhat in structure and more in style. Haydn's *Creation* is planned on the model of the several settings of music to the recitation of the Divine Passion which were frequent from the date of the Reformation till the 18th century was one-third advanced. Its text consists of a Bible narrative interspersed with reflective verses which have no pretension to be defined as poetry. The work was said to have been suggested to the composer by his hearing some of Handel's oratorios during his two visits to England, but it differs in character as widely from these as was natural in coming from a musician whose genius, however great, was wholly unlike that of his predecessor. *The Seasons*, by the same master, has a secular subject which is secularly treated, and in this, equally with the other, the manner of the author, as evinced in his instrumental music, is ever apparent. Beethoven's *Mount of Olives* is in dramatic form, though changed into narrative in several English versions. The portions of this that have most interest are those which are the least sacred—for instance, the chorus of the soldiers who come to seek and then to arrest the Accused of Iscariot. *The Deluge*, by Schneider, is also a drama by a modern hand. It and the *Moses* of Marx have sent only the reputation of their esteem into England. Spohr's three oratorios—especially *Die letzten Dinge*, known here as the *Last Judgment*—bear so strongly the impress of his speciality in the constant prevalence of the chromatic element throughout them, and in the rich but always transparent orchestration, and they were so largely imitated by contemporaries, that they may be said to have opened an epoch which, however, was early closed. Far more important in themselves and in their influence are the two works of the class by Mendelssohn, with which may be associated the *Lobgesang* (Hymn of Praise), written to commemorate the 400th anniversary of the invention of printing. In these the dramatic, the narrative, and the didactic elements all appear, the first so conspicuously and so grandly in consonance with the spirit of the time that it specially distinguishes the works as they do the master who, through them, holds a rank in England as a sacred writer all but parallel to that of Handel. The influence of Mendelssohn's oratorios is obvious in the works of other musicians, and public approval attests it to be an influence for good. Compositions styled oratorios have been produced by Liszt and Gounod which seem to aim largely at novelty, but a future generation must judge whether they have struck the mark. In England, Crotch's *Palestine* emulated Handelian precedent, and stood for long alone as a native production. Many years later Sir Sterndale Bennett's *Woman of Samaria* won wider sympathy. The living writers who have courted and gained fame in England by longer or shorter oratorios are J. F. Barnett, Sir J. Benedict, Sir M. Costa, and Sir A. Sullivan.

Tonic Sol-fa. With some pleasure and some regret must be mentioned the active exertions of John Curwen (1816-1880), a Nonconformist minister, with a large staff of adherents, in the promulgation of a professedly new musical system under the title of "Tonic Sol-fa": pleasure, because of the wide extension of musical study resulting from his indefatigable zeal; regret, because perhaps a larger and certainly a better result would have rewarded like energy in the propagation of musical knowledge in the shape that has grown into maturity through eight centuries, and possesses the whole world's acceptance. He who is honoured as the founder of the system professed to have derived it from Miss Glover of Norwich, whose method he but modified and expanded; but hers was based upon the ancient gamut already described, omitting the constant recital of the alphabetical name of each note, together with the arbitrary syllable that indicates its key relationship, and omitting too the recital of two or more of these syllables when the same note is common to as many keys, as "C, Fa, Ut," meaning that the note C is the subdominant of G and the tonic of C. The notes are represented by the initials of the seven syllables still used in Italy and France as the fixed names of the seven notes; but in "Tonic Sol-fa" the seven letters refer to key relationship and not to pitch. Further, the system has a wholly different terminology from that in universal use. It would be uncandid not to state that many men of greatest eminence outside the musical profession and many musicians support the system; here may only its bare principles be stated and not its merits discussed. A somewhat analogous action has, at the same time, been busy with regard to musical notation in France. Émile Chevé (1804), a surgeon in the French marine service, having married Nanine, the sister of Aimé Paris, learned from her the views of her brother (who had adopted them from Galin) as to another new system of musical notation, and he, Chevé, in 1844 applied himself to its dissemination. The system bears the name of "Galin-Paris-Chevé," and, like the other, refers the notes to key relationship and not to pitch, but employs the first seven numerals as their symbols. This invention, if so it may be called, was strongly discouraged by the most esteemed musicians of Paris, but its advocates persevere in its propagation.

Day's fundamental discord and distinction of style. As a summary of all the precept and example that has been cited in this survey of the centuries let the writer state his convictions on musical theory, which are, that the *Treatise on Harmony* (1845) by Alfred Day (1810-1849) comprehends whatever is practically available, and reconciles the previously apparent discrepancies between principle and use. The laws of the primitive diatonic style had never been repealed; the discovery by Noble and Pigot of generated harmonics had been held as belonging to science and not pertaining to art; composers had employed what may be classed as natural in distinction from arbitrary combinations, but each only on the prompting of his own genius and only with the justification of their effect. The author now cited was the first to classify the ancient, strict, uniform, diatonic, contrapuntal style, apart from the modern, free, exceptive, chromatic, massive style, to separate the principles that guide the one from the laws that control the other, and to place a subject that is at once sublime and beautiful in a light of unfailing clearness. He showed that one or another beautiful chord and the progressions thence were not capricious violations of rule, permissible to genius though unallowable to ordinary writers; he showed that such things were acceptable not only because great masters had written them, and so small musicians might repeat the trespass; he proved this by demonstrating the self-perfection of the ancient canon and the also perfect modern system that rests on a basis totally

distinct from that of the other. He classed diatonic harmony, with its uniform treatment of all the notes in a key, into concords which include not the 4th from the bass, and three species of discords, namely, passing notes of several varieties, suspensions resolved on a note of the harmony in which they are discordant, and essential or elemental discords resolved with the progression of the whole chord to a chord whose root is at a 4th above the root of the discord. In this style discordant notes have identical treatment according to the number of their interval (as 7th or 9th), unaffected by its quality (as major or minor). He traced all the notes of the scale available in the diatonic style to the tonic, the 5th below it, and the 5th above it, as their roots, having thus a minor tone between the dominant and submediant in the major form of a key. Present composers with ability for its production may, by observance of this ancient canon, make music in the style of the 16th century with as good likelihood of beauty as had the great masters of that period, but without imitating them, since working by their method and not necessarily by their example. Day showed that peculiar treatment of certain notes of the diatonic scale, together with the inclusion of the chromatic element which has crept into use during the later centuries, constitutes a style totally distinct from the other, and justly to be called exceptional. The basis of this system is the derivation of harmonics from specified fundamental notes or generators in every key. Thus exceptionally the 4th above the bass is a concord, when it is the root inverted above the 5th in the triads of the tonic, the subdominant, and the dominant. Thus exceptionally the 3d in the dominant triad has peculiar poignancy to which modern ears are sensitive, and the dominant triad is imitable on the supertonic by employment of its chromatic major 3d that has the same special character as the 3d of the dominant. Thus exceptionally the 7th may be added to the dominant triad. This combination may also be imitated on the supertonic, and the addition likewise of a chromatic minor 7th to the tonic triad makes another chord consisting of the same intervals as the dominant 7th, namely, perfect 5th, major 3d, and minor 7th, the last two being at a diminished 5th asunder. Again exceptionally the minor or the major 9th may be added to each of these chords of the 7th, the 11th to the chords of the 9th, and the minor or major 13th to the chords of the 11th, beyond which the ascent by 3ds proceeds no more, as the 15th is the double octave of the root. The 9th, 11th, and 13th are susceptible of resolution each on a note of its own chord, which is not so with the 3d and 7th; or they may, like the 3d and 7th, be resolved on some note of another chord when the entire harmony changes. The chords of the 9th, still less of the 11th, and of the 13th least, rarely appear complete, the root being frequently, and other notes occasionally, omitted. In this style the discordant notes (3d, 7th, minor or major 9th, 11th, and minor or major 13th) are identical in quality to whichever of the three roots they belong; but they vary in treatment according to their source; and in these two specialities they are distinguished from diatonic discords. Broadly it may be stated, but subject to amplification, that the natural resolution of dominant discords is upon the tonic concord, that the natural resolution of supertonic discords is either upon a tonic concord or upon a dominant discord, and that the natural resolution of tonic discords is either upon a dominant discord or upon a supertonic discord, the several elements of each harmony proceeding variously according to what note must follow it in the ensuing chord. The term fundamental discords is aptly applied to these which are traced to their harmonic generator, and their pertinence to one key is established by their all being resolvable on chords peculiar to the same tonality. The theory steps a degree further in proving that the harmony of the augmented 6th $^{\sharp F}_{\flat A}$ with its several varieties of accompaniment consists of the primary and secondary harmonics of a common generator, and that the dominant and tonic are the notes in any key whence this harmony is derived, yielding respectively the augmented 6th on the minor 6th of the chromatic scale, and the augmented 6th on the minor 2d. The bold venture of Mouton, repeated by Monteverde and defended by the latter against the fierce disputation of the orthodox, is theoretically justified in this system on the principle of natural harmonics first enunciated in Oxford, and the ingenious searchings after truth by Rameau are shown in this system to have been on a false track and so to have passed round instead of to their mark. Day's *Treatise*, on its appearance, was denounced by the chief musicians in London, and a single believer for some time alone maintained and taught its enlightened views. These have now the acquiescence of many more musicians than originally opposed them, they are upheld by several eloquent supporters, and they are widely disseminated throughout England. They have not yet been promulgated beyond that country; but the advance they have made there in thirty-eight years may be taken as augury of their admission elsewhere when time and circumstance may be opportune for their presentation.

Epitome

Music, in the modern special sense of the word, was with the early Greeks regulated declamation to the accompaniment of instruments with stretched strings that were plucked or struck. With the Greeks it was also produced from pipes of metal or wood or horn, with reeds or without, as signals or incentives in war and for domestic amusement. Far later, and in imperial Rome, it acquired a more definite form of what is now called melody. The transition of its principles from those which ruled in the classic ages to those which had been slowly developed in the course of after centuries is veiled with a mist like that which obscures the setting of paganism and the dawning of Christianity. Many fallacies are still entertained as to the dated organization of music in the church, and none greater than its ascription to St Ambrose and St Gregory, and the credit given to Guido for the enunciation of its rules. From the end of the 10th century music was in England in advance of other nations until its rise in Flanders in the 15th, when still our forefathers kept abreast of their contemporaries. Throughout the ecclesiastical reign of scholarship, the untutored people had a music of their own, which in its tonal and rhythmical affinity to that of later date commands present sympathy, and which, throughout the North, having the element of harmony or the combination of sounds, was the foundation of all to which science and art have together attained. The Flemings planted schools in Rome, Naples, and Venice, and the rise of the art in Germany was due to their influence. Adopted from the people by the church, the art of harmony was reduced to a system under the name of counterpoint. Its artificial ordinances were broken through at the end of the 16th century, against violent opposition but with permanent success. Coincident with this innovation of principles was another innovation in the form of applying them, which was intended as a revival of antique use, but which issued, working together with the first-named change, in the establishment of the modern in music; these two were the discovery of fundamental discords and the originating of free musical recitation. The acoustical phenomenon whereon fundamental discords are grounded was first perceived in England, and this in the last quarter of the 17th century. Empirical rules drawn from the tentative practices of great musicians were from

time to time enunciated; but no theory till that described in the last foregoing paragraph probed the natural principles upon which, unknowingly, masters have wrought, nor distinguished between these and the ingenious artifices whereby in former times musical etymology and syntax were regulated. The development of plan or design in musical composition has been the fruition of the last two centuries, and, in spite of all dispute as to its paramount necessity, hope points to it as the everlasting standard of genuineness in art.

To distinguish allusions to the present time in comparison with former dates throughout this article, and to mark the period to which its narration reaches, statement must be made that it is completed in 1883. (G. A. M.)

PART II.—SCIENTIFIC BASIS.

Musical sounds reach our ears through the air. This is proved by showing that a sounding body placed in a space void of air, as under the receiver of an air-pump, is unable to emit sound. It will be sufficient for our present purpose to admit that musical sounds are transmitted through the air with substantially unchanged quality, even to great distances. The law according to which the apparent intensity of a musical sound diminishes as it spreads itself over an increasing surface of air is as yet uncertain; we can only say with certainty that it does diminish.

The origin of musical sound consists in the regular periodic vibration of some surface in contact with air, whereby motion is imparted to the air, and thus transmitted to the ear. Experience tells us as follows:—

1. Regular repetition is characteristic of those motions which give rise to musical sounds.
2. The pitch of the note produced depends on the time in which the motion takes place.
3. The loudness or intensity of the note depends on the magnitude of the motion and on the pitch.
4. The quality of the note depends on the form or shape of the motion, that is to say, on the manner in which it is executed within the time in which it takes place.

Regularity.

1. Regular repetition characterizes musical notes; irregularity in the movements in successive periods characterizes unmusical noises. This is most usefully illustrated by cases in which *false* notes are obtained. Strings, for instance, sometimes cannot be tuned. In these cases the motion can frequently be seen to be irregular.

Pitch defined by frequency.

2. The time in which the motion takes place is defined conveniently by the number of times the whole motion is repeated in a second. The number which expresses this may be called the vibration number, or the frequency of the note. Pitch, then, is defined by frequency. Notes of different frequencies present sounds to the ear which are essentially different from one another. The physical analogy based on frequency would compare notes of different pitch to light of different colours; this analogy does not, however, extend to the nature of the perceptions. The notes of a uniform instrument present a closer analogy with a definite colour in virtue of their uniform quality, so far as perception goes. And from this point of view there is nothing in the perception of colour analogous to the perception of difference of pitch in music. In speaking of the perception of combinations of notes we shall see that the ear possesses, in a more or less perfect form, the power of analysing combinations and hearing the notes separately. If we admitted the physical analogy between pitch and colour this would correspond to a power of seeing compound colours analysed into their constituents. This of course does not exist. Though we may know by experience what a compound colour consists of, no amount of experience will enable us to see the components separately in the same way in which we hear the notes of a combination separately. The modes of perception are therefore wholly different in the two cases.

When one note is produced by a motion whose frequency is twice that of another, a relation subsists between the sounds of the two notes which appears not to be capable of further explanation. They are said to form octaves with one another. It is easy to give some account of the formation of the octave regarded as a concord, but the inexplicable peculiarity of the relation consists in a sort of quasi-identity between the sounds of the two notes. Many persons cannot distinguish with certainty two notes an octave apart, particularly if the quality of tone employed be one in the use of which the observer is not practised, and this is the case even with ears of considerable acuteness and cultivation; but it does not apply to those ears of the highest class which possess the power of the recollection of absolute pitch. Such ears can usually distinguish octaves with certainty. But in all cases the similarity of effect between notes differing in pitch by one or more octaves will be admitted. It is a purely mental phenomenon, and no explanation can be given of it. If for a moment we recur to the physical analogy of colour simply for the purpose of illustration, the whole range of visible colour corresponds to less than an octave. The musical phenomenon of the similarity of octaves is as if part of the invisible spectrum, say in the ultra-red, excited a sensation having some similarity to the sensation of its octave in the visible spectrum, the two sensations being such that there is a continuous change from the one to the other. Nothing of the kind actually exists in the case of light. The actual impression on the nervous system of the ear which is concerned with the perception of pitch is believed to be substantially the same in different individuals. But the mental processes attached to this perception differ so widely that for all practical purposes the results are different in different individuals. The chief difference appears to consist in the different development of the memory of the actual sound of definite notes, which we may speak of as the perception of absolute pitch. This is developed in all degrees: from almost complete absence, in which case we have a want of musical ear arising from the failure to retain the pitch of a note heard even for the shortest time, to that highest degree of perfection in which the memory retains permanently the sound of every note that is once heard. It is not believed that the possession of this memory is capable of cultivation to any considerable extent. It appears rather to be a natural gift, as it usually appears at once in childhood where it is possessed at all. Roughly speaking, and in the absence of reliable statistics, we may say that the possession of the perception of absolute pitch is distributed as follows:—say 1 per cent. possess it, 1 per cent. are entirely destitute of it, so as to be said to have no ear, and the remaining 98 per cent. or so possess it in a more or less modified form. Of this usual condition we may take as a type cases in which the mental effect of a musical note can be retained in the memory for some minutes.

Perception of absolute and of relative pitch.

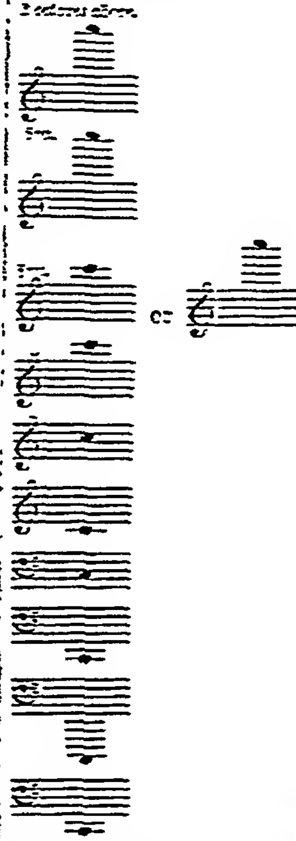
We have to consider the musical perception of the class possessing the power, and of the numerically much larger class who only possess it in a modified form. A simple tune or melody produces the same effect in all cases as far as we know, except that those who have the perception of absolute pitch know what notes are employed, while others are only conscious of the intervals, *i.e.*, of the relative pitch. All the analytical perceptions are as a rule much better

developed in the case of those who possess the perception of absolute pitch than in other cases. In those whose perceptions fall below a certain mark the analysis of combinations of notes by the ear fails more or less entirely. In this particular, however, cultivation is generally possible. And this agrees with the assumption that the mechanism of the ear is generally the same. For the perception of differences of pitch is conceived to be due to a mechanism universally present, which effects the analysis of combinations by the same means by which the pitch is distinguished. The phenomena which give rise to this belief may be stated as follows. If we sound two notes together and cause one of them to change its pitch, we can examine the sensations produced by all sorts of binary combinations. If the two notes have the same pitch at starting, then when they separate beats are heard. Up to a certain point, which is not very far from the point where the two notes are half a semitone apart, the effect in the ear is as if one note was heard, having the alternations of intensity which constitute beats and a pitch generally intermediate between the constituent notes. At this distance of about half a semitone the ear begins to perceive the two separate notes beside the beats. As the distance between the constituent notes increases the two notes become more prominent, the beats grow fainter, and ultimately, when the constituent notes are a little more than a whole tone apart, the beats disappear and the two notes are recognized as separate and distinct sensations.

Now this observation is explained by Helmholtz's hypothesis of the existence of a resonant mechanism in the ear. Just as a harp, or a piano with the dampers raised, will have the strings corresponding to any sound that reaches it set in vibration, so we suppose that there exists a collection of resonant bodies in the ear which respond to vibrations of pitch nearly coincident with their own. The question then arises, Is the range of sympathy, the distance at which a certain response is excited in the vibrating mechanism of the ear, the same in all cases?

It is easily seen that, if the above phenomena are substantially the same in all cases, the character of the mechanism must also be the same. The interval at which the two notes of a binary combination begin to be separately distinguished can be observed with considerable accuracy, and is critical in the matter. So far as such observations have been hitherto attempted, this interval is very nearly the same in persons of the highest type of ear, who have the perception of absolute pitch in an advanced degree, and in persons occupying a position not high among those who only possess the power of relative perception. In all cases, moreover, where beats are observed, the beats are the same to all persons, so far as our present knowledge goes. And as some of these beats arise within the ear itself, they depend upon the properties of its mechanism. The result is that, so far as ordinary observation goes, the main features of the mechanism of the ear may be safely pronounced to be the same,—in the great majority of cases, at all events. Some slight differences in this respect have been observed; but there can be little doubt that the great differences which exist in the endowment of the ears of different persons do not arise from differences in the receptive mechanism, but have their source in the nervous or mental actions which lie behind the mechanism. In this we are not referring to the differences which exist between the range of hearing in different individuals. These undoubtedly arise from what may be spoken of as differences in the compass of the receptive instrument in different individuals. These differences exist both at the upper and lower extremities of the scale. Those in whom the upward range is defective fail to hear the noises of certain insects, and are also unable to hear organ-pipes of very high pitch. The absence of the lower range of hearing is less well established.

The complete range of audible musical sounds comprises about nine octaves. It extends from the 32-foot C, two octaves below the lowest note of a bass voice, to somewhere about three octaves above C in alt. The upper notes of this range are not audible to some persons. Organ-pipes are made having notes covering this whole range, except about the top half-octave. The position of notes is so frequently referred to the length of the corresponding organ-pipe that it is convenient here to give these lengths, with the usual notation for the notes to which they correspond. Range of musical sounds.



C''''''''		¾ inch.
C'''''''		1½ inches.
C''''''	c in altissimo.	3 inches.
C''''	c in alt.	6 inches.
C'''	c treble.	1 foot.
C''	c middle.	2 feet.
C'	c tenor.	4 feet.
C	Great c.	8 feet.
,C or $\underline{C}$		16 feet.
,,C or $\underline{\underline{C}}$		32 feet.

N.B.—The letter notation is continued from each C upwards through the octave, and changes at the next C above.

The normal perception of pitch does not, however, cover all this range. Its extent varies much in different individuals. We cannot assume that pitch can be completely perceived in the normal manner in either the uppermost octave or the lowest octave of the foregoing range. The lower half of the uppermost octave is easily examined, wherever an organ is available, by drawing the fifteenth alone and sounding the notes of the upper half octave of the keyboard. These notes will generally be heard as sounds, but if a bit of a melody be sounded on them, for instance a simple scale passage, it will generally be found unrecognizable. The same is the case with the lowest octave lying between the 16-foot and 32-foot notes. There has been considerable doubt as to the reality of the notes which profess to occupy this position. All instruments sound notes of a complex character, which include sounds of a higher pitch than the nominal note, in fact the harmonics, of which the nominal note is the fundamental. And doubts have been raised, which have in some cases proved to be well founded, whether the deep notes in question really contain any of the nominal note or fundamental at all, and do not rather consist entirely of harmonics, or of sounds whose real pitch is much higher than the nominal one.

These doubts have been settled in the case of the low notes of the organ by the process of analysis by beats. Where two notes differing slightly in pitch form beats, the number of beats in a second is equal to the difference of the frequencies. If, then, the frequencies of the notes sounded differ by one vibration per second nearly, there will be one beat per second; if they differ by two or three per second there will be two or three beats. The frequencies of the two lowest notes of the 32-foot range are sufficiently nearly—

$$C = 17$$
$$C\sharp = 18.$$

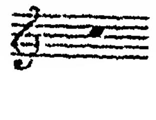
If, therefore, C and C♯ are true notes they should give about one beat per second. The octaves of these notes give about two beats per second, and the twelfths give about three beats per second. The notes of large-scale open 32-foot pipes when thus tested give one beat per second. The notes of stopped pipes vary very much according to the scale and voicing, but in these low notes no fundamental has as yet been detected. They always present the three beats characteristic of the twelfth.

This is contrary to the statement, long accepted on the authority of Helmholtz, that large-scale stopped pipes give nearly pure tones. It does not appear that that statement was ever verified, and it appears not to be correct. 32-foot stops are not very common, but these principles can be illustrated with 16-foot stops. Here the fundamental beat is about two per second, the octave four, and the twelfth six for adjoining semitones at the bottom of the range. The same results are easily found. As a rule the large open 16-foot stops of the pedal give their fundamentals quite pure, while stopped pipes professing to speak the same notes almost invariably present the six beats of the twelfth, sometimes with and sometimes without fundamental. The conclusion we may draw is that the enormous power laid on to the lower notes of the organ enables the test of audibility to be made under most favourable circumstances, and that under these circumstances the limit of audible sounds can be carried down to a point close to the 32-foot C, or to a frequency of about 17.

Determination of frequency.

The determination of the frequency or vibration number of particular notes was first effected by calculations depending on the mechanical theory of strings. Subsequently the method of beats was employed, and the first reliable determinations appear to have been made by this method, which was developed by Scheibler. The usual process consists of providing a series of notes each of which makes four beats with its next neighbour, whence every such pair has vibration numbers differing by four. The series extends over an octave, whence the total difference of frequency between the extreme notes which form the octave is known. And this number is equal to the frequency of the lower note of the octave. This method, however, is difficult of execution, and depends on a number of observations, each of which is liable to error.

The method described in most of the books depends on the employment of the "siren." This consists essentially of a circular plate, revolving on an axis through its centre at right angles to its plane. Series of holes are arranged in circles, and puffs of air are sent through the holes as they move over fixed holes. In this way a known number of impulses is produced at each revolution. The revolutions are counted by a wheel work. With the more perfect forms of this instrument fair determinations of frequency could be effected by bringing the note of the instrument into coincidence with that to be determined, and counting the impulses delivered during a certain time. But until quite recently there was great uncertainty as to the actual frequency of the notes in use. In particular, the forks sold some time ago as 512 for treble C were for the most part several vibrations higher. And the various forks sold as philharmonic have at different times represented a great variety of pitches. The pitch of treble C has in recent times varied between the limits 512 and 540, being almost exactly a semitone. A few of the principal pitches may be summarized as follows:—



=512—old theoretical pitch.
518—equal temperament equivalent of French diapason normale. A=435.
528—Society of Arts. Helmholtz's theoretical pitch.
540—Modern concert pitch.

There is a tendency in practice to keep the pitch rising. This appears to arise from the habit among musicians of considering flatness in the orchestra or in singing a more heinous offence than sharpness. Everybody tries, at all events, not to be flat. Wind instruments made to concert pitch force the pitch up at all public performances. A rise is easily made, but a fall only with great difficulty. It will be seen that the pitch of the French diapason normale is the best part of a semitone below modern concert pitch, and the difficulty of getting it adopted is well known.

Forks stamped with the numbers of vibrations are now issued privately by some of the principal musical firms, and they appear to be fairly accurate. Probably they are copied from certain series of forks beating four per second which have been constructed according to Scheibler's process, so as to furnish the vibration numbers.

The most easy and convenient way of settling the frequency of tuning-forks, or rather of adjusting any vibrating body to a standard note, appears to be by means of a uniform rotation machine controlled by a clock so as to revolve exactly once per second. A disk is mounted on the machine, having say 135 radial slits spokewise. A light behind the disk then throws 135 flashes per second. If a tuning-fork or other vibrating body be placed in front of the disk and looked at against the illuminated background, it presents a pattern which will be stationary if the fork be 135 or 270 or 405 or 540, or any other multiple of 135. If the fork is sharp the pattern moves one way, if flat the other. In this way the vibration number of a vibrating body is referred directly to the clock, and the adjustment to the standard note is one easily made, and not requiring great delicacy of observation.

3. The loudness or intensity of notes undoubtedly increases with the magnitude of the displacements of which the vibrations consist, or rather perhaps with the magnitude of the changes of pressure which occur in the neighbourhood of the ear. It has been customary to speak of the energy of the vibration as affording a measure of intensity, and this is true from a mechanical point of view. But the subjective intensity or loudness is certainly not correctly measured by any of these quantities. Further, the same changes of pressure or the same mechanical intensity cause sounds which vary in loudness according to the pitch. Taking this last point first, it is easy to show that a given mechanical intensity produces a very much louder sound in the higher parts of the scale than in the lower. The simplest way of looking at this is to consider the work employed in exciting the pipes of an organ-stop. The upper pipes take only a small fraction of the wind, and consequently of the power, used by the lower ones, and yet the upper pipes appear quite as loud. It has been shown that with a particular stop the work consumed was proportional to the length of the pipe, and so inversely as the vibration number. Intensity

It has been maintained lately that the loudness of sound is measured by the amplitude of the motion, or by the changes of pressure, rather than by the mechanical intensity. The experiments on which this view is based consist of dropping weights from different heights. A weight m from a height h gives a certain loudness. Now let the weight be doubled, the question is whether the loudness remains the same when the height is halved, or when it is divided by $\sqrt{2}$. The experiments appear to prove that the latter is the case. The estimation of the loudness is difficult on account of the apparent change of timbre, but the experiments are carefully arranged and discussed, and appear to establish a *prima facie* case.[1] The experiments are based upon Fechner's law, and appear to afford proof of its applicability. Fechner's law may be stated thus:—equal differences of sensation are produced by changes which are equal fractions of the whole excitation. Thus we may take the change in the mechanical excitation to consist in doubling it; then every time that it is doubled a change will be made in the sensation which is in all cases equally recognizable. The general probability of the truth of this will be seen by enumerating ten different magnitudes under which sounds may be classified; these represent fairly equal differences of sensation:—

[1] *Vorr. Zeitschrift für Biologie*, 1879, p. 297.

Loud.					Not loud.				
1	2	3	4	5	6	7	8	9	10
fff	*ff*	*f*	*mf*	*mp*	*p*	*pp*	*ppp*		

Magnitude 1 serves for sounds louder than those used in music, 10 for sounds softer than those used in music,—microscopic sounds, so to speak. It seems reasonable, without going into detail, to assume that the mechanical ratio of any two consecutive magnitudes is the same. The general expression of this law is, The measure of sensation is the logarithm of the mechanical excitation. It appears probable that the ratio of energy corresponding to one of the above differences of magnitude is somewhere about 2 or 3. The corresponding ratio depending on amplitude or compression would be from 1·4 to 1·7, but these quantities are not known with any accuracy.

Quality corresponds to form of vibration.

4. The pitch depending on the period or frequency and the loudness on the amplitude or magnitude of the changes, there remains on the one hand the quality of tone, and on the other the form of the vibration or the manner in which the motion takes place between the prescribed limits. These may be expected to correspond with each other, and in fact they do so. The peculiarities of form of vibration are most easily discussed in the case of a musical string whose vibrations are started or maintained in a given manner. The smoothest and purest quality of tone that can be produced is known as a simple tone. When a string produces a simple tone its motion is such that its shape at any moment is that of a curve of sines, and that every point of the string executes oscillations according to the pendulum law.

Simple tones are also produced by any vibrating surface which moves according to the pendulum law. The method for producing simple tones given by Helmholtz, and commonly employed, is to use tuning-forks as the sources of sound, and present their extreme faces to the opening of a resonator or air-chamber arranged so as to vibrate to the same note as the fork. Resonators may be conveniently made from wide-mouthed bottles with flat corks having holes bored in them. The dimensions are usually found by trial, though data exist for their calculation. Simple tones have also been produced by fitting a sort of organ-pipe mouthpiece into the corks of such bottles. The mouths require to be cut up much higher than usual; the notes produced are of an exceedingly full and pure character. Such bottle-notes can be blown from an organ-bellows, and being easily manipulated are very suitable for experiments on the properties of simple tones.

The law of Ohm states that the simple tone or pendulum vibration is that to which the sensation of pitch is attached in its simplest form. If the motion which constitutes the vibration of a note be of any other type, it is capable of being analysed by the ear into a series of simple tones according to what is called Fourier's Theorem. This is most simply described in connexion with stretched strings, assuming that the notes which are exhibited in the form of the string pass over into the air through the sound-board without essential alteration of quality, which appears to be true in a general way. Fourier's Theorem, as applied to a string, states that the motion of the string is equivalent to the sum of the motions which would result if there were a curve of sines of the whole length, two curves of sines each of half the length, three each of one-third the length, and so on,—the amplitudes being determined when the total motion to be represented is given. This equivalence is true mechanically; the law of Ohm says that it is also true for the ear. Hence a great presumption that the ear acts by a receptive mechanism obeying the laws of mechanics.

The notes formed by the division of a string into two, three, or more parts are commonly called *harmonics*. They are also called *overtones*; but this word includes such cases as those of bars, &c., where the notes produced by these divisions are not harmonious with the fundamental. Harmonics play an important part in the theory of consonant combinations, but the theory of consonance cannot be rested entirely upon the properties of harmonics.

Consonance and Dissonance.

It was already known in ancient times that lengths of the same stretched string having the ratio of any two small whole numbers form consonant intervals, or perhaps we may more correctly say smooth combinations, since the interval of a fourth (3 : 4) is regarded as a dissonance in technical music, though it is a smooth combination. The question why smooth combinations are associated with small whole numbers is known as the Pythagorean question. The modern knowledge that the length of a given string is inversely as the vibration number refers the question more generally to vibration numbers rather than to lengths of string. This question has been answered by Helmholtz; we proceed to give a short account of his answer, with some slight modifications.

It has been long known that when two notes form an imperfect unison, or nearly form almost any smooth combination, flutterings or beats are heard. These have been already described in the case of imperfect unisons where two notes differ but little from each other in pitch. They exist also, in most cases, where two notes nearly, but not quite, form a smooth combination. According to Helmholtz, beats are the cause of the sensation of dissonance, and to seek further for this cause we must seek the cause of beats. We may note that this must be taken with some limitation, since the fourth is regarded as a dissonance, though it presents no beats. In the case of imperfect unisons there is no difficulty. Such beats have been long explained as arising out of the alternate coincidences and oppositions of the motions or pressures arising from the two sets of vibrations.

In other cases, however, this explanation is not applicable. Explanations similar in principle have been given by Smith, an English writer of the last century; but these only amount to reckoning the recurrence of certain configurations arising from the superposition of the two sets of motions. No hypothesis is made as to the actual nature of the receptive mechanism of the ear, and no attempt is made to determine of what sounds the beats consist, nor how such sounds arise. We have already seen that the ear receives separately notes which are more than one or two semitones apart. They appear to be received on different parts of the aural mechanism. The production of the beats in the case of imperfect fifths, octaves, &c., where the impulses fall on different parts of the receptive mechanism, appears therefore to be due to secondary causes rather than to the direct superposition of the impulses.

Beats of Harmonics.—This class of beats arises from the fact that in compound notes containing harmonics a pair of notes representing two small whole numbers gives rise to the coincidence of a pair of harmonics forming a unison, and, if the interval be mistuned, the harmonics form an imperfect unison. Beats of this description are easily identified by the pitch of the harmonics. The imperfect unison gives rise to alternations of sound and silence, or to variations of intensity, of a note having the pitch in question. With practice these variations can be heard with the unaided ear. But the employment of resonators, tuned to the pitch in question and connected with the ear, causes the beat to be heard with great intensity.

Beats of Combination Tones.—When two notes are

sounded loudly at the same time they give rise to the appearance of certain other notes within the ear, which are called combination tones. Call the vibration numbers of the two notes p and q. Then the first combination tone (Tartini tone, difference tone) has the frequency $p-q$. Other combination tones are also formed, whose frequencies are of the forms $p-2q$, $p-3q$, and so on. Each of these has its region of greatest intensity when its frequency is smallest consistently with its forming an audible sound. Thus the first difference tone $(p-q)$ is most powerful when p and q differ only by one or more semitones, though the note is still recognizable by the beats it produces when p and q are a fifth or an octave apart. The beats of mistuned consonant intervals other than the beats of harmonics are produced by the formation of imperfect unisons between combination tones and primaries, or among the combination tones themselves.

Intervals of the form $h:1$.—These comprise the intervals formed between fundamental and harmonics. The beats of mistuned consonances of the form $h:1$, other than the beats of harmonics, consist of variations of intensity of the lower note of the pair. This rule has been established experimentally by the employment of the pure notes furnished by bottles blown from an organ-bellows.

Octave. Let the notes be $100:201$. $p-q=101$, which with 100 gives one beat per second.

Twelfth. Let the notes be $100:301$. $p-2q=101$, which with 100 gives one beat per second.

Double octave. Let the notes be $100:401$. $p-3q=101$. One beat per second as before, and so on.

These explanations satisfy the observation that the beats are on the lower notes of the combinations.

Other Consonant Intervals.—The chief remaining consonance which furnishes beats is the fifth. There is no doubt that the beats of the fifth, other than the beats of harmonics, are chiefly on the octave below the lower note. Hence the following explanation:—

Fifth. Let the notes be $200:301$,

$$\begin{aligned} p-q &= 101 \\ 2q-p &= \underline{\ 99} \end{aligned}$$

2 beats per second, an octave below the lower note of the pair.

Triad with Mistuned Third.—If a fifth be tuned perfect and a third inserted, the note two octaves below the lowest note of the triad can generally be heard distinctly. If the third be mistuned, beats are heard on that note.

Let the notes be 400, 501, 600,

$$\begin{aligned} 501-400 &= 101 \\ 600-501 &= \underline{\ 99} \end{aligned}$$

2 beats per second, two octaves below the lowest note of the triad.

There can be little doubt that the definition of consonances as intervals which can be tuned free from beats lies at the basis of almost all music. There can also be little doubt that the power of the perception or memory of absolute pitch, though sparely distributed, must ensure to those musicians who have it influence on the progress of the art. With these persons the influence of consonance or smoothness is generally subordinate to the recognition of the pitch of the notes used. Between these two elements scales of different kinds have been evolved in different parts of the world. These scales have almost invariably a basis of consonances, generally fifths. But when once developed the melodic effects almost invariably supersede the reference to the consonances in the ears of expert persons. The scales of different countries and systems, embodied in melodies, sound atrocious to those accustomed to other scales, quite independently of the consonant relations on which they are all founded in common.

The subject of Temperament deals with the general theory of the construction of scales from slightly mistuned consonances. (R. H. M. B.)

MUSICAL-BOX, an instrument for producing by mechanical means tunes or pieces of music. The modern musical-box is an elaboration of the elegant toy musical snuff-box in vogue during the 18th century. The notes or musical sounds are produced by the vibration of steel teeth, or springs cut in a comb or flat plate of steel. The teeth are graduated in length from end to end of the comb or plate, the longer teeth giving the deeper notes; and, where necessary, by filing or loading with lead the individual teeth are accurately attuned. Each tone and semitone in the scale is represented by three or four separate teeth in the comb, to permit of successive repetitions of the same note when required by the music. The teeth are acted upon and musical vibrations produced by the revolution of a brass cylinder studded with projecting pins, which, as they move round, raise and release the proper teeth at due intervals according to the nature of the music. An entire revolution of the cylinder completes the performance of the special pieces of music for which the apparatus is set, but upon the same cylinder there may be inserted pins for performing as many as thirty-six separate airs. This is accomplished by making both the points of the teeth or springs and the projecting pins which touch them very fine, so that a very small change in the position of the cylinder is sufficient to bring an entirely distinct set of pins in contact with the note teeth. In the more elaborate musical-boxes the cylinders are removable, and may be replaced by others containing distinct sets of music. In these also there are combinations of bell, drum, cymbal, and triangle effects, &c. The revolving motion of the cylinder is effected by a spring and clock-work, and the rate of revolution is regulated by a fly regulator. The head-quarters of the musical-box trade is Geneva, where the manufacture gives employment to upwards of a thousand persons.

The musical-box is a type of numerous instruments for producing musical effects by mechanical means, in all of which a revolving cylinder or barrel studded with pins is the governing feature. The principle of the barrel operating by percussion or by wind on reeds, pipes, or strings governs earillons or music bells, barrel organs, mechanical flutes, celestial voices, harmoniphones, and the sometimes huge and complex orchestrions in which a combination of all orchestral effects is attempted. A principle of more recent introduction than the studded cylinder consists of sheets of perforated paper or card, somewhat similar to the Jacquard apparatus for weaving. The perforations correspond in position and length to the pitch and duration of the note they represent, and as the web or long sheet of paper passes over the instrument, the perforated holes are brought in proper position and sequence under the influence of the suction or pressure of air from a bellows, and thereby the notes are either directly acted on, as in the case of reed instruments, or the opening and closing of valves set in motion levers or liberate springs which govern special notes. The United States are the original home of the instruments controlled by perforated paper known as orguinettes, organinas, melodeons, &c.

MUSK, a substance of powerful and most enduring odour, is a secretion of the male MUSK DEER (*q.v.*). Three kinds of musk are distinguished in commerce, the most important and valuable being the Chinese or Tong-king musk, imported principally from Shanghai. It is put up in small tin-lined silk-covered caddies, each containing from two to three dozen pods. These are generally adulterated to an enormous extent with dried blood, fragments of leather, leaden pellets, peas, &c., so that often

little more than the smell of the original tenant of the pod remains. The Chinese pods may vary in value according to quality and genuineness from 14s. to 40s. per oz. Musk collected from the western Himalayas is exported from India to the extent of from 3000 to 5000 oz. annually. It is much less prized than genuine Tong-king musk. The third variety, known as Kabardine or Siberian musk, is imported from Central Asia by way of Russia. It is in large pods, said to be yielded by a distinct species of deer, and is very inferior in point of odour.

Good musk is of a dark purplish colour, dry, smooth, and unctuous to the touch and bitter in taste. It dissolves in boiling water to the extent of about one-half, alcohol takes up one-third of the substance, and ether and chloroform dissolve still less. A grain of musk will distinctly scent millions of cubic feet of air without any appreciable loss of weight, and its scent is not only more penetrating but more persistent than that of any other known substance. Its chemical constitution has not been specially investigated; but in addition to its odoriferous principle it contains ammonia, cholestrin, fatty matter, a bitter resinous substance and other animal principles. As a material in perfumery it is of the first importance, its powerful and enduring odour giving strength and permanency to the vegetable essences, so that it is a principal ingredient in nearly all compounded perfumes. Musk, or some substance possessed of the musk odour, is also contained in glands in the jaw of alligators and crocodiles, whence it has been extracted for use in perfumery in India and Egypt. The musk-ox and the musk-rat (Indian and European) are, as their names indicate, remarkable for a musk odour (see below). In the vegetable kingdom also a musky smell pervades the seeds of *Abelmoschus moschatus*, the entire plant *Mimulus moschatus*, and the sumbul root (*Euryangium Sumbul*).

MUSK-DEER, an animal belonging to the genus *Moschus*, of the section *Pecora*, a division of the *Artiodactyle Ungulates* (see MAMMALIA, vol. xv. p. 430), and allied to the Deer (*Cervidæ*). In many respects it differs from the typical members of that group and stands by itself as an isolated zoological form, retaining characters belonging to the older and more generalized types of ruminants before they were distinctly separated into the horned and the antlered sections now dominant upon the earth. One of these characters is that both sexes are entirely devoid of any sort of frontal appendage. In this, however, it agrees with one genus of true deer (*Hydropotes*); and, as in that animal, the upper canine teeth of the males are remarkably developed, long, slender, sharp-pointed, and gently curved, projecting downwards out of the mouth with the ends turned somewhat backwards. Among the anatomical peculiarities in which it differs from all true deer is the presence of a gall-bladder.

Although, owing to variations of colour presented by different individuals in different localities and seasons, several nominal species have been described, zoologists are now generally agreed that there is but one, the *Moschus moschiferus* of Linnæus. In size it is rather less than the European roe-deer, being about 20 inches high at the shoulder. Its limbs, especially the hinder ones, are long. The feet are remarkable for the great development of the lateral pair of hoofs, and for the freedom of motion they all present, so that they appear to have the power of grasping projecting rocky points,—a power which must be of great assistance to the animal in steadying it in its agile bounds among the crags of its native haunts. The ears are large, and the tail quite rudimentary. The hair covering the body is long, coarse, and of a peculiarly brittle and pith-like character, breaking with the application of an extremely slight force; it is generally of a greyish-brown colour, sometimes inclined to yellowish red, and often variegated with lighter patches. The Musk-deer has a wide distribution over the highlands of central and eastern Asia, including the greater part of southern Siberia, and extends to Kashmir on the south-west and Cochin-China on the south-east, always, however, at great elevations,—being rarely found in summer below 8000 feet above the sea-level, and ranging as high as the limits of the thickets of birch, rhododendron, and juniper, among which it mostly conceals itself in the day-time. It is a hardy, solitary, and retiring animal, chiefly nocturnal in its habits, and almost always found alone, rarely in pairs and never in herds. It is exceedingly active and surefooted, having perhaps no equal in traversing rocks and precipitous ground; and it feeds on moss, grass, and leaves of the plants which grow on the mountains among which it makes its home.

Musk-deer.

Most of the animals of the group to which the Musk-deer belongs, in fact the large majority of mammals, have some portion of the cutaneous surface peculiarly modified and provided with glands secreting some odorous and oleaginous substance specially characteristic of the species. This, correlated with the extraordinary development of the olfactory organs, appears to offer the principal means by which animals in a state of nature become aware of the presence of other individuals of their own species, or of those inimical to them, even at very great distances, and hence it is of extreme importance both to the wellbeing of the individual and to the continuance of the race. The situation of this specially modified portion of skin is extremely various, sometimes between the toes, as in sheep, sometimes on the face in front of the eyes, as in many deer and antelopes. Sometimes it is in the form of a simple depression or shallow recess, often very deeply involuted, and in its most complete state of development it forms a distinct pouch or sac with a narrow tubular orifice. In this sac a considerable quantity of the secretion can accumulate until discharged by the action of a compressor muscle which surrounds it. This is the form taken by the special gland of the Musk-deer, which has made the animal so well known, and which has proved the cause of an unremitting persecution to its possessor. It is found in the male only, and is a sac about the size of a small orange, situated beneath the skin of the abdomen, the orifice being immediately in front of the preputial aperture. The secretion with which the sac is filled is of dark-brown or chocolate colour, and when fresh described as being of the consistence of "moist gingerbread," but becoming dry, and granular after keeping. It has a peculiar and very powerful scent, which when properly diluted and treated forms the basis of many of our most admired perfumes. When the animal is killed the whole gland or "pod" is cut out and dried, and in this form reaches the market of the Western world, chiefly through China.

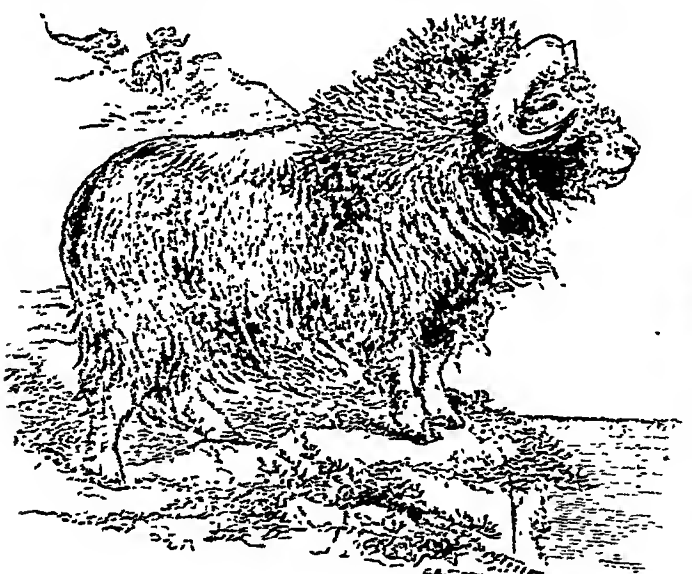
For further details on the anatomy and zoology of *Moschus* see Pallas, *Spicilegia Zoologica*, xiii. (1779); A. Milne-Edwards, "Recherches Anatomiques, Zoologiques, et Palæontologiques sur la Famille des Chevrotains," in *Annales des Sciences Naturelles*, 5th ser., zool., ii. (1865); Brandt and Ratzeburg, *Medicinische Zoologie*, i. pp. 41-51 (1839); W. H. Flower, *Proc. Zool. Soc. London*, 1875, pp. 159-190; A. H. Garrod, *ibid.*, 1877, pp. 287-292.

MUSKEGON, a city of the United States, the county seat of Muskegon county, Michigan, at the upper end of Muskegon Lake, a fine sheet of water formed by the Muskegon river before it falls into Lake Michigan. The staple trade is in lumber, which is floated down the river, worked up by its saw-mills and planing-mills, and exported by boat and rail. The cut of lumber in the season of 1882 was 650,000,000 feet. There are also car, engine, and boiler works, and various manufactories of wooden ware. The population increased from 6002 in 1870 to 11,262 in 1880. Settled in 1836, and laid out in 1853, Muskegon was incorporated as a village in 1861 and as a city in 1870.

MUSKELUNGE. See PIKE.

MUSK-OX. The animal commonly known by this name, though approaching in size the smaller varieties of oxen, is in structure and habits closely allied to the sheep, its affinities being well expressed by the generic name *Ovibos* bestowed upon it by De Blainville. The specific name *Moschatus*, as also the common English appellatives "musk-ox," "musk-buffalo," or "musk-sheep" applied to it by various authors, refer to the musky odour which the animal exhales. This does not appear to be due to the secretion of a special gland, as in the case of the Musk-deer; but it must be observed that, except as regards the osteology, very little is known of the anatomy of this species.

The *Ovibos moschatus* about equals in size the small



Musk-ox.

Welsh and Scotch cattle. The head is large and broad. The horns in the old males have extremely broad bases, meeting in the median line, and covering the brow and whole crown of the head. They are directed at first downwards by the side of the face and then turn upwards and forwards, ending in the same plane as the eye. Their basal halves are of a dull white colour, oval in section and coarsely fibrous; their middle part smooth, shining, and round; their tips black. In the females and young males the horns are smaller, and their bases are separated from each other by a space in the middle of the forehead. The ears are small, erect, and pointed, and nearly concealed in the hair. The space between the nostrils and the upper lip is covered with short close hair, as in sheep and goats, without any trace of the bare "muffle" of oxen. The greater part of the animal is covered with long brown hair, thick, matted, and curly on the shoulders, so as to give the appearance of a hump, but elsewhere straight and hanging down,—that of the sides, back, and haunches reaching as far as the middle of the legs and entirely concealing the very short tail. There is also a thick woolly under-fur, shed in the summer. The hair on the lower jaw, throat, and chest is long and straight, and hangs down like a beard or dewlap, though there is no loose fold of skin in this situation as in oxen. The limbs are stout and short, terminating in unsymmetrical hoofs, the external being rounded, the internal pointed, and the sole partially covered with hair.

The Musk-ox is at the present day confined to the most northern parts of North America, where it ranges over the rocky barren grounds between the 60th parallel and the shores of the Arctic Sea. Its southern range is gradually contracting, and it appears that it is no longer met with west of the Mackenzie river, though formerly abundant as far as Eschscholtz Bay. Northwards and eastwards it extends through the Parry Islands and Grinnell Land to north Greenland, reaching on the west coast as far south as Melville Bay; and it was also met with in abundance by the German polar expedition of 1869-1870 at Sabine Island on the east coast. No trace of it has been found in Spitzbergen or Franz Joseph Land. As proved by the discovery of fossil remains, it ranged during the Pleistocene period over northern Siberia and the plains of Germany and France, its bones occurring very generally in river deposits along with those of the reindeer, mammoth, and woolly rhinoceros. It has also been found in ordinary Pleistocene gravels in several parts of England, as Maidenhead, Bromley, Freshfield near Bath, Barnwood near Gloucester, and also in the lower brick earth of the Thames valley at Crayford, Kent.

It is gregarious in habit, assembling in herds of twenty or thirty head, or, according to Hearne, sometimes eighty or a hundred, in which there are seldom more than two or three full-grown males. They run with considerable speed, notwithstanding the shortness of their legs. Major H. W. Feilden, naturalist to the Arctic Expedition of 1875, says: "No person watching this animal in a state of nature could fail to see how essentially ovine are its actions. When alarmed they gather together like a flock of sheep herded by a collie dog, and the way in which they pack closely together and follow blindly the vacillating leadership of the old ram is unquestionably sheep-like. When thoroughly frightened they take to the hills, ascending precipitous slopes and scaling rocks with great agility." They feed chiefly on grass, but also on moss, lichens, and tender shoots of the willow and pine. The female brings forth one young one in the end of May or beginning of June after a gestation of nine months. According to Sir J. Richardson, "when this animal is fat its flesh is well tasted, and resembles that of the caribou, but has a coarser grain. The flesh of the bulls is highly flavoured, and both bulls and cows when lean smell strongly of musk, their flesh at the same time being very dark and tough, and certainly far inferior to that of any other ruminating animal existing in North America." The carcase of a Musk-ox weighs, exclusive of fat, above 3 cwt. On this subject Major Feilden says: "The cause of the disagreeable odour which frequently taints the flesh of these animals has received no elucidation from my observations. It does not appear to be confined to either sex, or to any particular season of the year; for a young unweaned animal, killed at its mother's side and transferred within an hour to the stew-pans, was as rank and objectionable as any. The flesh of some of these animals of which I have partaken was dark, tender, and as well flavoured as that of four-year old Southdown mutton" (*Zoologist*, September 1877).

See Richardson, *Fauna Boreali-Americana* (1829), and *Zoology of H.M.S. Herald* (1852); W. Boyd Dawkins, "*Ovibos moschatus*," in *British Pleistocene Mammalia*, part v.; *Memoirs of the Palæontographical Society* (1872).

MUSK-RAT. A name commonly applied to an animal also called MUSQUASH (*Fiber zibethicus*), of the sub-family *Arvicolinæ*, family *Muridæ*.[1] It is related in structure and habits to the English water-vole, but is of larger size, the head and body being about 12 inches in length and the tail but little less. It is rather a heavily-built animal, with a broad head, no distinct neck, and short limbs; the eyes are small, and the ears project very little beyond the fur. The fore-limbs have four toes and a rudimentary thumb, all with claws; the hind limbs are larger, with five distinct toes, united by short webs at their bases. The tail is laterally compressed, nearly naked, and scaly. The hair much resembles that of a beaver, but is shorter; it

[1] See MAMMALIA, vol. xv. p. 419, where also an illustration (fig. 94, p. 418) of its skull and dentition is given.

consists of a thick soft under-fur, interspersed with longer stiff, glistening hairs, which overlie and conceal the former, on the upper surface and sides of the body. The general colour is dark umber-brown, almost black on the back and grey below. The tail and naked parts of the feet are black. The musky odour from which it derives its name is due to the secretion of a large gland situated in the inguinal region, and present in both sexes.

The Musk-rat is the only species of its genus and is peculiar to America, being extensively distributed in suitable localities in the northern part of the continent, extend-

Musk-rat.

ing from the Atlantic to the Pacific, and from the Rio Grande to the barren grounds bordering the Arctic Seas. It is aquatic in its habits, living on the shores of lakes and rivers, swimming and diving with great facility, feeding on the roots, stems, and leaves of water-plants, or on fruits and vegetables which grow near the margin of the streams it inhabits. Musk-rats are most active at night, spending the greater part of the day concealed in their burrows dug out of the bank, consisting of a chamber with numerous passages, all of which open under the surface of the water. For winter quarters they build more elaborate houses of conical or dome-like form, composed of sedges, grasses, and similar materials plastered together with mud. As their fur is an important article of commerce, large numbers are annually killed, being either trapped or speared at the mouths of their holes.

The name Musk-rat is applied in India to a large species of Shrew (*Sorex cærulescens or indicus*) which frequents houses at night, hunting round rooms for cockroaches and other insects, occasionally uttering a sharp shrill cry. The strong musky odour of the animal arises from large glands beneath the skin of the side of the body, a short distance behind the fore-limbs. This odour is so powerful and penetrating that it is popularly believed in India that if the animal runs over a corked bottle of wine or beer it will infect the fluid within. Jerdon says that certainly many bottles are met with quite undrinkable from the peculiar musky odour of their contents, but, rejecting the possibility of its passing through the glass, he attributes it to the corks having been infected previously to bottling, stating in corroboration of this view that he has never found the odour in liquors bottled in England.

MUSLIN, a term embracing the thin delicate woven cotton fabrics, the lightest and most airy of all textures. The word is derived from Mosul; the original home of muslin-weaving is the East Indies, where even yet wonderful fabrics for airy lightness and delicacy continue to be woven with the aid of only the most rude and primitive appliances. The most delicate muslins are made at Dacca, where webs have been woven of yarn calculated to be equal to 380^{s} (that is, 380 hanks, each 840 yards in length, weigh 1 lb). Such a web measuring 10 yards 1 foot in length by 3 feet in breadth, and having 104 threads of warp and 100 of weft per inch, was found to weigh not more than 1565 grains. Figured, embroidered, colour-woven, and printed muslins are made at various places, principally in Madras province, and gold and silver printed muslins are made at Jeypore and Hyderabad in India. The making of muslin in Europe was first attempted at Glasgow by Robert Monteith about the year 1780, but he had to procure Indian bird-nest yarn for his web. The improvements in machinery effected about that time, however, soon enabled spinners to produce yarn of high counts, and thereafter the muslin trade took firm hold in the west of Scotland. In recent times the perfection of combing machinery, &c., has enabled spinners to supply yarn of much greater tenuity than has ever been spun in India, and indeed vastly finer than is of any use for weaving purposes. A few yards of muslin have been woven with 700^{s} cotton, but it is of use only to indicate the limit up to which it is possible to weave yarn. Fine muslin or tarlatan has been woven of 440^{s} yarn by M. Thivel Michon of Tarare in France, but to the eye and touch it is less fine and delicate than Dacca "mulmul khas," owing possibly to dressing with starch, and to the less degree of condensation in machine-spinning as compared with hand-spinning. The varieties of European muslins and their applications are numerous. Among plain muslins are included books, mulls (from "mulmul"), jaconets, tarlatans, Bishop and Victoria lawns, nainsooks, &c., chiefly distinguished by variety of finish, dressing, folding, &c. For window-curtains, hangings, &c., there are manufactured harness and book muslins, lenos, sprigs, spots, and lappets; and for ladies' dresses plain, striped, and figured grenadines, and saccarillas, besides which dyed and printed muslins are largely used. Sewed muslin, which was formerly an important Scottish industry, also continues to be a branch of the trade.

MUSSCHENBROEK, PIETER VAN (1692-1761), natural philosopher, was born at Leyden in March 1692, and studied at the university of his native city. The teacher from whom he derived the most profit was the eminent mathematician Gravesande. A scientific partnership was formed in 1717 between the master and the pupil for the prosecution of natural philosophy according to the principles of Newton, and in opposition to those of Descartes; Gravesande concentrating his attention on the theoretical part of the study, while Musschenbroek conducted the experiments. The consequence was that the downfall of Cartesianism and the establishment of Newtonianism were very much accelerated in Holland. Graduating in 1715 with a dissertation, *De aeris præsentia in humoribus animalium*, Musschenbroek was appointed professor at Duisburg in 1719. In 1723 he was promoted to the chair of natural philosophy and mathematics at Utrecht. In 1731 he declined an invitation to Copenhagen, and was promoted in consequence to the chair of astronomy at Utrecht in 1732. The attempt of George II. of England in 1737 to attract him to the newly-established university of Göttingen was also unsuccessful. At length, however, the claims of his native city overcame his resolution to remain at Utrecht, and he took possession of the mathematical chair at Leyden in 1739, where, declining all offers from abroad, he continued till his death in September 1761.

His first important production was *Epitome elementorum physico-mathematicorum*, 12mo, Leyden, 1726,—a work which was afterwards gradually altered as it passed through several editions, and which appeared at length (posthumously, edited by Ludolf) in 1762, under the title of *Introductio ad philosophiam naturalem*. The *Physicæ experimentales et geometricæ dissertationes* (1729) threw new light on magnetism, capillary attraction, and the cohesion of bodies. A Latin edition with notes (1731) of the Italian work *Saggi di naturali esperienze fatte nell' Accademia del Cimento* contained amid many other curious investigations a description of a

new instrument, the pyrometer, which Musschenbroek had invented, and of several experiments which he had made on the expansion of bodies by heat. Musschenbroek is also the author of *Elementa physica*, 8vo, 1734 (English translation 1744 by Colson), and of papers in the *Mémoires* of the Paris and St Petersburg Academies, and in the London *Philosophical Transactions.*

MUSSEL, a term applied in England to two families of Lamellibranch Molluscs,—the marine *Mytilacea*, of which the Edible Mussel, *Mytilus edulis*, is the representative, and the fresh-water *Unionacea*, of which the River Mussel, *Unio pictorum*, and the Swan Mussel, *Anodon cygneus*, are the common British examples. It is not obvious why these fresh-water forms have been associated popularly with the *Mytilacea* under the name Mussel, unless it be on account of the frequently very dark colour of their shells. They are somewhat remote from the sea mussels in structure, and have not even a common economic importance.

The Sea Mussel (*Mytilus edulis*) belongs to the second order of the class *Lamellibranchia* (see vol. xvi. pp. 685 *sq.*), namely, the *Heteromya*, in which the anterior or pallial adductor is much smaller than the pedal or posterior adductor. It and the other *Mytilacea* are remarkable for the comparatively free condition of the gill-filaments, which, whilst adhering to one another to form gill-plates (vol. xvi. p. 689, fig. 133), are yet not fused to one another by concrescence. It is also remarkable for the small size of its foot and the large development of two glands in the foot—the byssus-forming and the byssus-cementing glands.

The byssus is a collection of horny threads by which the Sea Mussel (like many other Lamellibranch or Bivalve Molluscs) fixes itself to stones, rocks, or submerged wood, but is not a permanent means of attachment, since it can be discarded by the animal, which, after a certain amount of locomotion, again fixes itself by new secretion of byssus from the foot. Such movement is, however, very rare. *Mytilus* possesses no siphonal tube-like productions of the margin of the mantle-skirt, nor any notching of the same, representative of the siphons which are found in its fresh-water ally, the *Dreissena polymorpha.*

Mytilus edulis is an exceedingly abundant and widely distributed form. It occurs on both sides of the northern Atlantic and in the Mediterranean basin. It presents varieties of form and colour according to the depth of water and other circumstances of its habitat. Usually it is found on the British coast encrusting rocks exposed at low tides, or on the flat surfaces formed by sandbanks overlying clay, the latter kind of colonies being known locally as "scalps." Under these conditions it forms continuous masses of individuals closely packed together, sometimes extending over many acres of surface and numbering millions. The readiness with which the young *Mytilus* attaches itself to wicker-work is made the means of artificially cultivating and securing these molluscs for the market both in the bay of Kiel in North Germany and at the mouth of the Somme and other spots on the coast of France.

Natural scalps are subject to extreme vicissitudes: an area of many acres may be destroyed by a local change of current producing a deposit of sand or shingle over the scalp, or by exposure to frost at low tide in winter, or by accumulation of decomposing vegetable matter. The chief localities of natural scalps on the British coast are Morecambe Bay in Lancashire and the flat eastern shores, especially that of the Wash of Lincoln, and similar shallow bays. These scalps are in some cases in the hands of private owners, but the English Government has not granted sufficiently definite rights to such individuals to enable them to protect their property from marauders, and to justify them in undertaking artificial cultivation.

The Sea Mussel is scarcely inferior in commercial value to the oyster. In 1873 the value of mussels exported from Antwerp alone to Paris to be used as human food was £280,000. In Britain their chief consumption is in the deep-sea line fishery, where they are held to be the most killing of all baits. Twenty-eight boats engaged in haddock-fishing at Eyemouth used between October 1882 and May 1883 920 tons of mussels (about 47 million individuals), costing nearly £1800 to the fishermen, about one-half of which sum was expended on the carriage of the mussels. It is quite impossible to calculate the number of tons of mussels annually used in this way by British fishermen, but it amounts to some hundreds of thousands, and the supplying of the market would offer a lucrative investment for capital did the Government grant definite proprietary rights over the fore-shore and sea-bottom to those ready to enter upon such enterprise. Many thousand tons of mussels are wastefully employed as manure by the farmers on lands adjoining scalp-producing coast, as in Lancashire and Norfolk, three half-pence a bushel being the price quoted in such cases. It is a curious fact, illustrative of the ignorant procedure and arbitrary fashions of fisher-folk, that on the Atlantic seaboard of the United States the Sea Mussel, *Mytilus edulis*, though common, is not used as bait nor as food. Instead, the Soft Clam, *Mya arenaria*, a Lamellibranch not used by English or Norwegian fishermen, though abundant on their shores, is employed as bait by the fishermen to the extent of 1¼ million bushels per annum, valued at £120,000. At the mouth of the river Conway in North Wales the Sea Mussel is crushed in large quantities in order to extract pearls of an inferior quality which are occasionally found in these as in other Lamellibranch Molluscs (Gwyn Jeffreys).

Mytilus edulis is considered of fair size for eating when it is 2 inches in length, which size is attained in three years after the spat or young mussel has fixed itself. Under favourable circumstances it will grow much larger than this, specimens being recorded of 9 inches in length. It is very tolerant of fresh water, fattening best, as does the oyster, in water of density 1014 (the density of the water of the North Sea being 1026). Experiments made by removing mussels from salt water to brackish, and finally to quite fresh water show that it is even more tolerant of fresh water than the oyster; of thirty mussels so transferred all were alive after fifteen days. *Mytilus edulis* is occasionally poisonous, owing to conditions not satisfactorily determined.

The fresh-water Mussels, *Anodon cygneus*, *Unio pictorum*, and *Unio margaritiferus* belong to the order Isomya of Lamellibranch Molluscs, in which the anterior and posterior adductor muscles are equally developed. An account of the anatomy of *Anodon* is given in the article MOLLUSCA. *Unio* differs in no important point from *Anodon* in internal structure. The family *Unionacea*, to which these genera belong, is of world-wide distribution, and its species occur only in ponds and rivers. A vast number of species arranged in several genera and sub-genera have been distinguished, but in the British Islands the three species above named are the only claimants to the title of "fresh-water mussel."

Anodon cygneus, the Pond Mussel or Swan Mussel, appears to be entirely without economic importance. *Unio pictorum*, the common River Mussel (Thames), appears to owe its name to the fact that the shells were used at one time for holding water-colour paints as now shells of this species and of the Sea Mussel are used for holding gold and silver paint sold by artists' colourmen, but it has no other economic value. *Unio margaritiferus*, the Pearl Mussel, was at one time of considerable importance as a source of pearls, and the pearl mussel fishery is to this day carried on under peculiar state regulations in Sweden and Saxony, and other parts of the Continent. In Scotland and Ireland the pearl mussel fishery was also of importance, but has altogether dwindled into insignificance since the opening up of commercial intercourse with the East and with the islands of the Pacific Ocean, whence finer and more abundant pearls than those of *Unio margaritiferus* are derived.

In the last forty years of the last century pearls were exported from the Scotch fisheries to Paris to the value of £100,000; round pearls, the size of a pea, perfect in every respect, were worth £3 or £4. The Pearl Mussel is still used as bait in the Aberdeen cod fishery.

For an account of the anatomy of *Mytilus edulis* the reader is referred to the treatise by Sabatier on that subject (Paris, 1875). Its development from the egg has not been fully studied, but some very important facts as to the structure of the free-swimming young or spat are to be found in the memoir by Lacaze Duthiers, *Annales des Sciences Naturelles*, 1856. The essay by Mr Charles Harding on *Molluscs used for Food or Bait*, published by the committee of the London International Fisheries Exhibition, 1883, may be consulted as to the economic questions connected with the Sea Mussel. (E. R. L.)

MUSSELBURGH, a Scottish burgh of barony and regality, a municipal and parliamentary burgh in the parish of Inveresk and county of Midlothian, 5½ miles east of Edinburgh. The burgh, which stretches about a mile

along the south shore of the Firth of Forth, is intersected by the river Esk and embraces the village of Fisherrow. In the town is Pinkie House, an ancient baronial residence, formerly a seat of the abbot of Dunfermline, whose monastery held the lands and regality before the Reformation. About a mile to the south-east the battle of Pinkie, so disastrous to the Scottish arms, was fought in 1547. Musselburgh is a place of great antiquity; one of the two stone bridges over the Esk is said to represent an ancient Roman structure, and remains of Roman work have been found at Inveresk in the immediate vicinity. The town has an important factory for fishing-nets, a paper mill, breweries, and other manufactories, and there is a harbour, chiefly for fishermen, at Fisherrow. Loretto School here has its name from the old chapel of Loretto, founded in 1534 by Thomas Duthy, a hermit from Mount Sinai. The Musselburgh Links, east of the river, are much frequented by golfers, and upon the Links there is a good racecourse. The population of the burgh in 1881 was 7866.

MUSSET, ALFRED DE (1810-1857), poet, play-writer, and novelist, was born on the 11th December 1810 in a house in the middle of old Paris, near the Hôtel Cluny. His father, Victor de Musset, who in the course of his life held several ministerial posts of importance, traced his descent back as far as 1140. In Alfred's childhood there were various things which fostered his imaginative power. He and his brother Paul, who afterwards wrote a biography of Alfred, delighted in reading old romances together, and in assuming the characters of the heroes of these romances. But it was not until about 1826 that Musset gave any definite sign of the mental force which afterwards distinguished him. In the summer of 1827 he all but won a prix d'honneur by an essay on "The origin of our feelings," and in 1828, when Scribe, Mélesville, and the elder Brazier were in the habit of coming to Madame de Musset's house at Auteuil, where drawing-room plays and charades were constantly given, Musset, excited by this companionship, wrote his first poem, which, to judge from the extracts preserved, was neither better nor worse than much other work of clever boys who may or may not afterwards turn out to be possessed of genius. Shortly after his first attempt in verse he was taken by Paul Foucher to Victor Hugo's house, where he met such men as Alfred de Vigny, Mérimée, and Sainte-Beuve. It was under Hugo's influence, no doubt, that he composed a play. The scene was laid in Spain, and some lines, showing a marked advance upon his first effort, are preserved. In 1828, when the war between the classical and the romantic school of literature was growing daily more serious and exciting, Musset, who had published some verses in a country newspaper, boldly recited some of his work to Sainte-Beuve, who wrote of it to a friend, "There is amongst us a boy full of genius." At eighteen years old Musset produced a translation, with a few insertions of his own, of De Quincey's *Opium-Eater*. This was published by Mame, attracted no attention, and has been long out of print. His first original volume was published in 1829 under the name of *Contes d'Espagne et d'Italie*, had an immediate and striking success, provoked bitter opposition, and produced many unworthy imitations. In December 1830 he was just twenty years old, and was already conscious of that curious double existence within him so frequently symbolized in his plays,—in Octave and Célio for instance (in *Les Caprices de Marianne*), who also stand for the two camps, the men of matter and the men of feeling,—which he has elsewhere described as characteristic of his generation. At this date his piece the *Nuit Vénitienne* was produced by Harel, manager of the Odéon. The exact causes of its failure might now be far to seek; unlucky stage accidents had something to do with it, but there seems reason to believe that there was a strongly-organized opposition. However this may be, the result was disastrous to the French stage; for it put a complete damper on the one poet who, as he afterwards showed both in theoretical and in practical writings, had the fine insight which took in at a glance the merits and defects both of the classical and the romantic schools. Thus he was strong and keen to weld together the merits of both schools in a new method which, but for the fact that there has been no successor to grasp the wand which its originator wielded, might well be called the school of Musset. The serious effect produced upon Musset by the failure of his *Nuit Vénitienne* is curiously illustrative of his character. A man of greater strength and with equal belief in his own genius might have gone on appealing to the public until he compelled them to hear him. Musset gave up the attempt in disgust, and waited until the public were eager to hear him without any invitation on his part. In the case of his finest plays this did not happen until after his death; but long before that he was fully recognized as a poet of the first rank, and as an extraordinary master of character and language in prose-writing. In his complete disgust with the stage after the failure above referred to there was no doubt something of a not ignoble pride, but there was something also of weakness—of a kind of weakness out of which it must be said sprang some of his most exquisite work, some of the poems which could only have been written by a man who was face to face with difficulties which were old enough in the experience of mankind, though for the moment new and strange to him, and by which he felt himself to be overwhelmed.

In 1833 Musset published the volume called *Un Spectacle dans un Fauteuil*. One of the most striking pieces in this—*Namouna*—was written at the publisher's request to fill up some empty space; and this fact is noteworthy when taken in conjunction with the horror which Musset afterwards so often expressed of doing anything like writing "to order,"—of writing, indeed, in any way or at any moment except when the inspiration or the fancy happened to seize him. The success of the volume seemed to be small in comparison with that of his *Contes d'Espagne*, but it led indirectly to Musset's being engaged as a contributor to the *Revue des Deux Mondes*. In this he published, in April 1833, *André del Sarto*, and he followed this six weeks later with *Les Caprices de Marianne*. This play, which now ranks as one of the classical pieces in the repertory of the Théâtre Français, is a fine illustration of the method above referred to, a method of which Musset gave something like a definite explication five years later. This explication was also published in the *Revue des Deux Mondes*, and it set forth that the war between the classical and the romantic schools could never end in a definite victory for either school, nor was it desirable that it should so end. "It was time," Musset said, "for a third school which should unite the merits of each." And in *Les Caprices de Marianne* these merits are most curiously and happily combined. It so happens that, as the piece is generally given on the stage, with the omission of one change of scene, the classical unities are almost exactly preserved, while the whole play is impregnated with romanticism in the best sense of the word. It has perhaps more of the Shakespearean quality—the quality of artfully mingling the terrible, the grotesque, and the high comedy tones—which exists more or less in all Musset's longer and more serious plays than is found in any other of these. In Claudio, the husband, the terrible and the grotesque are strangely and powerfully allied; Tibia, his serving-man, is grotesque with a touch of grimness caught from his master; Octave and Célio represent the two elements which were always warring in Musset's own heart—one is the careless half-

cynical man of the world and the other the wholly tender romantic lover; Marianne is that type of the highest comedy to which events lend a touch of tragedy, while in Hermia, Célio's mother, is the very poetry of maternal love. The piece is called a comedy, and it owes this title to its extraordinary brilliance of dialogue, truth of characterization, and swiftness in action, under which there is ever latent a sense of impending fate. Many of the qualities indicated are found in others of Musset's dramatic works, and notably in *On ne badine pas avec l'Amour*, where the skill in insensibly preparing his hearers or readers through a succession of dazzling comedy scenes for the swift destruction of the end is very marked. But *Les Caprices de Marianne* is perhaps for this particular purpose of illustration the most compact and most typical of all. One other point in Musset's method may be noted in connexion with this play. Paul de Musset asked him where he had ever met a Marianne. He answered, "Everywhere and nowhere; she is not a woman, she is woman." The appearance of *Les Caprices de Marianne* in the *Revue* was followed by that of *Rolla*, a marked symptom of the "maladie du siècle." Then came the unfortunate journey which Musset made to Italy with George Sand. It is well known that the rupture of what was for a time a most passionate attachment had a disastrous effect upon Musset, and brought out the weakest side of his moral character. He was at first absolutely and completely struck down by the blow. But it was not so well known until Paul de Musset pointed it out that the passion expressed in the *Nuit de Décembre*, written about twelve months after the journey to Italy, referred not to George Sand but to another and quite a different woman. The story of the Italian journey and its results are told under the guise of fiction from two points of view in the two volumes called respectively *Elle et Lui* and *Lui et Elle*. During Musset's absence in Italy *Fantasio* was published in the *Revue*, and not long after his return *On ne badine pas avec l'Amour* appeared in the same way. In 1835 he produced *Lucie, La Nuit de Mai, La Quenouille de Barberine, Le Chandelier, La Loi sur la Presse, La Nuit de Décembre*, and *La Confession d'un Enfant du Siècle*. The last-named work, a prose work, is exceptionally interesting as exhibiting the poet's frame of mind at the time, and the approach to a revulsion from the Bonapartist ideas amid which he had been brought up in his childhood. To the supreme power of Napoleon he in this work attributed that moral sickness of the time which he described. "One man," he wrote, "absorbed the whole life of Europe; the rest of the human race struggled to fill their lungs with the air that he had breathed." When the emperor fell, "a ruined world was a resting-place for a generation weighted with care." The *Confession* is further important, apart from its high literary merit, as exhibiting in many passages the poet's tendency to shun or wildly protest against all that is disagreeable or difficult in human life—a tendency to which, however, much of his finest work was due. In 1836 appeared, amongst other things, *Il ne faut jurer de Rien*, a comedy which holds, and is likely long to hold, the stage of the Théâtre Français, and the beginning of the brilliant letters of Dupuis and Cotonet on romanticism. *Il ne faut jurer de Rien* is as typical of his comedy work as is *Les Caprices de Marianne* of the work in which a terrible fatality underlies the brilliant dialogue and light keen characterization. In 1839 were published the *Caprice* (which afterwards found its way to the Paris stage through, in the first instance, the accident of Madame Allan the actress hearing of it in a Russian translation) and some of the *Nouvelles*. In 1839 he began a romance called *Le Poëte Déchu*, of which the existing fragments are full of passion and insight. In 1840 he passed through a period of feeling that the public did not recognize his genius—as, indeed, they did not—and wrote a very short but very striking series of reflexions headed with the words "A trente Ans," which Paul de Musset published in his *Life*. In 1841 there came out in the *Revue de Paris* Musset's *Le Rhin Allemand*, an answer to Becker's poem which appeared in the *Revue des Deux Mondes*. This fine war-song made a great deal of noise, and brought to the poet quantities of challenges from German officers. Between this date and 1845 he wrote comparatively little. In the last-named year the charming "proverbe" *Il faut qu'une Porte soit ouverte ou fermée* appeared. In 1847 *Un Caprice* was produced at the Théâtre Français, and the employment in it of such a word as "rebonsoir" shocked some of the old guard of the old school. In 1848 *Il ne faut jurer de Rien* was played at the Théâtre Français, and the *Chandelier* at the Théâtre Historique. Between this date and 1851 *Bettine* was produced on the stage and *Carmosine* written; and between this time and the date of his death, from an affection of the heart, in May 1857, the poet produced no large work of importance.

Alfred de Musset now holds the rank which Sainte-Beuve first accorded, then denied, and then again accorded to him as a poet of the first rank. He had genius, though not genius of that strongest kind which its possessor can always keep in check. His own character worked both for and against his success as a writer. His very weakness and his own consciousness of it produced such beautiful work as, to take one instance, the *Nuit d'Octobre*, but it too often prevented him, from one cause or another, from producing any work at all. His *Nouvelles* are extraordinarily brilliant; his poems are charged with passion, fancy, and fine satiric power; in his plays he hit upon a method of his own, in which no one has dared or availed to follow him with any closeness. He was one of the first, most original, and in the end most successful of the first-rate writers included in the phrase "the 1830 period." The wildness of his life, though it cannot be denied, has probably been exaggerated; and it has lately been suggested by M. Arsène Houssaye that the symptoms of the heart disease which caused his death may sometimes have been mistaken for the symptoms of intoxication. His brother Paul de Musset has given in his *Biographie* a striking testimony to the finer side of his character. In the later years of his life Musset was elected, not without some difficulty, a member of the French Academy. Besides the works above referred to, the *Nouvelles et Contes* and the *Œuvres Posthumes*, in which there is much of interest concerning the great tragic actress Rachel, should be specially mentioned. Musset has had no successor in France either as a poet or as a dramatist. (W. H. P.)

MUSTARD. The varieties of mustard-seed of commerce are produced from several species of the Cruciferous genus *Brassica*. Of these the principal are the Black or Brown Mustard, *Brassica nigra* (*Sinapis nigra*, L.), the White Mustard, *Brassica alba*, and the Sarepta Mustard, *B. juncea*. The finest qualities of Black and White Mustard are cultivated in the eastern counties of England. The former is a plant requiring a rich soil and much care in its treatment, but its seeds, which are very minute, weighing not more than one-fiftieth of a grain, are the most valuable for commercial purposes. The peculiar pungency and odour to which mustard owes much of its value are due to an essential oil developed by the action of water on two peculiar chemical substances contained in the black seed. These bodies are a compound termed by its discoverers myronate of potassium, but since called sinigrin, $C_{10}H_{18}KNS_2O_{10}$, and an albuminoid body, myrosin. The latter substance in presence of water acts as a ferment on sinigrin, splitting it up into the essential oil of mustard, a potassium salt, and sugar. It is worthy of remark that this reaction does not take place in presence of boiling water, and therefore it is not proper to use very hot water in the preparation of mustard. Essential oil of mustard is in chemical constitution an iso-sulphocyanate of allyl C_4H_5NS. It is prepared artificially by a process, discovered by Zinzin, which consists in treating bromide of allyl with sulphocyanate of ammonium and distilling the resultant sulphocyanate of allyl. The seed of White Mustard contains in place of sinigrin a peculiar principle called sinalbin,

$C_{30}H_{44}N_2S_2O_{16}$, in several aspects analogous to sinigrin. In presence of water it is acted upon by myrosin, present also in White Mustard, splitting it up into sulphocyanate of acrinyl, sulphate of sinapine, and sugar. Sulphocyanate of acrinyl is a powerful rubefacient principle, whence White Mustard, although yielding no volatile oil, forms a valuable material for cataplasms. The seeds of *Brassica juncea* have the same constitution and properties as Black Mustard, as a substitute for which they are extensively cultivated in Russia. The mustard-seed imported from the East Indies is also largely composed of *B. juncea*.

Both as a table condiment and as a medicinal substance, mustard has been known from a very remote period. Under the name of *νᾶπυ* it was used by Hippocrates in medicine. The form in which table mustard is now sold in the United Kingdom dates from 1720, about which time Mrs Clements of Durham hit on the idea of grinding the seed in a mill and sifting the flour from the husk. The bright yellow farina thereby produced under the name of "Durham mustard" pleased the taste of George I., and rapidly attained wide popularity. As it is now prepared mustard consists essentially of a mixture of black and white farina in certain proportions. Several grades of pure mustard are made containing nothing but the farina of mustard-seed, the lower qualities having larger amounts of the white cheaper mustard; and corresponding grades of a mixed preparation of equal price, but containing certain proportions of wheaten or starch flour, are also prepared and sold as "mustard condiment." The mixture is free from the unmitigated bitterness and sharpness of flavour of pure mustard, and it keeps much better.

All varieties of mustard-seed contain from 25 to 35 per cent. of a bland inodorous yellow-coloured fixed oil, free from pungency and with little tendency to become rancid. It is extensively used in India for cooking and all ordinary purposes, and is one of the ordinary commercial oils of Western countries. The mustard papers commonly used as rubefacients and vesicants are made from mustard flour entirely deprived of its fixed oil.

MUTINY. This word, which primarily means a commotion and then an insurrection or sedition, is in English military law applied to a sedition in any forces belonging to Her Majesty's regular, reserve, or auxiliary forces, or navy. Such offences are dealt with by courts-martial, which up to the year 1879 derived their authority from the annual Mutiny Act (Act for punishing Mutiny and Desertion and for the better payment of the Army and their Quarters), the maintenance of a standing army in time of peace being illegal without the consent of parliament. For further details see Military Law and Court Martial.

MUTTRA, a district in the lieutenant-governorship of the North-Western Provinces, India, lying between 27° 14′ and 27° 58′ N. lat. and 77° 19′ and 78° 33′ E. long., is bounded on the N. by Alígarh and Gurgáon, on the E. by Alígarh, Máinpuri, and Etah, on the S. by Agra, and on the W. by Bhartpur state, with an area of 1453 square miles. The district consists of an irregular strip of territory lying on both sides of the Jumna. The general level is only broken at the south-western angle by low ranges of limestone hills. The eastern half consists for the most part of a rich upland plain, abundantly irrigated by wells, rivers, and canals, while the western portion, though rich in mythological association and antiquarian remains, is comparatively unfavoured by nature. The crops are scanty, and the larger forest trees are not found. For eight months of the year the Jumna shrinks to the dimensions of a mere rivulet, meandering through a waste of sand. During the rains, however, it swells to a mighty stream, a mile or more in breadth. Till recently nearly the whole of Muttra consisted of pasture and woodland, but new roads constructed as relief works in 1837-38 have thrown open many large tracts of country, and the task of reclamation has since proceeded rapidly.

The census of 1881 returned the population of Muttra at 671,690 (males 360,967, females 310,723), Hindus numbering 611,669 and Mohammedans 58,088. There were only 65 native Christians. The population of the three municipal towns in 1881 was as follows:—Muttra, 55,016; Brindaban, 21,467; and Kosi, 11,231. In 1881-82, 1048 square miles were returned as cultivated, 172 as cultivable, and 103 as uncultivable. *Joár* and cotton form the principal staples for the autumn (*kharíf*) harvest, while gram and barley are the chief grains grown for the spring (*rabí*) harvest. Sugar-cane, tobacco, indigo, and vegetables are all but unknown. The mass of the population is fairly well off, and the peasantry are described as being in better circumstances than those of neighbouring districts. Great extremes of temperature occur, the cold of winter being comparatively excessive, while hot winds blow from the west with great violence during April, May, and June. The average rainfall for the ten years ending 1869 was 23·6 inches.

The central portion of Muttra district forms one of the most sacred spots in Hindu mythology. A circuit of 84 *kos* around Gokul and Brindaban bears the name of the Braj-Mandal, and carries with it many associations of the earliest Aryan times. Here Krishna and his brother Balaráma fed their cattle upon the plain; and numerous relics of antiquity in the towns of Muttra, Gobardhán, Gokul, Mahában, and Brindaban still attest the sanctity with which this holy tract was invested. During the Buddhist period Muttra became a centre of the new faith. After the invasion of Mahmúd of Ghazni the city fell into insignificance till the reign of Akbar; and thenceforward its history merges in that of the Játs of Bhartpur, until it again acquired separate individuality under Suráj Mall in the middle of the last century. The Bhartpur chiefs took an active part in the disturbances consequent on the declining power of the Mughal emperors, sometimes on the imperial side, and at others with the Mahrattas. The whole of Muttra passed under British rule in 1804.

Muttra, chief town and administrative headquarters of the above district, is situated on the right bank of the Jumna, about 30 miles above Agra, in 27° 30′ N. lat. and 77° 43′ E. long., with a population (1881) of 55,016, viz., males 28,769, and females 26,247.

It is an ancient town, mentioned by Fa Hian as a centre of Buddhism about 400 A.D.; his successor Hiouen Thsang, about 650, states that it then contained twenty Buddhist monasteries and five Brahmanical temples. Muttra has suffered more from Mohammedan sack and plunder than most of the towns of northern India. It was sacked by Mahmúd of Ghazni in 1017-18; about 1500 Sultán Sikandar Lodi utterly destroyed all the Hindu shrines, temples, and images; and in 1636 Sháh Jahán appointed a governor expressly to "stamp out idolatry." In 1669-70 Aurangzeb visited the city and continued the work of destruction. Muttra was again captured and plundered by Ahmad Sháh with 25,000 Afghán cavalry in 1756. The town still forms a great centre of Hindu devotion, and large numbers of pilgrims flock annually to the festivals.

MUZAFFARGARH, a district in the lieutenant-governorship of the Punjab, India, lying between 29° 1′ and 30° 46′ N. lat. and 70° 33′ and 71° 49′ E. long., is bounded on the N. by Derá Ismáil Khán and Jhang districts, on the E. and S.E. by the Chenáb river, and on the W. by the Indus, with an area of 3136 square miles. It occupies the extreme southern apex of the Sind Ságar Doáb, the wedge-shaped tract between the Indus and the Five Rivers or Panjnad. The district stretches northward from their confluence in a narrow ridge of land, gradually widening for about 120 miles, until at its northern border it is 55 miles broad. In the northern half of the district is the wild *thal* or central desert of the Sind Ságar Doáb, an arid elevated tract with a width of 40 miles in the extreme north, which gradually contracts until it disappears about 10 miles south of Muzaffargarh town. Although apparently a tableland, it is really composed of separate sandhills, with intermediate valleys lying at a lower level than that of the Indus, and at times flooded. Scattered amid this waste of sand-heaps are a few good plots of land, which the industry of the Ját cultivators has appropriated. The border strips fringing the *thal* towards the rivers are also for the most part under cultivation. South of the *thal*, the country consists of rich and productive lands, out of the reach of excessive flooding and at the same time within

reach of easy irrigation. But in the extreme south the floods from the two rivers spread at times over the whole intervening tract. On abating they leave luxuriant pasturage; and, if the subsidence takes place sufficiently early, magnificent crops of wheat, pease, and other grain are raised in the cultivated portion. The towns stand on high sites or are protected by embankments; but the villages scattered over the lowlands are exposed to annual inundations, during which the people abandon their grass-built huts and take refuge on wooden platforms attached to each house. Throughout the cold weather large herds of camels, belonging chiefly to the Povindah merchants of Afghánistán, graze upon the sandy waste.

The census of 1881 returned the population at 338,605 (males, 184,510, females 154,095), viz., 292,476 Mohammedans, 43,297 Hindus, 2783 Sikhs, 33 Christians, and 44 "others." The district contains only one town with a population exceeding 5000—namely, Kot Adu or Parhar (5552). Muzaffargarh, the headquarters station, has only 3136 inhabitants. The area under cultivation in 1881 was returned at 397,529 acres, of which 279,103 were irrigated by government works, and 118,376 by private individuals. The areas under the different crops in 1881-82 were rice 35,589 acres, wheat 193,749. great millet 15,915, spiked millet 15,431, barley 11,450, pease 32,385, gram 7959, *masúr* 6382, and tobacco 655. Most of the land is cultivated by the proprietors themselves; and the rents, where they exist, are almost universally paid in kind. Trade is mainly in the hands of Povindah merchants. The district is unusually hot and dry, the average rainfall for the seven years ending 1872-73 being only 5·9 inches.

Muzaffargarh possesses hardly any distinct annals of its own, having always formed part of MÚLTÁN (*q.v.*).

MUZAFFARNAGAR or MOZUFFERNUGGER, a district in the lieutenant-governorship of the North-Western Provinces, India, lying between 29° 11′ and 29° 45′ N. lat. and 77° 3′ and 78° 10′ E. long., is bounded on the N. by Sahâranpur, on the E. by the Ganges, on the S. by Meerut, and on the W. by the Jumna, with an area of 1656 square miles. It lies near the northern extremity of the Doab or great alluvial plain between the Ganges and the Jumna, and shares to a large extent in the general monotony of that level region. A great portion of the area is sandy and unfertile, but under irrigation the soil is rapidly improving, and in many places the villages have succeeded in introducing a high state of cultivation.

The census of 1881 returned the population at 758,444 (males 409,436, females 349,008). The excessive proportion of males is doubtless due to the practice of female infanticide, which Government has done all in its power to suppress. In 1874 no less than ninety-four villages were still on the "proclaimed" list under the Infanticide Act. Hindus numbered 535,218, Mohammedans 213,842, Christians 54, and Buddhists 9330. The population of the four municipal towns in 1881 was as follows—Muzaffarnagar (the chief town and administrative headquarters), 15,080; Kairana, 18,374; Kándhla, 11,109; Shamlí, 7359. Out of a total area of 1,059,910 acres in 1881-82, 707,394 were returned as under cultivation. In the *rabi* harvest the chief crops are wheat, barley, millet, and pulse. The *kharif* or autumn crops include the above grains, together with sugar-cane, cotton, and indigo. Irrigation was afforded in 1881-82 by one or other of the great canals to 219,121 acres. The condition of the peasantry is comfortable, and the village communities are prosperous and intelligent. Most of the land is cultivated by husbandmen with rights of occupancy; the number of tenants-at-will is rapidly declining. Rents are more frequently paid in kind than in cash. Before the opening of the canals Muzaffarnagar was liable to famines caused by drought: but the danger from this has been minimized by the spread of irrigation. Its trade is confined to the raw materials it produces. The climate of the district is comparatively cool owing to its proximity to the hills; and the average rainfall is about 29 inches.

Hindu tradition represents Muzaffarnagar as having formed a portion of the Pandáva kingdom of the *Mahábhárata*; authentic history, however, dates from the time of the Moslem conquests in the 13th century, from which time it remained a dependency of the various Mohammedan dynasties which ruled at Delhi until the political downfall of the Mughal empire in the middle of the last century. In 1788 the district fell into the hands of the Mahrattas. After the fall of Alígarh, the whole Doáb as far north as the Siwálik hills passed into the hands of the British without a blow, and Muzaffarnagar became part of Sahâranpur. It was created a separate jurisdiction in 1824.

MUZAFFARNAGAR, chief town and administrative headquarters of the above district, is situated on the military road from Meerut to Landaur in 29° 28′ N. lat. and 77° 44′ E. long. The population in 1881 was 15,080, of whom 8814 were males and 6266 females. It is a closely-built town, crowded with small lanes, and was founded in 1633. It is now a station on the Sind, Punjáb, and Delhi Railway, and has a considerable trade in agricultural produce.

MUZAFFARPUR or MOZUFFERPORE, a district in the lieutenant-governorship of Bengal, India, lying between 25° 30′ and 26° 51′ N. lat. and 84° 55′ and 85° 58′ E. long., is bounded on the N. by Nepál, E. by Darbhangah, on the S. by Patná, and W. by Sáran and Champáran districts, with an area of 3004 square miles. It was formed in January 1875 out of the great district of Tirhut, which up to that time was the largest and most populous district of lower Bengal. Of its six subdivisions, the three eastern were in January 1875 formed into the new district of Darbhangah, and the three western—Muzaffarpur, Hájipur, and Tájpur—into the district of Muzaffarpur.

The census of 1881 returned the inhabitants at 2,582,060 (males 1,265,731, females 1,316,329), viz., Hindus 2,265,380, Mohammedans 316,308, Europeans 140, mixed races 43, native Christians 179. The cultivated area amounts to 1,435,859 acres, of which 762,830 are under rice. Muzaffarpur suffered severely from the famines of 1866 and 1874.

MUZAFFARPUR, chief town and administrative headquarters of the above district, is situated on the right or south bank of the Little Gandak river in 26° 7′ N. lat. and 85° 26′ E. long., with a population (1881) of 42,460. The town is clean, with many broad and well-kept streets; it has a good collectorate and court-houses, jail, dispensary, and several good schools. A large trade is carried on both by road and river. The town, however, is liable to inundation, and suffered severely from this cause in 1871.

MUZIANO, GIROLAMO (1528-1590?), an eminent Italian painter, was born at Acquafredda near Brescia in 1528. Under Romanino, an imitator of Titian, he studied his art, designing and colouring according to the principles of the Venetian school. But it was not until he had left his native place still in early youth, and had repaired to Rome about 1550, that he came into notice. There his pictures soon gained for him the surname of *Il Giovane de' Paesi* ("the young man of the landscapes"); chestnut-trees are predominant in these works. He next tried the more elevated style of historical painting. He imitated Michelangelo in giving great prominence to the anatomy of his figures, and became fond of painting persons emaciated by abstinence or even disease. His great picture of the Resurrection of Lazarus at once established his fame. Michelangelo praised it, and pronounced its author one of the first artists of that age. It was placed in the church of Santa Maria Maggiore, but was afterwards transferred to the Quirinal palace. Muziano, with dogged perseverance (at one time he shaved his head, so as not to be tempted to go out of doors), continued to proceed in the path on which he had entered. He grew excellent in depicting foreign and military costumes, and in introducing landscapes into his historical pieces after the manner of Titian. Mosaic working also occupied his attention while he was employed as superintendent at the Vatican; and it became under his hands a perfect imitation of painting. His ability and industry soon gained for him a handsome fortune. Part of this he expended in assisting to found the Academy of St Luke in Rome. He died in 1590, or, according to another authority, in 1592, and was buried in the church of Santa Maria Maggiore.

Many of Muziano's works are in the churches and palaces of Rome; he also worked in Orvieto and Loreto. In Santa Maria degli Angeli, Rome, is one of his chief works, St Jerome preaching to Monks in the Desert; his Circumcision is in the church of the

Gesù, his Ascension in the Araceli, and his St Francis receiving the Stigmata in the church of the Conception. A picture by him, representing Christ washing the feet of his disciples, is in the cathedral of Rheims.

MYCENÆ, one of the most ancient cities of Greece, was situated in the north-eastern extremity of the fertile Argive plain—μυχῷ Ἄργεος ἱπποβότοιο. Its situation is exceedingly strong, and it commands all the roads leading from Corinth and Achaia into the Argive plain; this fact, combined with its distance from the sea, shows that the city was founded by a race which came from the direction of Corinth and not by immigrants landing on the coast. The walls of Mycenæ are the greatest monument that remains of the Heroic age in Greece; part of them is similar in style and doubtless contemporary in date with the walls of the neighbouring town Tiryns, but other parts seem to be the work of a rather later time. There can therefore be little doubt that the two towns were the strongholds of a single race, Tiryns commanding the sea-coast and Mycenæ the inner country. The city of Argos, on the other hand, has no remains to connect it with this early Mycenæan race; and legend tells of the rivalry between the dynasties of the Pelopidæ at Mycenæ and of the Prœtidæ at Argos. The long warfare between the two cities lasted till 468 B.C., when Mycenæ was dismantled and its inhabitants dispersed. The city never revived; Strabo asserts that no trace of it remained in his time, but Pausanias describes the ruins.

Subjoined are the most important monuments 1. The "Treasuries" of Atreus and his sons, as Pausanias calls them. They were subterranean buildings of beehive shape, in the side of the hill south-west of the city; one of them is still almost perfect. A sloping passage, δρόμος, led to the doorway, with its ornamented columns, at the base of the building. The great circular chamber inside was probably covered with plates of bronze; a door in one side admitted to a second smaller chamber. Such buildings, which are found in other parts of Greece—e.g., Orchomenus, Spata in Attica, Iolcus, &c.—were undoubtedly the sepulchres of noble families

2. The graves discovered by Dr Schliemann in 1876 within the city wall. They are enclosed within a circular περίβολος with a single entrance, and the place was therefore a holy place in the ancient Mycenæan time; on the other hand the part of the city wall which encloses them is a later addition to the original wall. At some period before 468 B.C. this addition was built; before that time the περίβολος was outside the wall. Some heroes of the race were worshipped here by the ancient inhabitants, but their names are not recorded by any trustworthy authority. In the time of Pausanias, six centuries after Mycenæ was destroyed, local legend maintained that these were the graves of Atreus, Agamemnon, Cassandra and her children, and Eurymedon; but it is uncertain whether this was the original legend, or a later tale that grew under the influence of Greek literature.

3. The Lion-Gate. The principal entrance to the city is approached by a δρόμος, flanked on each side by the city wall and leading up to a gateway. Over the entrance is placed a triangular slab of stone on which are carved two lions in relief; they are rampant, facing one another, but separated by an upright column. The art of this relief shows no resemblance to archaic Greek art; it is foreign in character, the work of an immigrant race, which brought with it a well-developed civilization.

Greek legend always maintains that the Pelopidæ of Mycenæ came from Phrygia, and this is corroborated by the evidence of archæology. The objects found in excavations, and the sculptured ornament on the doorways of the "Treasuries" and over the Lion-Gate, all point to foreign influence and particularly to Asia Minor. The same type of the two lions and the column has been recently found over the entrance to a colossal sepulchre in the rocks near the south-western corner of the Sangarius valley in Phrygia. Legend and remains alike show that a rich and powerful dynasty of foreign origin ruled at Mycenæ; the only early remains in the Greek world that equal them in interest are the ruins of ancient Troy. It is precisely these two cities which are described in the Homeric poems as the two great cities of the Greek world.

MYDDLETON, SIR HUGH (*c.* 1555-1631), the projector of the New River scheme for supplying London with water, was the sixth son of Richard Myddleton, governor of Denbigh Castle in the reigns of Edward VI., Mary, and Elizabeth. Hugh Myddleton became a goldsmith in London, occupying a shop in Bassihaw (now Basinghall) Street, and he is also mentioned in the records of Denbigh, for which he was chosen M.P. in 1603, as a merchant adventurer. In the state papers there is an entry of £250 paid to him for a jewel supplied to the queen. In connexion with his business as goldsmith Myddleton worked silver and lead mines in Cardiganshire, and in this way obtained the practical knowledge of engineering which enabled him to put in operation his scheme for supplying London with water (see LONDON, vol. xiv. p. 825). In recognition of his services he was created a baronet by James I. in 1622; but pecuniarily the enterprise was a complete failure. Myddleton died 10th December 1631, and was buried in the churchyard of St Matthew, Friday Street, London. See Pinks, *History of Clerkenwell.*

MYELITIS (μυελός, marrow) is a disease which by inflammation induces destructive changes in the tissues composing the spinal cord. In the *acute* variety the nerve elements in the affected part become disintegrated and softened, but repair may take place; in the *chronic* form the change is slower, and the diseased area tends to become denser (sclerosed), the nerve-substance being replaced by connective tissue. Myelitis may affect any portion of the spinal cord, and its symptoms and progress will vary accordingly. Its most frequent site is in the lower part, and its existence there is marked by the sudden or gradual occurrence of weakness of motor power in the legs (which tends to pass into complete paralysis), impairment or loss of sensibility in the parts implicated, nutritive changes affecting the skin and giving rise to bed-sores, together with bladder and bowel derangements. In the acute form, in which there is at first pain in the region of the spine and much constitutional disturbance, death may take place rapidly from extension of the disease to those portions of the cord connected with the muscles of respiration and the heart, from an acute bed-sore which is very apt to form, or from some intercurrent disease. Recovery to a certain extent may, however, take place; or, again, the disease may pass into the chronic form. In the latter the progress is usually slow, the general health remaining tolerably good for a time, but gradually the strength fails, the patient becomes more helpless, and ultimately sinks exhausted, or is cut off by some complication. The chief causes of myelitis are injuries or diseases affecting the spinal column, extension of inflammation from the membranes of the cord to its substance (see MENINGITIS), exposure to cold and damp, and occasionally some pre-existing constitutional morbid condition, such as a fever. Any debilitating cause or excess in mode of life will act powerfully in predisposing to this malady. The disease is most common in adults. The treatment for myelitis in its acute stage is similar to that for spinal meningitis. When the disease is chronic the most that can be hoped for is the relief of symptoms by careful nursing and attention to the condition of the body and its functions. Good is sometimes derived from the employment of electricity, and the use of baths and douches to the spine.

MYNPOOREE. See MAINPURÍ.

MYRIAPODA. The Myriapoda or Centipedes are usually treated of in text-books as one of the classes of the group Arthropoda, being associated in that group with the Crustacea, Arachnida, and Insecta as equivalent divisions of the animal kingdom. In consequence, however, of recent evidence which points to a community of origin of all the Tracheate forms apart from that of the Crustacea, it is probably more natural to divide the Arthropoda (with the exception of certain minor groups of obscure affinities) into two classes, one consisting of the Crustacea, the other of the Tracheata. If this plan of classification be adopted, the Myriapoda form a sub-class of the Tracheata. It is necessary that the peculiar contrast in structure between

the remarkable genus *Peripatus* and all other Tracheata should be clearly indicated in any systematic arrangement. *Peripatus*, an account of which, in consequence of its important relations to the Myriapoda, is given in the present article, has been variously placed by systematists as constituting a separate class of the Arthropoda, the "Protracheata," or as worthy of higher or lower rank than indicated by such position. It will be regarded here as representing a special sub-group of the Tracheata—the Protracheata as opposed to the remaining Tracheates or Eutracheata—thus:—

Arthropoda.	Class— CRUSTACEA.		
	Class— TRACHEATA.	Group— *Protracheata.*	Sub-class— Peripatidea.
		Group— *Eutracheata.*	Sub-class— Myriapoda. Insecta. Arachnida.

Linnæus included the Myriapoda in his Insecta Aptera, together with the Crustacea and Arachnida. In 1779 Fabricius first separated the Myriapoda as a distinct order under the name Mitosata, but still retained several separate orders of Crustacea as equivalent. In 1796 Latreille divided the Aptera of Linnæus into seven orders, one of which was constituted by the Myriapoda (so first named by him), but he included with them the Isopoda. In 1800 Cuvier and Lamarck first separated Linnæus's Insecta into three primary natural classes, creating the Crustacea and retaining as the two others the Arachnida and Insecta. In 1825 Latreille, finally following Leach (1815), set up the Myriapoda as a fourth class, separating them from the Insecta connected with them. Subsequently the class Myriapoda was a constant source of controversy amongst naturalists, and many attempts were made to overthrow it altogether. Thus the Myriapoda were connected by Macleay with the Insecta, and also by Kirby in 1826, further by Burmeister in 1837, and by Von Siebold with Crustacea in 1848

The PROTRACHEATA may be defined as—

Tracheata with imperfectly-jointed appendages, and numerous stigmata indefinite in number, scattered in various regions of the body; the first pair of post-oral appendages only modified to act as jaws; the second pair rudimentary, bearing the opening of the duct of a slime-gland; remaining pairs numerous, all alike; ambulatory legs, each provided with a pair of claws; no definite infra-œsophageal nerve-ganglion; ventral nerve-cords imperfectly ganglionated, widely divaricated, united posteriorly dorsad of the rectum; complicated segmental organs present, opening at the bases of the legs; arch-enteron in the embryo formed by invagination; a wide slit-like blastopore formed in the embryo, which gives rise to the mouth anteriorly and anus posteriorly.

The sole representatives of this group of the Tracheata are the seven or eight known species of the genus *Peripatus* (fig. 1). These are soft-

FIG. 1.—Large adult example of *Peripatus capensis* of natural size. (From Moseley.)

bodied animals very like lepidopterous caterpillars in form, of a brown or blackish colour, with a series of pairs of short conical legs placed laterally at equal intervals along the entire length of the ventral surface behind the mouth. The legs in advanced embryos show a distinct division into five joints by transverse constrictions, but in the adults this jointing is much obscured. The skin not being protected by chitinous plates, but only by fine papillæ armed with chitine, no definite hinge-joints are formed comparable to those so usually present in other Tracheata. The terminal joint of each leg or foot is provided with a pair of curved claws. The number of legs present varies in the different species. The head bears a pair of simple eyes and a pair of antennæ composed of very numerous joints. The first pair of legs, which in the embryo closely resembles those developed behind it (fig. 2), becomes in the process of development turned in in front of the mouth, and its claws become modified into a pair of sickle-shaped toothed jaws which work against one another in front of the mouth, and are completely enclosed in the adult in a wide buccal cavity. This cavity opens to the exterior ventrally on the under side of the head by the buccal aperture, which is oval in form and is surrounded by tumid lips, and has often been described as the mouth, although the true mouth lies within the buccal cavity underneath the jaws (figs. 3, 4).

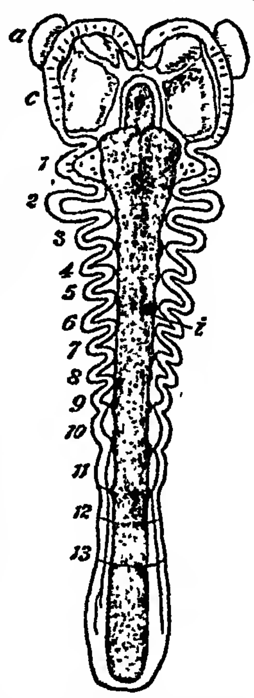


FIG. 2.—Early embryo of *Peripatus capensis* uncoiled (from Balfour, after Moseley). *a*, antennæ; *c*, procephalic lobe; *i*, intestine; *o*, mouth; 1, 2, 3, &c., post-oral appendages.

The second pair of appendages of the embryo becomes converted in the adult into a pair of short papillæ,—the oral papillæ, which bear at their tips the openings of a pair of large glands secreting a viscid substance. Respiration is effected in *Peripatus* by means of an immense number of small tracheal tufts. Each of these tufts consists of a short tubular chamber or sac, opening at one end, which is narrowed, to the exterior by a minute simple aperture (*stigma*) in the cuticle, and provided at its opposite enlarged extremity with a tuft of very fine air-tubes. In these fine tracheal tubes only a very faint indication of an imperfect spiral thickening of the chitinous lining membrane can be detected. The tubes are, with very rare exceptions, unbranched; they are finely distributed to the various muscles, viscera, &c. These tracheal tufts closely resemble in structure those of the Diplopod Myriapoda, but their disposition differs from that occurring in all other Tracheata. Instead of a definite small number of stigmata only being present, placed in definite positions on the successive somites, an indefinite number is present in *Peripatus*. Certain of these are scattered irregularly over the whole body-surface, whilst others are concentrated more or less thickly in a double row on each side of the dorsal median line, in a corresponding double ventral row, and further on the anterior and posterior aspects of the legs and round the bases of the legs. A series of segmental organs is present, a pair for each pair of legs. They are coiled tubes opening at one end into the body cavity and at the other to the exterior at the bases of the legs on their inner or ventral aspects.

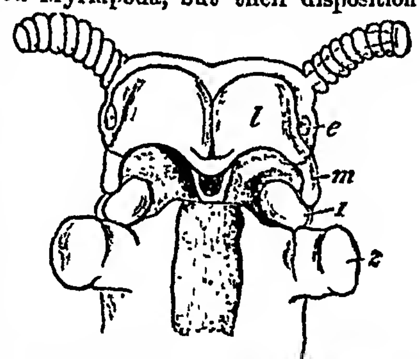

FIG. 3.—Ventral view of the head of a more advanced embryo of *Peripatus capensis* (from Balfour, after Moseley). *e*, eye; *l*, thickening of epiblast of procephalic lobe to form supra-œsophageal ganglion; *m*, process from procephalic lobe growing over the first post-oral appendage; *o*, mouth; 1 and 2, first and second pairs of post-oral appendages, becoming later the jaws and oral papillæ respectively.

The nervous system consists of a pair of supra-œsophageal ganglia fused together in the middle line, from which arise the ventral cords, which remain widely divaricated throughout the length of the body to its hinder extremity, where they unite above the dorsal surface of the rectum. The ventral cords appear at first without ganglionic enlargements, but in reality rudimentary ganglionic swellings are present on them corresponding with the origins of the nerves for the jaws, oral papillæ, and all the legs. They

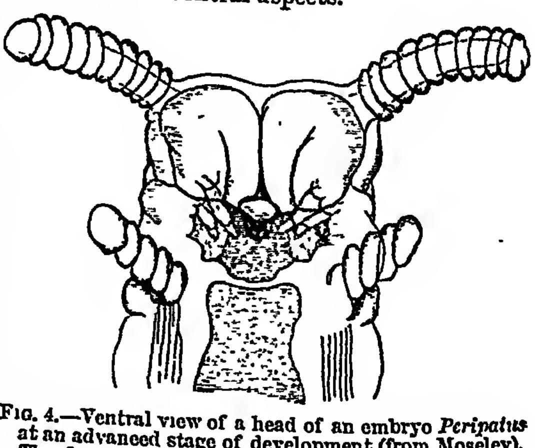

FIG. 4.—Ventral view of a head of an embryo *Peripatus* at an advanced stage of development (from Moseley). The figure shows the jaws (the modified pair of claws of the first pair of appendages) turned in towards the mouth, the dark spot between them, which together with them is enclosed by the wall of the buccal cavity. The second post-oral appendages or oral papillæ are seen to be distinctly five-jointed.

are connected by fine transverse commissures forming a so-called rope-ladder nerve-system. Visceral nerves are present, with an arrangement similar to that in Chætopods rather than that found in Arthropoda. A dorsal and a ventral blood-vessel are present. The dorsal vessel is, according to Gaffron, a true muscular heart provided with a pair of dorsally-placed valvular openings on each segment of the body, but without any trace of vessels in connexion with these. It lies as in other Tracheata in a pericardial sinus formed by a horizontally-stretched septum, and especially approaches in its general structure the corresponding organ of Diplopoda.

The ovary in the female is closely similar to that of *Lithobius* in structure. The animal is viviparous, and the pair of long oviducts function as uterus. In the male the spermatozoa are long and filiform, exactly like those of *Lithobius*. They are actively mobile, and perform exactly the same movements as those of *Lithobius*, and, as in that genus, are formed into rod-like spermatophores.

In its embryological development, which cannot here be followed, conclusions as to the affinities of *Peripatus* with the Tracheates receive strong confirmation. Early embryos of *Peripatus* bear a remarkable resemblance to those of scorpions, spiders, and Myriapods, and the mode of formation of the procephalic lobes, nerve-system, and limbs is closely similar. The five-jointing of the limbs of the embryo of *Peripatus* is remarkably similar to that occurring in embryo spiders, such as *Agelena*. In one important respect the embryonic history of *Peripatus* differs most remarkably from that of all other Tracheata, as far as is known. A large, open, slit-like blastopore is, as discovered by Balfour, formed in the very early embryo of *P. capensis*. This slit closes in its centre, and its anterior extremity apparently remains permanently open as the mouth, whilst its posterior region persists as the anus In the embryos of other Tracheates the only representative of this no doubt ancestral mode of development surviving is the so-called mesoblastic groove.

The species of *Peripatus* live in moist places, in hollows in decayed wood, and under stones and logs. The animals walk with a gait similar to that of caterpillars, with their bodies completely supported from the ground by their legs. When irritated they eject from their oral papillæ fine jets of the viscid slime secreted by their slime-glands. These fine jets form networks of fine threads, looking like a spider's web, which cling to the fingers with the tenacity of bird-lime. The New Zealand species is said to catch insects for food by means of these slime-jets. The animals roll themselves up like *Julus* when quiescent. They appear to be nocturnal in habits.

The group *EUTRACHEATA* may be thus defined—

Tracheata of various form, usually with completely jointed appendages; never bearing diffuse stigmata indefinite in number, but with not more than two pairs on each somite; ventral nerve-cords closely approximated, with well-marked infra-œsophageal ganglion, never united posteriorly dorsad of the anus; no segmental organs present; no blastopore formed in the embryo; mouth and anus formed as a stomodæum and a proctodæum respectively.

The sub-class MYRIAPODA may be defined as follows—

Eutracheata with a head distinctly separate from the numerous closely similar posterior somites, with a pair of antennæ and two pairs of jaws; with numerous similar jointed walking legs; Malpighian tubes present.

The Myriapoda, like *Peripatus*, approach the Annelids in having elongate bodies, either cylindrical or more or less flattened, composed of numerous similar joints or somites. They bear numerous pairs of walking legs on the somites posterior to the head, and in this particular differ most markedly from all insects except some of the most primitive forms, such as the *Campodeidæ*, which approach them by the possession of rudimentary abdominal legs, and with which, as will be described, they are possibly connected to some extent by such a form as *Scolopendrella*. Some forms (*Glomeridæ*) most remarkably resemble woodlice in shape, and hence Latreille's connexion, already referred to, of the Myriapoda with the Isopodous Crustacea. The head of Myriapoda is very like that of Insecta, and bears a single pair of antennæ, the eyes when present, and two pairs of jaws. The first pair of jaws, the stout toothed mandibles, are, as in insects, always devoid of palps, but in nearly all cases they are jointed, a primitive condition not occurring in insects. The second pair, the maxillæ, are fused together to form a sort of under-lip. In one aberrant family (*Polyzonidæ*) the mouth parts are formed into a tubular pricking and sucking apparatus. The body behind the head is composed of distinctly separated similar segments, usually numerous (in *Pauropus* nine only). There is no division of the body into thoracic and abdominal regions. The ventral nerve-cord stretches the entire length of the body, and is provided with a ganglion more or less distinct for each somite. The first three of its ganglia are fused together. Eyes are wanting in some forms, in others they are present on the sides of the head as simple ocelli or groups of ocelli. In one form only (*Scutigera*) are they compound and facetted. The structure of the ocelli differs remarkably from that of the simple eyes of spiders, in that the crystalline rods in each ocellus are so placed that their axes lie parallel to the plane of the equator of the simple lens, at right angles to the optic axis of the eye instead of in its direction. They are also not isolated by pigment. Grenacher hence concludes that it is impossible that any definite image can be formed on the rods, so as to convey any impression of it to the retinal cells with which they are in connexion. Hence these eyes must discriminate only variations in intensity of light. In *Scutigera* the internal structure of the eyes, though closely simulating that of the compound eyes of insects in many details, is in reality very peculiar and different from that in all other Arthropods. The digestive canal is simple and straight, except in *Glomeridæ*, and ends in a terminal anus. At the commencement of that portion which acts as a rectum, and which in the embryo is formed from the proctodæum, two or four long coiled urinary tubes (*Malpighian tubes*), homologous with those of insects, open into it. There is a dorsal tubular heart, divided into a series of chambers corresponding with the somites, and, as in insects, contained within a blood sinus (pericardium), formed by a horizontal septum stretched across the body-cavity, and provided with a series of pairs of wing-like muscles (*alæ cordis*), by which the sinus-cavity is dilated. Respiration is effected by means of air-tubes or tracheæ as in insects. In the Diplopoda, excepting the *Glomeridæ*, in which they are ramified as in the Chilopoda, these are of essentially the same structure as in *Peripatus*, viz., tufts of unbranched tubes with feebly-developed spiral filaments springing from a common short sac-like chamber (fig. 5). Four of these sac-like chambers

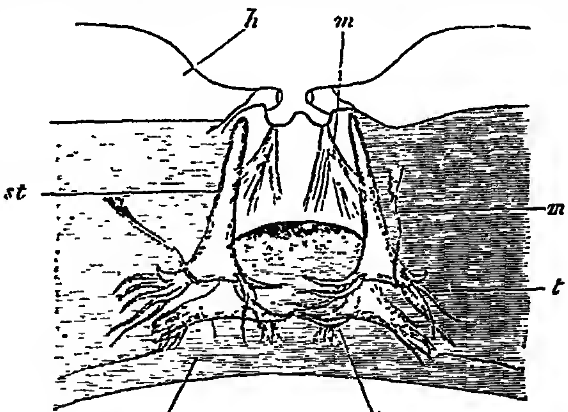

FIG. 5.—Inner view of the sterna of a single segment of *Julus londinensis*, much enlarged to show the structure and arrangement of the tracheal organs (after Voges). The two pairs of tracheæ are seen in situ, the posterior pair overlapping the anterior. *h*, posterior margin of the body-ring (tergum); *r*, anterior border; between the two lie the two terga; *st*, tubular chamber of tracheæ; *t*, fine tracheæ given off from it; *ms*, respiratory muscle attached to tracheal sac; *m*, ventral body muscle.

open on the ventral surface of the body by means of two pairs of stigmata on each somite. In the Chilopods wide tracheal tubes with well-devéloped spiral thickening of their lining membrane, springing directly from the stigmata, freely branching, and often anastomosing like those in insects, are always present. In all cases single pairs of laterally-

placed stigmata only are present on each somite. In the aberrant *Scolopendrella* possibly a single pair of stigmata only are present on the sides of the head, and in *Scutigera* there are only seven unpaired stigmata present in the middle dorsal line. In this latter form the tracheæ proceeding from the stigmata are very short; they branch a few times dichotomously, and then terminate in blind enlargements. From these the air is conveyed throughout the body in connexion with the fat bodies and peculiar folds of membrane as far as into the tarsi, the arrangement thus approaching somewhat that of the tracheal lungs of Arachnida. Remarkable glandular structures provided with ducts opening to the exterior occur in various Myriapoda. In all the Diplopoda there are rows of apertures placed laterally one on each somite on either side of the body, known as *foramina repugnatoria*, because each acts as the opening of the duct of a gland producing an acrid offensive fluid, which is discharged by the animal on irritation. In a species of *Fontaria*, one of the *Polydesmidæ*, as has been recently discovered, this secretion contains a chemical body, probably benzol and petroleum ether, which readily breaks up into prussic acid, and another substance, probably benzaldehyde. The animal thus, when irritated, smells strongly of prussic acid. Similar glands are wanting in most Chilopods, but in *Geophilus Gabrielis* there are a series of glands opening to the exterior by means of a series of perforated chitinous plates placed ventrally in the median line, which discharge a red fluid, probably of a similar defensive nature.

The foramina repugnatoria of the Diplopods were by early observers mistaken for stigmata, as they correspond in position with the stigmata of the Chilopods. It is worthy of note that, if Moseley's hypothesis that tracheal organs have arisen in evolution as modifications of universally scattered cutaneous glands is correct, the lateral foramina repugnatoria and glands of the *Julidæ* may be after all to some extent homologous with the lateral stigmata and tracheæ of the *Scolopendridæ*, the ventral tracheæ of the *Julidæ* with the ventral glands of *Geophilus Gabrielis*, whilst the dorsal stigmata of *Scutigera* represent the survival of part of the dorsal tracheæ of an ancestral form, with scattered tracheæ like *Peripatus*. In some derived forms the glands have survived as tracheæ in one region of the body, in others in another region, in some certain of them have remained as glands or reverted to that condition, in others they have developed into enlarged tracheæ.

The generative organs of the Myriapoda are usually elongate, unpaired, tubular organs, often with paired ducts, always provided with accessory glands, and in the female often with a receptaculum seminis. In the Chilopods the ducts open at the hinder extremity of the body; in the Diplopods on the ventral surface of the third somite posterior to the head.

The Myriapoda are usually divided into two orders—the Diplopoda and the Chilopoda. Of these the former appears to be the most ancient and primitive, as proved by its general structure, and especially by that of its tracheæ, and by geological evidence so far as knowledge extends. They may be thus characterized.

Order Diplopoda (= Chilognatha).

Myriapoda with bodies circular or semicircular in section; antennæ short, of no more than seven joints; no appendages acting as poison-claws; each somite in the middle and hinder region of the body bearing two pairs of legs; a variable small number of anterior somites always bearing single pairs only; stigmata ventral, two pairs to each somite; tracheal organs tuft-shaped with sac-like main tube, not branching or anastomosing; laterally-placed repugnatorial glands present; a single pair of Malpighian tubes present; generative organs opening on the third post-cephalic somite; larvæ at birth provided with only three pairs of functionally active legs.

In the genus *Julus*, the well-known Millepedes, which may be taken as types of this order, the body is nearly cylindrical, slightly flattened beneath, and composed of a series of chitinous rings, one to each somite, which are bevelled off at their posterior borders for a certain part of their breadth so as to fit each within the next succeeding ring (fig. 6). The rings ("terga") are not complete, but interrupted by a narrow interval corresponding with the ventral median line, which is closed in each ring by a pair of ventral plates ("sterna") placed one in front of the other. Each of these ventral plates, except in the first four post-oral somites, bears a pair of short jointed legs composed each of five joints and a single terminal claw, the bases of the legs of opposite sides being so closely approximated in the middle line as to be in contact. Just in front of the base of each leg is a simple stigma communicating with a tuft-shaped tracheal organ (fig. 5). There are thus two pairs of legs to all except the most anterior somites, and two pairs of tracheæ. The mandibles mostly have broad chewing surfaces suited to mastication of vegetable matter. The maxillæ of the two sides are fused together to form a four-lobed plate acting as an under-lip. There are no poison-claws as in the Chilopods, but the leg-shaped appendages of the first post-cephalic somite, the tergum of which is in most forms enlarged and shield-like, are turned towards the mouth, and probably assist in the process of feeding. In the males of some forms these appendages are shaped into peculiar short blunt grasping hooks, bearing spines on their bases (fig. 7). Of the succeeding three somites one (the third post-cephalic) is devoid of legs; and also of sternal plates; the other two bear a single pair of legs each only. The remainder of the somites bear each two pairs of legs (hence the term Diplopoda), except the seventh post-oral in the male, on which a complicated paired copulatory organ, formed out of modifications of the sterna and other components of the normal somite, is present. The form of these copulatory organs varies very much in species and genera of Diplopoda, and is of great systematic value. In both male and female *Julus* the generative ducts open by a pair of apertures on the ventral surface of the third segment, just behind the bases of the second pair of legs, the copulatory organs in the male being without internal connexion with the ducts of the testis.

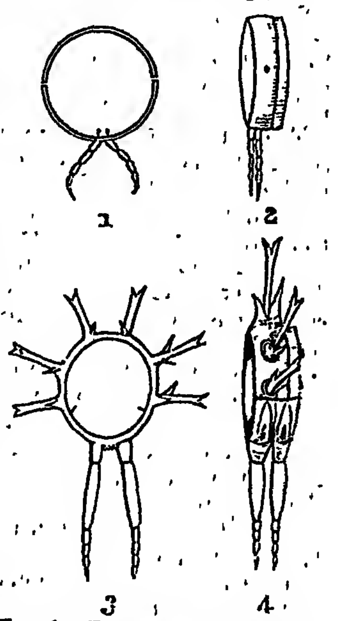

FIG. 6.—Diagrams of the structure of recent and certain Palæozoic Diplopoda (after Scudder). 1, cross section of a recent; 3, of a Palæozoic Diplopod; 2, side view of a somite of a recent; 4, of a Palæozoic Diplopod. In 1 and 3 the space occupied by the sterna is indicated by fine lines projecting within the rings; it is very narrow in 1, broad in 3. In 2 and 4 the posterior bevelled border of the somites lies to the right. In 1 and 2 the foramina repugnatoria are shown.

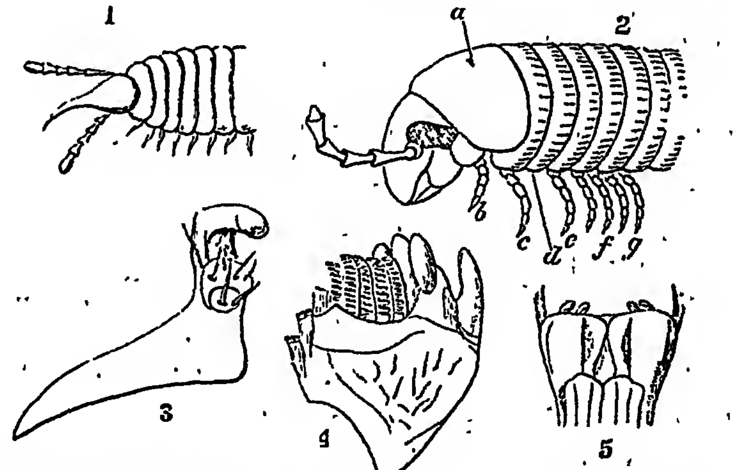

FIG. 7.—1, head and anterior somites of *Siphonophora portoricensis* (after Koch). 2, diagram of the arrangement of the anterior somites and appendages of the female *Julus londinensis* (original). *a*, modified tergum of first post-oral somite (dorsal-plate or collum); *b*, short single appendage of same somite, of four joints and a claw only, turned towards the mouth; *c*, single appendage of second somite of five joints and a claw like the remaining appendages; *d*, third or generative somite devoid of appendages and sterna, but bearing the generative apertures; *e*, single appendage of fourth somite; *f*, *g*, dual appendages of succeeding somites. 3, hook-like first post-cephalic appendage of male of same attached to its plate of support (= one-half of modified sternum?). 4, mandible of same. 5, the four-lobed plate formed by the fused single pair of maxillæ.

The *Julidæ* coil themselves up spirally when at rest or when attacked, like *Peripatus*. The whole of the Diplopods are vegetable

feeders. In the tropics very large representatives of the *Julidæ* occur, especially species of the genus *Spirobolus*, which do considerable damage in gardens by devouring leaves. In the *Polyzonidæ* (fig. 7) the mouth parts are formed into a pricking and sucking beak or tube. In the *Polydesmidæ* the body is semi-cylindrical in section, with the lateral regions of each tergum broadened out into a pair of horizontal projecting plates. In the Palæozoic Diplopoda, *Euphorberia* and its allies, the terga bore each six stout projecting spines, forming rows of spines along the body (fig. 6); the sterna enclosed one-third of the circuit of the body instead of only an insignificant ventral streak as in the *Julidæ*. In addition to the stigmata there are found on the ventral aspect of these fossil forms certain paired organs supposed by Scudder, who conjectures that these ancient Diplopoda may have been amphibious in habits, to have given support to gills. In the *Glomeridæ* the body is shortened, of twelve or thirteen somites only, and closely simulates that of the woodlouse in appearance. The males of *Sphærotherium*, a genus of this family, possess a stridulating apparatus at the hinder end of the body

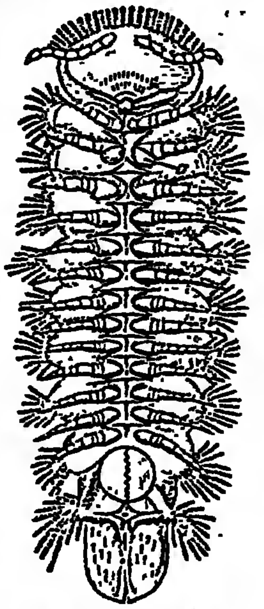

FIG. 8.—Ventral view of *Polyxenus lagurus* (after Bode) much enlarged, actual length a little over 1/12th of an inch. *a*, position of generative openings.

Very important from a zoological point of view are the genera *Polyxenus* and *Pauropus*, the species of both of which are extremely small. *Polyxenus* (fig. 8) is about one-twelfth of an inch in length, and has fourteen pairs of legs, only the first four pairs of which are borne on the first four post-cephalic somites. The body is covered with bundles of hairy scales. In *Pauropus* (fig. 9) only nine pairs of legs are present. The antennæ are branched at their tips; the first post-cephalic somite bears a single pair of legs, the second post-cephalic a single

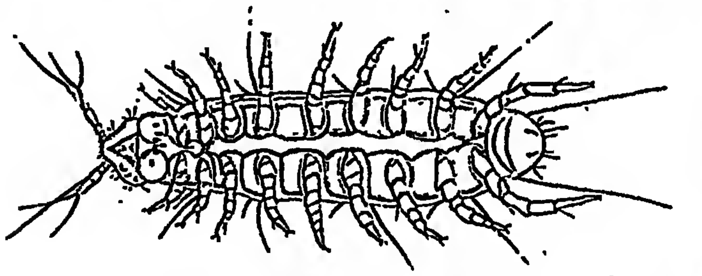

FIG. 9.—Enlarged view of *Pauropus Huxleyi*. (After Lubbock.)

pair of legs, and the remaining somites, except the posterior which bears a single pair, two pairs each. Sir John Lubbock, the discoverer of this form, which has many aberrant features besides those described above, referred it to a separate order of Myriapods, *Pauropoda*.

Order Chilopoda.

Myriapoda mostly of dorso-ventrally compressed form, with long multi-articulate antennæ; with the second pair of post-cephalic appendages applied to the mouth as poison-claws; only one sternum and one pair of legs to each somite; stigmata lateral (in *Scutigera* dorsal); tracheal organs ramified, not tuft-shaped, often anastomosing; generative openings posterior; larvæ born with more than three pairs of functionally active legs.

In *Scolopendra* (fig. 10) the body is band-like and flattened dorso-ventrally. The terga and sterna are nearly flat broad plates of chitinous material, connected laterally by more flexible softer skin, in which in each somite lies on either side a single stigma. The corresponding large ramified tracheal trunks, which are provided internally with well-developed spiral filaments, are connected on each side by lateral longitudinal anastomosing tubes. The antennæ are many-jointed, long, and tapering; the head is followed by a second compound somite formed of four embryonic somites fused, termed the "basilar somite," which is covered by a single enlarged shield-like tergum. The legs are borne at the lateral margin of the ventral surface, their bases being wide apart; one pair is present to every post-basilar somite. The mandibles are provided with sharp cutting teeth; the maxillæ are fused together in the middle line as in Diplopods. They do not form a plate, but in the centre a small bilobed process only, and bear a pair of soft palps laterally (fig. 11). The basilar somite bears as the first pair of post-cephalic appendages a pair of palp-like legs turned forwards in front of the mouth, and as the second a pair of large powerful limbs, the poison-claws, provided with a pair of curved claws perforated at their extremities by the ducts of poison-glands embedded in the claws and their penultimate joints. The basilar somite may bear posteriorly in addition a pair of walking legs, but this pair is frequently aborted in the adult animal. The last pair of legs at the hinder extremity of the body is elongated and directed backwards in the line of the body posteriorly. The generative ducts open posteriorly beneath the anus.

The Chilopoda are all carnivorous, catching their prey and killing it by means of the poison-claws. *Eucorybas crotalus* of S. Africa makes with its hind legs a rattling noise like that of the rattlesnake. *Arthronomalus longicornis* of Europe is phosphorescent in the dark. The

FIG. 10.—*Scolopendra morsitans* (after Buffon). *a*, cephalic tergite; *b*, basilar tergite; *c*, first post-cephalic appendage (=third post-oral); *d*, third post-cephalic; *e*, antenna; *f*, second post-cephalic (=poison-claws); *g*, last pair of appendages enlarged and directed backwards.

FIG. 11.—Mouth parts of *Scolopendra morsitans* (after Buffon). 1, the poison-claws or fourth post-oral appendages; *s*, median cutting processes formed by the anterior edge of the basilar sterna; 2, one of the mandibles with its cutting edge to the left; 3, the maxillæ and third post-oral appendages *a*; *c*, palp-like maxillæ; *b*, small process formed by their fused bases; 4, ventral view of head with jaws removed; *α*, eyes; *e*, labrum.

Geophilidæ, which are without eyes, have very long worm-like bodies, composed of very numerous segments. They live gregariously in moist earth. In *Lithobius*, the commonest British Centipede, the somites are unequal in size, there being nine larger and six smaller terga and fifteen legs composed each of six joints and a claw. The genus *Scutigera* and its allies form a remarkable family, *Scutigeridæ* (fig. 12), in which the antennæ are bristle-like and as long as the body, and the legs are extremely long, increasing in length towards the hinder end of the body. The peculiarities

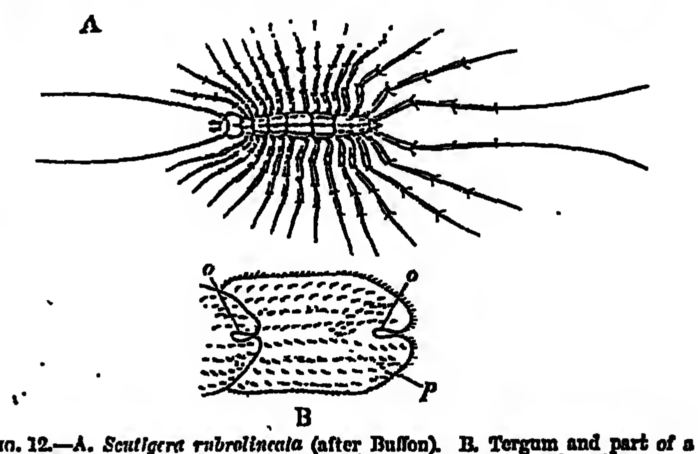

FIG. 12.—A. *Scutigera rubrolineata* (after Buffon). B. Tergum and part of a second of the same enlarged to show the position of the stigmata *o*, *o*; *p*, hinder margin of tergum.

of their eyes and respiratory organs have already been referred to above. Most important is the aberrant genus *Scolopendrella*, which has lately been shown to have certain marked features indicating alliance to the primitive insects, *Thysanura*. The species of *Scolopendrella* are minute forms five or six mm. in length, appearing (fig. 12), as indicated by the name, at first sight like small *Scolopendras* (fig. 13). The head and antennæ nearly resemble those of *Campodea*. The body bears, according to Wood Mason, dorsally fifteen tergites behind the head, the first of these being quite rudimentary. Ventrally thirteen corresponding indications of somites only can be detected; and these bear twelve pairs of functional appendages. Two of the tergites appear to be devoid of sternites and appendages. The first post-cephalic appendages (= third post-orals) are small and turned towards the mouth; the eleven following ventrally-indicated somites bear each, besides a pair of functional

ambulatory legs, a second pair of rudimentary appendages lying internally to these latter. The legs are five-jointed and bear each a pair of claws as in *Campodea* and *Peripatus* instead of a single claw as in other Myriapoda (*Lithobius* sometimes bears a pair on the anal legs only). There is a pair of caudal stylets on the last somite perforated by the ducts of silk glands. The arrangement of the stigmata is uncertain. Hasse finds only a single pair on the head, Wood Mason and others many pairs on the body somites. Peculiar paired segmental organs are present on the ventral surface which may be excretory. It appears not impossible that *Scolopendrella* may have originally possessed two pairs of appendages to each somite, and may thus represent to some extent a transition form between the ancient Diplopoda and the more recent Chilopodous type; but as the anatomy of *Scolopendrella* is as yet imperfectly known, and nothing is known as to its embryonic development, its place in classification must remain for the present an open question. By Ryder a separate order (*Symphyla*) has been formed for it, whilst Packard has placed it amongst the *Thysanura* notwithstanding its numerous jointed legs, which constitute the most essential distinction of Myriapoda from Insecta.

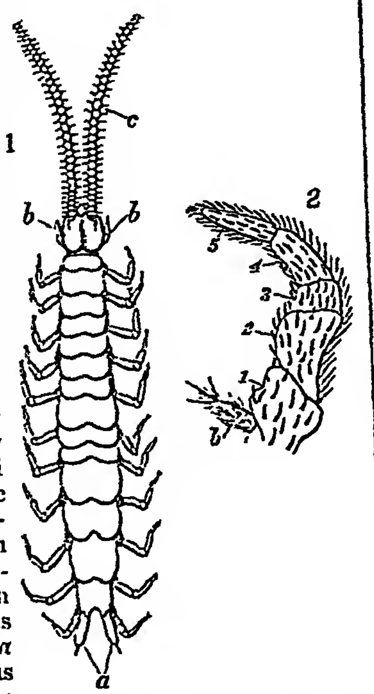

Fig. 13.—1, *Scolopendrella immaculata* highly magnified (slightly modified from Packard); *a*, caudal stylets; *b*, *b*, first post-cephalic appendages; *c*, antennæ; 2, one of the functional legs further enlarged (from Wood Mason), showing the five joints and terminal pair of claws; *b*, inner rudimentary leg of same somite.

Remains of representatives of the Chilopoda have not been found in Palæozoic strata. The earliest known are Secondary from the Solenhofen slate.

Development of the Myriapoda.—*Scolopendra* is viviparous like *Peripatus*. *Lithobius* lays its eggs loosely amongst earth; they are very hard to find there, and nothing is thus known of its development. The female *Geophilus* lays her eggs in heaps and watches over them; in the case of *Julus* the process is similar. Information as to the development of the Myriapoda generally is at present very imperfect. In no case as far as yet known is a blastopore formed as in *Peripatus*. The first structure to appear in *Strongylosoma* (*Polydesmidæ*) is a ventral thickened plate. The appendages are formed in succession from before backwards, and the mouth and anus as stomodæum and proctodæum. The embryo when hatched (fig. 14) has nine post-cephalic somites, the second of which is without appendages, whilst the first, third, and fourth each bear a functional pair of limbs, the fifth bears two pairs of rudimentary limbs beneath the larval skin, and the sixth a single pair, which very soon becomes double. The young *Strongylosoma* is thus provided with three pairs of functionally active legs. The young *Julus* has a similar number, the third post-cephalic somite being apodous, and it was formerly considered that this fact established a connexion between the Myriapoda and the Insecta, the three pairs of larval legs of the Myriapod being supposed to correspond with the three pairs of legs of insects. Such, however, is not the case; there being no second maxillæ in Myriapoda, the first pair of legs in the larva must correspond with the second maxillæ of insects: and even if this could be shown to be incorrect, the three pairs of legs would still not correspond with those of insects, because in the young *Strongylosoma* the second and in *Julus* the third post-cephalic somites are devoid of legs. Moreover, the larvæ are only apparently hexapodous, not in reality so. In *Pauropus* there is a hexapodous larval stage. In the Chilopoda no functional or real hexapodous larval stage occurs, as far as is known.

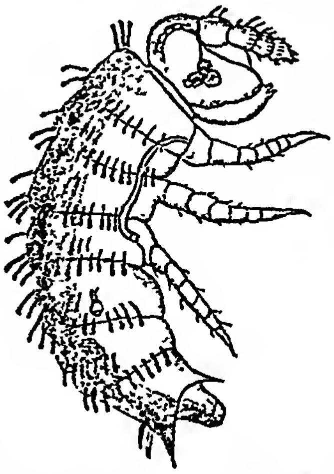

Fig. 14.—Larva of *Strongylosoma Guerinii* just hatched. (From Balfour, after Metschnikoff.)

MYRISTICA. See Nutmeg.

MYROBALANS. See Leather, vol. xiv. p. 382.

MYRON, one of the chief sculptors of the older Attic school, was born at Eleutheræ on the borders of Bœotia and Attica, and flourished in the middle of the 5th century B.C. He was, like Phidias, a pupil of Ageladas of Argos. He worked almost exclusively in bronze; the only known exception is his wooden statue of Hecate at Ægina. He made some statues of gods and heroes, but these were not the works on which his fame rested. The ancient critics, as quoted by Pliny, censured his inability to represent the feelings of the mind; hence the lofty ideals of Phidias and the Attic school in general were beyond the scope of his art. His works seemed to live and move before the spectator; but he could make an athlete hurling the discus, not a Zeus hurling the thunder. His most famous works were the Cow, the runner Ladas, and the Discobolus. Of the first, which was esteemed his greatest work, no copy is known, and, though thirty-six epigrams celebrate the realism and the life of this animal, which might be mistaken for a living cow, none of them give any information as to the attitude in which it was represented. The statue of Ladas is also unrepresented in modern museums; no imitation has yet been found. Ladas, an Argive runner, died from over-exerting himself in the long race at the Olympic games. To judge from two epigrams, Myron represented him in the moment of his supreme effort, with flanks contracted as if the last breath had gone out from them and was still hovering on the open lips. The copies that have been preserved of two other works of Myron make it easier to realize the qualities that the ancient critics praise in him. The Discobolus is known from several copies, the best being a life-size statue in the Massimi palace at Rome. The athlete is represented at the moment when, after swinging the discus (five pounds in weight) back to the full stretch of his arm, he is quickening every sinew to begin the forward motion, and to employ in delivering the discus the full strength of every muscle and the whole weight of the body and the impetus acquired by the longest possible swing of the arm.

A similar moment, the critical point when one motion is suddenly transformed into its opposite, was seized in another work, of which several copies remain. Its discovery is due to the penetration of Brunn, and, though his ingenious combination has not yet found universal acceptance, it will probably be confirmed by future discovery. He compared a relief on the Acropolis of Athens, described by Pausanias without the artist's name with the words of Pliny, (*Myron fecit*) *Satyrum admirantem tibias et Minervam*, and recognized imitations of this scene on an Attic coin, a vase-painting, and an Attic relief, in which Marsyas is represented starting back with outstretched arms before the goddess Athena. He also recognized the figure of Marsyas alone in a marble statue of the Lateran museum,

which has been restored as a dancing satyr; and a bronze statue in the British Museum has since been recognized as a slight variation of the same subject. None of these works agree completely with the words of Pausanias or with one another, but the general resemblance is so striking that they must be *free imitations of a single work*. Marsyas is surprised either by the sight of the flute which Athena has thrown away or by the threatening action of the goddess; his forward motion is suddenly checked, but he has not begun a retrograde motion. His hands, the parts which the mind commands most quickly, are thrown wide apart without any definite object in their motion, and the body is poised between the preceding action and the new action that will begin immediately. Pliny mentions a competition between Myron and Pythagoras of Rhegium, in which the Pancratiast of the latter was adjudged superior.

MYRRH is a gum-resin highly esteemed by the ancients as an unguent and perfume, used for incense in temples and also in embalming. The word is Semitic; it appears in the Old Testament as מֹר (Exod. xxx. 23; Ps. xlv. 8; Cant. *passim*), in Arabic as "morr." In Exod. (*l.c.*) "pure myrrh" should rather be "flowing myrrh," that is, the "myrrha stacte" of classical writers,—the finest myrrh, according to Pliny (xii. 35), exuding without incisions in the bark. So Johnson[1] says that it exudes from cracks in the trunk near the root and flows freely on stones underneath, the exudation being sometimes aided by bruising the bark with a stone. Myrrh was one of the gifts offered by the Magi, and a royal oblation of gold, frankincense, and myrrh is still annually presented by the queen on the feast of Epiphany in the Chapel Royal in London, this custom having been in existence certainly as early as the reign of Edward I.[2] Until the present century the botanical source of myrrh was enveloped in great obscurity. In 1826 Ehrenberg brought home specimens of the myrrh trees found at Jizán on the east side of the Red Sea, in lat. 16° 40′ N., and also on the neighbouring mountains of Jara. The more recent investigations of Hildebrandt (1878) show that one of the plants brought home by Ehrenberg and named *Balsamodendron Myrrha* yields the true myrrh. It was found by Hildebrandt growing on sunny slopes of the Sarát mountains at an elevation of 1600 to 3200 feet. It forms a low tree, attaining a height of not more than 10 to 12 feet, with thorny branches and a light grey bark, bearing some resemblance to those of the hawthorn. The leaves are ternate, the two lateral leaflets being minute in comparison with the central one; they are smooth, obovate, and denticulate. The fruit is about the size of a pea, oval and somewhat compressed. The tree grows interspersed among *Acaciæ* and *Euphorbiæ* in dwarfish thickets. The myrrh, according to Ehrenberg, when it first exudes is of an oily and then of a buttery consistence, and of a yellowish white colour, gradually assuming a golden and ultimately a reddish tinge as it hardens. Myrrh is chiefly collected, according to Vaughan,[3] in the Somali country and in the neighbourhood of Harar (9° 20′ N., 42° 17′ E.) south-west of Zeila, in the months of July and August (Johnson, *loc. cit.*), and is brought to the great fair of Berbera held in November, December, and January. Thence it is transported to Aden and shipped to Bombay, where it is sorted, the inferior kinds being sent chiefly to China and the finer sorts to Europe. The Banians of India, who trade in myrrh, have their business houses at Bombay, but employ partners or agents, who reside at Makallah and Aden to attend the fair at Berbera, and exchange Indian or English piece goods for myrrh, bdellium, and frankincense. Myrrh of the best quality is known as Turkey myrrh, and the inferior quality as East Indian myrrh, from being exported from Bombay. At the present time, however, all myrrh is imported either direct from Aden or from Bombay. The Somalis also cross over to the Arabian shore and collect this gum-resin on the hills about Shugra and Surcea to the east of Aden, where myrrh trees abound. The myrrh of this district differs slightly in appearance, and is less resinous than that of Somali Land, and in the opinion of Hanbury (*Pharm.*, p. 143) is probably the produce of a distinct species of *Balsamodendron*. The difference between African and Arabian myrrh was known to the ancients, who considered the Troglodyte or African myrrh the best. At Bombay this difference is still recognized. Specimens of the Arabian myrrh tree collected by Wykeham Perry in 1878 were less spinous than those of the Somali plant, but were too imperfect to determine if they belonged to a distinct species. *Balsamodendron Kua*, R. Br., a small spiny Abyssinian species allied to *B. Myrrha*, as yet undescribed, was found by Salt to yield myrrh.

Myrrh is usually imported in chests containing from one to two cwt., and is mixed with other gum-resins obtained from different species of *Balsamodendron*. The principal of these are subjoined.

(1) *Baisa Bol*, *Bhesa Bol*, or *Bissa Bol*, probably the produce of *Balsamodendron Kataf*, Kunth, a tree which is known to the Somalis as *hebbakhade*, and which has much larger leaves than the myrrh tree. This gum-resin resembles myrrh in appearance, but has a disagreeable taste and is scarcely bitter. At Aden bissa bol is worth only 2½ rupees per maund (28 lb), while myrrh sells for 9½ rupees per maund. It is used in China, mixed with food, to give to milch cows to improve the quality and increase the quantity of milk, and when mixed with lime as a size to impart a gloss to walls. (2) Opaque bdellium, probably identical with the gum hotai described by Vaughan (*loc. cit.*), and produced by *B. Playfairii*. When shaken with water it forms a slight but permanent lather, and on this account is used by the Somali women for cleansing their hair and by the men to whiten their shields. It is known as *meena hârma* in Bombay, and is there used for the extraction of the guinea-worm. (3) African bdellium is the produce of *B. africanum*, and is probably the tree described by Adanson as *Niottout*. The last two gum-resins are without the white streaks which are characteristic of myrrh and bissa bol; the former presents an opaque and the latter a resinous appearance, both being acrid, but having scarcely any bitterness or aroma. (4) Indian bdellium, probably identical with the Indian drug googul obtained in Scinde and Baluchistán from *Balsamodendron Mukul* and *B. pubescens*, Hook, has an acrid taste, an odour resembling cedar-wood, and softens in the hand. It is probably the produce of *B. Mukul* which has recently been found by Balfour in Socotra.

As met with in commerce true myrrh occurs in pieces of irregular size and shape, from half an inch to 2 or 3 inches in diameter, and of a reddish-brown colour. The transverse fracture has a resinous appearance with white streaks; the flavour is bitter and aromatic and the odour characteristic. It consists of a mixture of resin, gum, and essential oil in varying proportions from 23 to 44 per cent., the resin being present in good specimens to the extent of 27 per cent., and the oil from ¾ to 3 per cent. The resin appears to be a complex body, partly soluble in ether and partly in bisulphide of carbon. The gum is soluble in water and forms an adhesive mucilage. The odour of myrrh is due to the volatile oil, which is heavier than water. The bitterness is believed to be due to a glucoside, the chemical constitution of which has not been ascertained. It is obtained by treating with warm water the resin extracted by means of alcohol.

Myrrh is used in medicine at present chiefly as an auxiliary to other drugs, such as iron and aloes, in order to strengthen and modify their action. It appears to have a special action on the

mucous membrane, improving the quality of its secretions and diminishing them in quantity when excessive. When taken internally it produces a sensation of warmth extending over the whole abdomen. The appetite is increased and the digestive process much facilitated, especially in cases in which there is weakness and torpidity of the intestinal canal. As an emmenagogue it is found especially useful where pulmonary complications exist. The tincture diluted with water is used as an application to spongy gums and the aphthous sore mouth of children.

The Hebrew *lôt*, erroneously translated myrrh in Genesis xxxvii. 25; xliii. 11 (Sept. στακτή; Vulg. *stacte*), is generally identified with *ladanum* (vol. xii. p. 718), which has been used as a medicine and perfume from the earliest times.[1] and is still an article of commerce in Turkey. An excellent account of the mode of collecting it is given by Tournefort (*Voyage*, i. 79).

MYRTLE. The μύρτος of the Greeks, the *myrtus* of the Romans, and the Myrtle, *Myrtus communis*, of botanists, as now found growing wild in many parts of the Mediterranean region, doubtless all belong to one and the same species. It is a low-growing evergreen shrub, with opposite leaves, varying in dimensions, but always small, simple, dark-green, thick in texture, and studded with numerous receptacles for oil. When the leaf is held up to the light it appears as if perforated with pin-holes owing to the translucency of these oil-cysts. The fragrance of the plant depends upon the presence of this oil. Another peculiarity of the myrtle is the existence of a prominent vein running round the leaf within the margin. The flowers are borne on short stalks in the axils of the leaves. The flower-stalk is dilated at its upper end into a globose or ovoid receptacle enclosing the 2- to 4-partitioned ovary. From its margin proceed the five sepals, and within them the five rounded, spoon-shaped, spreading, white petals. The stamens spring from the receptacle within the petals and are extremely numerous, each consisting of a slender white filament and a small yellow two-lobed anther. The style surmounting the ovary is slender, terminating in a small button-like stigma. The fruit is a purplish berry, consisting of the receptacle and the ovary blended into one succulent investment enclosing very numerous minute seeds destitute of perisperm. The embryo-plant within the seed is usually curved.

In cultivation many varieties are known, dependent on variations in the size and shape of the leaves, the presence of so-called double flowers, &c. The common myrtle is the sole representative in Europe of a large genus which has its headquarters in extra-tropical South America, whilst other members are found in Australia and New Zealand. The genus *Myrtus* also gives its name to a very large natural order, the general floral structure of which is like that of the myrtle above described, but there are great differences in the nature of the fruit or seed-vessel according as it is dry or capsular, dehiscent, indehiscent, or pulpy. Minor differences exist according to the way in which the stamens are arranged. The aromatic oil to which the myrtle owes its fragrance, and its use in medicine and the arts, is a very general attribute of the order, as may be inferred from the fact that the order includes, amongst other genera, the *Eucalyptus*, the *Pimenta*, and the *Eugenia* (cloves). the boundary between the two; but on this subject also there was much discrepancy among ancient geographers.

The physical geography of Mysia (considered apart from that of the Troad) is characterized by two mountain-chains: that of Olympus in the north, which may be regarded as constituting the boundary between Mysia and Bithynia, and rises to a height of more than 6000 feet; and that of Temnus in the south, which for some distance separates Mysia from Lydia, and is afterwards prolonged through the former province to the neighbourhood of the Gulf of Adramyttium. The only considerable rivers are the Rhyndacus and its tributary the Macestus in the northern part of the province, both of which have their sources in the high tableland of Phrygia, and, after diverging widely in their course through Mysia, ultimately unite their waters below the Lake of Apollonia at a distance of only about 15 miles from the Propontis. The Caicus in the south takes its rise in Mount Temnus, and from thence flows westward to the Ægean Sea, passing within a few miles of the city of Pergamum, and discharging its waters into the Elaitic Gulf. In the northern portion of the province are two considerable lakes: that of Apollonia, formed by the expansion of the waters of the Rhyndacus, and nearly 50 miles in circumference; and that of Miletopolis, about 30 miles round, the waters of which are discharged into the Macestus.

The most important cities of Mysia were Pergamum in the valley of the Caicus, about 20 miles from the sea, which under the successors of Alexander became the seat of a flourishing Greek monarchy (see PERGAMUM), and Cyzicus on the shores of the Propontis, a Milesian colony, which attained to a high degree of wealth and prosperity. But the whole of the sea-coast from thence round to the Gulf of Adramyttium was studded with a series of Greek towns, extending along the south shore of the Propontis, as well as the Hellespont and the Troad, several of which were places of considerable importance, including Parium, Lampsacus, and Abydos. In like manner the whole sea-coast from the Gulf of Adramyttium to the mouth of the Caicus, and from thence to the Elaitic Gulf, was occupied by Greek colonies, many of them dating from a very early period, and for the most part of Æolian origin, from which circumstance the whole of this coast district was known by the name of Æolis, as the corresponding district between Lydia and the sea was called Ionia (ÆOLIS). The most considerable of these Greek towns were Assos and Adramyttium, on the gulf that derived its name from the latter city, and farther south, on the Elaitic Gulf, Elæa, Myrina, and Cyme.

Ancient writers all agree in describing the Mysians as a distinct people, like their neighbours the Lydians and Phrygians, though they never appear in history as an independent nation. Their ethnological relations, like those of the other tribes of western Asia, are rather obscure; but it appears from Herodotus and Strabo that they were a kindred race with the Lydians and Carians, a fact attested by their common participation in the sacred rites at the great temple of Zeus at Labranda, as well as by the statement of the historian Xanthus of Lydia (a competent authority upon such a point) that their language was a mixture of Lydian and Phrygian. Strabo was of opinion that they came originally from Thrace, and were a branch of the same people as the Mysians or Mæsians who dwelt on the banks of the Danube,—a view not inconsistent with the preceding, as he considered the Phrygians and Lydians also as having migrated from Europe into Asia. According to a Carian tradition reported by Herodotus (i. 171) Lydus and Mysus were brothers of Car,—an idea which also points to the belief in a common origin of the three nations. The Mysians appear in the list of the Trojan allies in

no trace of the exuberant comic power and geniality of his great contemporary. His critical spirit and vehement temper declare his affinity rather to Lucilius than to Plautus.

He was not only the oldest native dramatist, but the first author of an epic poem,—which, by combining the representation of actual contemporary history with a mythical background, may be said to have created the Roman type of epic poetry. The poem as he gave it to the world was one continuous work, and was divided into seven books by a grammarian of a later age. The earlier part of it treated of the mythical adventures of Æneas in Sicily, Carthage, and Italy, and borrowed from the interview of Zeus and Thetis in the first book of the *Iliad* the idea of the interview of Jupiter and Venus, which Virgil has made one of the cardinal passages in the *Æneid*. The later part of the poem treated of the events of the First Punic War in the style of a metrical chronicle. The few remaining fragments produce the impression of vivid and rapid narrative, to which the flow of the native Saturnian verse, in contradistinction to the weighty and complex structure of the hexameter, was naturally adapted. Mommsen has noticed that in these fragments the story is told in the present tense. The disparaging criticism of Ennius—

> "Scripsere alii rem
> Versibu' quos olim Fauni vatesque canebant, &c."—

applies to the rudeness of the verse, not to the spirit or substance of the work. Cicero speaks of it as giving pleasure, like a statue of Myron, and the grudging admission of Horace—

> "Nævius in manibus non est et mentibus hæret
> Pæne recens"—

attests the fresh pleasure with which it still could be read in the Augustan age.

The impression we get of the man is that, whether or not he actually enjoyed the full rights of Roman citizenship, he was a vigorous representative of the bold combative spirit of the ancient Roman commons,—of the political not, like Plautus, of the bourgeois type of the Roman plebeian. Energy of character and vitality of temperament are shown by the prolonged continuation of his career as a writer, notwithstanding the discouragement of his imprisonment, and, what was a greater trial than temporary imprisonment, his exile. The chief service which he rendered to Roman letters was that he was one of those who made the Latin language into a great organ of literature, and that with the new formative energy which he applied to it he transmitted the force of the best popular speech of his time. The phrases still quoted from him have nothing of an antiquated sound, while they have a genuinely idiomatic ring. As a dramatist he worked more in the spirit of Plautus than of Ennius, Pacuvius, Accius, or Terence; but the great Umbrian humorist is separated from his older contemporary, not only by his breadth of comic power, but by his general attitude of moral and political indifference. The power of Nævius was the more genuine Italian gift—the power of satiric criticism—the "Italum acetum" which was employed in making men ridiculous, not, like that of Plautus, in extracting amusement from the humours, follies, and eccentricities of life. His more truly creative faculty seems to have shown itself, not only in rapid and animated narrative, but in pregnant invention which still lives in literature, owing to the recognition of its value by the receptive and reproductive genius of Virgil. Although our means of forming a fair estimate of Nævius are more scanty than in the case of the other makers of Roman literature whose work is only known to us in fragments, yet all that we do know of him leads to the conclusion that he was far from being the least among them, and that with the loss of his writings there was lost a vein of national feeling and genius which reappears rarely in the writings of the later republican and the imperial times—the vein which probably was predominant in Cato, which may still be traced in the fragments of Lucilius and in the personal and political lampoons of Catullus, and may be detected under the rhetorical invective of Juvenal.

Collections of the *Fragments* have been made and commented on by Klussmann (1843) and Vahlen (1852). A short study of the life and writings of Nævius (*De Cn. Nævii vita et scriptis*) has been written by M. Berchem. (W. Y. S.)

NÆVUS, a term in surgery signifying that form of tumour which is almost entirely composed of enlarged blood-vessels. There are three principal varieties:—(1) the capillary nævus, consisting of enlarged capillaries, frequently of a purplish colour, hence the term "port-wine stain"; (2) the venous nævus, in which the veins are enlarged, of a bluish colour; (3) the arterial nævus, in which there is distinct pulsation, it being composed of enlarged and tortuous arteries. The nævus can be lessened in size by pressure. It is generally met with in the skin or immediately under the skin; sometimes it lies in the mouth in connexion with the mucous membrane. It is often congenital, hence the term "mother's mark," or it may appear in early childhood. It often grows rapidly, sometimes slowly, and sometimes growth is checked, and it may gradually diminish in size, losing its vascularity and becoming fibrous and non-vascular. This natural cure is followed by less deformity than a cure by artificial means. It is a good rule not to interfere unless the tumour is growing rapidly and at a rate out of proportion to the growth of the child. Various methods are used by surgeons when an operation is called for:—(1) the tumour may be excised; (2) a ligature tightly tied may be applied to the base of the tumour; (3) inflammation may be set up in the growth by the injection of irritating agents,—in this way its vascularity may be checked and the formation of fibrous tissue encouraged; (4) the blood in the enlarged vessels may be coagulated by the injection of coagulating agents or by electrolysis. In large nævi the last method is very suitable, and the resulting cure most closely resembles the natural cure already described.

NÁGA HILLS, a district in the south-eastern corner of the chief-commissionership of Assam, India, lies between 25° 13' and 26° 32' N. lat., and between 93° and 94° 13' E. long., being a mountainous borderland between Nowgong district and Manipur state, with an area of about 6400 square miles. It forms a wild expanse of forest, mountain, and stream. The valleys and hills are covered with dense jungle, dotted with small lakes and marshes. Coal is known to exist in many localities, as well as limestone, chalk, and slate. The chief rivers are the Dáyang, Dhaneswarí, and Jamuna, only navigable for small boats during the rainy season.

In 1870 the deputy-commissioner roughly estimated the strength of the different tribes as follows:—Assamese, 705; Aitaniyás, 355; Cácháris, 3505; Míkirs, 8820; Kukis, 2524; Nágás, 66,535; total, 82,444. The estimated population in 1881-82 was 93,000. Agriculture is conducted in a rude, nomadic fashion, the only implements of tillage being the *dáo* or hill knife, and a *koddli* or hoe. Rice and millet are the main crops. In some places great skill is displayed in irrigation. The tea plant is indigenous, and a large number of natives are now employed in the tea-gardens. The manufactures embrace the production of the few rude articles required for domestic use or as clothing, and the forging of *dáos*, *koddlis*, and spear-heads. Trade is generally conducted by means of barter, and has considerably increased of late years. The local products available for export comprise rice, cotton, cloth woven from nettle fibre, ivory, beeswax, and various dyes obtained from the jungle. Salt and iron are imported; but the one great desire of every Nágá is to have a gun. The revenue is nominal.

British administration was first introduced into the district in 1867; but it has not yet been surveyed, and it constitutes perhaps the least orderly portion of the Indian empire. It is inhabited by several wild aboriginal tribes, collectively known as the Nágás. Those within British territory are comparatively peaceful, but beyond the reach of British influence are several savage and predatory tribes, who are in the habit of raiding on the plains, and killing or carrying off inoffensive British subjects. Repeated expeditions have been despatched to chastise them in their native hills. In 1873 a survey party under Lieutenant Holcombe were treacherously massacred. In January 1875 a force escorting a survey party under Captain Butler was attacked by Nágás, but unsuccessfully; later in the same year, however, he was cut off and killed. In 1879-80 the Nágás murdered the deputy-commissioner, Mr Damant, and, after receiving a sharp punishment, made a foray on the Cáchár side, murdering a tea-planter and committing other ravages. For some time the district has been in a more settled condition. The construction of a road to Kohima, the principal town, and the settlement of a British governor there have produced a salutary effect. The eastern Nágás are becoming rapidly civilized.

NAGASAKI, or sometimes NANGASAKI, the leading seaport on the western coasts of Japan, is situated in 32° 44' N. lat. and 129° 52' E. long., in the island of Kiu-shiu, and gives its name to a *ken* (province of Hizen or Hi-shiu). The harbour is formed by a beautiful inlet of the sea, stretching northward for a distance of about 4 miles, with an average width of about a mile, enclosed on both sides by a delightful framework of hills (1500 feet), and adorned by a number of the most picturesque-looking islands. The city lies near the upper end of the inlet on

the wodeyar ("lord") of Mysore, who in 1610 seized the fort of Seringapatam, and so laid the foundation of the present state. His fourth successor, Chikka Deva Ráj, during a reign of thirty-four years, made his kingdom one of the most powerful in southern India. In the 18th century the famous Haidar Alí usurped the throne, and by his military prowess made himself one of the most powerful princes of India. His dynasty, however, was as brief as it was brilliant, and ended with the defeat and death of his son Tipu at Seringapatam in 1799. A representative of the ancient Hindu line was then replaced on the throne. Owing to his career of misgovernment, the British administration assumed the authority in his name in 1831. He died in 1868, leaving an adopted son, Chikka Krishna Arasu, a minor, during whose pupilage and training the state management was conducted by British officers. The full sovereignty of the state was handed over to him in March 1881.

MYSORE, the ancient capital of the above state, is situated 10 miles south-west of Seringapatam, in 12° 18′ N. lat. and 76° 41′ E. long., with a population of 60,292 in 1881. The town, which is spread over an area of about 3 square miles, lies at the foot of the Chámundi hill, in a valley formed by two parallel ridges running north and south. The streets generally are broad and regular, except in the fort. The majority of the houses are tiled, and some of them are substantial buildings two or three stories high. Altogether, the town has a clean and prosperous look, and its sanitary condition has been greatly improved of late years. The fort stands in the south of the town, forming a quarter by itself; the ground-plan is quadrangular, each of the sides being about 450 yards long. In the interior is the palace of the mahárájá, built in an extravagant style of Hindu architecture, and adorned inside with a few paintings by a European artist, the principal object of interest being the throne, which is said to have been presented to Chikka Deva Ráj by the emperor Aurangzeb. A new palace has been erected at Bangalore for the young mahárájá. Opposite the western gate of the fort is a lofty and handsome building known as the Mohan Mahál, erected by the late mahárájá for the entertainment of the European officers. The houses of the European residents are, for the most part, to the east of the town. The residency was built by Colonel Wilks in the beginning of this century. It has a handsome portico; and a room at the back, added by Sir John Malcolm, is said to be the largest in India. The building now used for the district offices was originally built by Colonel Wellesley (duke of Wellington) for his own occupation. Mysore was the capital of the state up till 1831, when on the British occupation the seat of administration was removed to Bangalore. (W. W. H.)

MYSTERIES. This name was applied to certain ceremonies in Greek religion which were esteemed peculiarly sacred and might not be freely spoken about. The subject is one of great difficulty on account of the absolute silence maintained with regard to it by many writers, and the guarded terms in which the few references to it are couched. The obligation to silence was not felt by the Christian writers, and it is to them that we owe most of our knowledge. Their testimony is of doubtful value, and it has been keenly debated whether any trust can be placed in it; but it is in such perfect accord with the few references in pagan authors that this scepticism is unjustifiable. The Christian writers on whom we have to depend were arguing against pagan opponents, and their arguments would have lost all force if it had been possible to retort that the descriptions and facts were inaccurate. The Mysteries were the chief stronghold of those pagan controversialists who maintained that all the truths and the morality advocated by the Christian writers were contained in the Greek religion, and therefore the Christians directed their arguments chiefly against this strongest part of their opponents' case. It results from a study of the evidence that, on the whole, they stated the case in favour of the Mysteries with much clearness and fairness, admitting the good points, but directing their polemic against the weak side.

Of the many Mysteries which existed in different parts of Greece, the Eleusinian were the most famous, the most widely popular, the most representative in every way. In several parts of Greece—*e.g.*, at Phlius—there were Mysteries directly adopted from Eleusis; in other places, such as Lerna, Andania, &c., a genuine old mystic cultus was greatly modified by the same example.[1] The Christian writers therefore direct their polemic mainly against the Eleusinian Mysteries, and the material for study is far less scanty in their case than in any other. The following remarks, accordingly, will be almost entirely confined to them. Any discussion of the subject must be founded on Lobeck's great work *Aglaophamus* (1829), in which, with equal learning and acuteness, he destroyed once for all the *a priori* theories current before his time, that the Mysteries enshrined a primitive revelation of divine truth made to mankind, or contained a philosophic doctrine borrowed by the Greeks from the wisdom of the East and handed down unmodified from generation to generation.[2] As a constructive work, Lobeck's treatise is not so perfect. What we are in search of is not so much the objective facts of the Mysteries as the place which they held in the Greek mind. The effect of a religious institution like the Mysteries depends chiefly on subjective considerations; actions and rites in themselves quite commonplace may bear to the eye of faith the most sacred and impressive character. This point of view is not taken into account by Lobeck. Again, the polemical character detracts from the value of his work as a final statement of the question; he is sometimes satisfied with proving that ancient evidence does not bear out the theories which he combats, but he does not estimate duly its actual worth. Finally, additional evidence has been accumulated since his time; inscriptions and works of art have afforded important corroborative evidence, and it is certain that statements which Lobeck set aside as not referring to the Eleusinian religion do really relate to it.[3]

There is no ancient authority to show that the ritual of the Mysteries differed essentially from that of the general religion of Greece. All ancient testimony tends to prove that the ritual was based on religious myths, similar to those which were common in Greece, and that the difference between mystic and exoteric rites lay chiefly in the accompaniments. Athenæus[4] says that the Mysteries were distinguished from the ordinary festivals by their peculiar magnificence and expense, and by the "mystic paradosis" which took place at them, *i.e.*, certain sacred things were exposed in a peculiarly impressive manner to the worship of the participants. Their magnificence must have been very great. Painting, sculpture,

[1] The contrast between the account given by Pausanias of the Mysteries of Andania in the 2d century after Christ and the account given in the great inscription 91 B.C. shows how the example of Eleusis had worked in the interval.

[2] The chief older theories of the Mysteries were those of Warburton, St Croix, and Creuzer.

[3] The principal special authorities on the Mysteries since Lobeck are:—Sauppe, *Mysterieninschr. von Andania*; Foucart's commentary on this inscription in Le Bas, *Voyage Archéol.* (1847-77), *Inscr. de la Peloponn.*; Foucart, "Inscr. d'Eleus." in *Bull. [4] Athen., ii. p. 40 D.

architecture, music, dancing, &c., were combined with lavish skill to form one grand and impressive spectacle. Other great festivals were displays of Attic splendour, but the Mysteries were intended, in the Periclean scheme, to be the great religious ceremony of all Greece; the allies were required, and the other Greeks requested, to pay homage and first-fruits to the two goddesses of Eleusis.[1]

The strictest secrecy was enjoined and observed in regard to the Mysteries and everything connected with them; but this secrecy was not that of a narrow cult, confined to a small number of participants. The Eleusinian Mysteries were open as early as the time of Herodotus to any of the Greeks who wished to be initiated.[2] There was, therefore, no secret to keep inviolate from the uninitiated. Just as in the actual representation of the Mysteries a silence so strict as to be proverbial[3] was maintained, so it was a condition of their good effect that they should not hereafter be lightly spoken of.[4] Those who believed in the Mysteries kept in their heart, as a saving and sacred possession, the knowledge of what they had seen and heard and kissed and handled; the thought was too holy to be rashly spoken of, even to the initiated.[5] Numerous references prove that this mystic silence was generally very carefully observed. In the poets we sometimes find an affectation of observing silence about myths which are quite common property; and writers of religious or superstitious character frequently make a mystic secret of matters that less scrupulous writers speak freely about.[6] The degree to which silence was observed depended entirely on the individual conscience, and the fact that it was in general so strictly maintained is the best proof of the vitality and power of the Mysteries over the popular mind.

The saving and healthy effect of the Eleusinian Mysteries was believed in not only by the mass of the people but by many of the most thoughtful and educated intellects, Pindar, Sophocles, Isocrates, Plutarch, &c.[7] Plato, who finds no language too strong to stigmatize the demoralizing effect of the Orphic Mysteries, speaks of the Eleusinia with great respect; he compares the contemplation of the "ideas" by the disembodied souls to the contemplation of the "phasmata"[8] revealed in the Mysteries. This saving power is expressly connected with the future life; he that has been initiated has learned what will ensure his happiness hereafter. This point, which is ridiculed by Lobeck (pp. 70-1), must be examined carefully. The words of Pindar, Sophocles, Isocrates agree with the words of the Homeric *Hymn* (l. 480) that the initiated have peculiar advantages in the future world, and many other passages are equally clear and distinct. Lobeck maintains that they have no special meaning, inasmuch as Isocrates says the same about all men who live an upright life.[9] This argument misses the most important religious question with regard to the subject,—Is the salvation in the future life, which is assured by initiation, attained by mere ritualistic observances, or does it depend on the effect produced by initiation on the life and character of the initiated person? Plato condemns in the strongest terms the Orphic Mysteries, which promise salvation in return for mere ritualistic acts of purification and initiation; if he respects the Eleusinian Mysteries, which also promise salvation as the reward of initiation, this can be only because he believes that they promise it on different grounds. The reason is explained by Isocrates, who expressly says that this salvation in the future life, the reward of the initiated, is gained by all who live a pious and just life. In like manner, Diodorus says that the initiated are said to grow better; and Andocides makes a similar remark about the object of the Mysteries. According to Sopater, initiation establishes a kinship of the soul with the divine nature; and Theon Smyrnæus says that the final stage of initiation is the state of bliss and divine favour which results from it.[10]

These quotations prove the general belief that the aim of the Eleusinian Mysteries was high, and that a lasting effect was produced by them on the initiated. This implies a high stage of religious thought, such as no other ancient faith, except that of the Hebrews, attained; but a passage in a Rhodian inscription of the 5th century B.C. shows that this idea was not wholly unfamiliar in Greek religion. The first and most important condition required of those who would enter the temple at Lindus is that they be pure in heart, and not conscious of any crime; conditions of ceremonial purity are enumerated as secondary matters.[11] Now, with regard to the profanation of the Mysteries by those persons who ridiculed them, it is easy to understand that the very simple character of the rites, the commonplace nature of the sacred things which were exposed as the crowning ceremony of the Mysteries to the adoration of the people, lent themselves readily to ridicule when contrasted with the solemn preparations that led up to the crowning act, and the great effects that were expected from the initiation. The people who had been initiated, who believed in the salutary effect of the admission to handle and kiss the sacred objects, were naturally both shocked and indignant at the ridicule thus cast on their holy sacrament by the pitiless analysis of a cold disbelieving intellect. They felt that more than met the eye existed in these sacred things. The Mysteries occupied a place among the ancients analogous to that of the Holy Sacrament in the Christian church. The intention was to admit all that were not notoriously wicked; the disqualifying crime was unexpiated murder. The belief was entertained that the solemnity and impressiveness of the ceremony tended to produce a strong effect on the character of the initiated.

There is overwhelming proof in ancient writers that the effect of the Mysteries was not dependent on any dogmatic instruction. Even the doctrine of a future life, which is always associated in the old writers with the Mysteries, was not expressly inculcated in them, but left to the spectators to gather for themselves from the spectacle presented to them.[12] On the other hand, ancient testimony shows a striking unanimity in describing the manner in which the Mysteries were believed to educate the people. One of the most important passages is that where Galen maintains that the study of nature, if prosecuted with the concentrated attention given to the Mysteries, is even more fitted than they are to reveal the power and wisdom of God, inasmuch as these truths are more obscurely expressed in the Mysteries than in nature. Plato compares the contemplation of the "ideas" with that of the Mysteries; Chrysippus calls the discussion on the nature of the gods, which forms the last section of the Stoic physic, τελετή.[13] From

these passages we may infer the belief of the writers that important truths were enigmatically[1] expressed in the Mysteries, and that the intellect which could penetrate beneath the surface was able to apprehend them. Plutarch says that it required a philosophic training and a reverent religious frame of mind to comprehend the Mysteries. Similarly Aristotle expressly says that no instruction was given to the *μύσται*, but that, while in a suitable state of receptivity, their emotions and character were acted upon. The testimony of the Christian writers is entirely to the same effect; while stigmatizing the impure character of some of the rites, they always admit that the Mysteries were intended to lead the people up to a knowledge of religious truth.[2] It is obvious that the essential point on which the effect of the ceremony depended was that the mind of the initiated should be wrought up to a pitch of eager, rapt expectancy and breathless attention. The attentive silence of the spectators at the Mysteries was proverbial. Many means contributed to produce this state. A certain amount of previous training and instruction was imparted by the *μυσταγωγοί* to the candidates. It is true that all who had been initiated had the right to act as *μυσταγωγοί*, that they were left legally free to introduce any one whom they thought fit, that the amount of instruction they could impart varied according to their character and education. Lobeck has emphasized all these elements which tended to impair the character and lessen the effect of the Mysteries. But though this point is incapable of proof, the general character of the Mysteries suggests that custom may have modified to some degree the freedom allowed by law, and that the Eleusinian officials tried to regulate the instruction given. Moreover, the lesser Mysteries were a kind of preparation for the greater, and Clement mentions that in them, and in them alone, a certain amount of instruction was given to the *μύσται*.[3] These circumstances combined with the general belief of the people in the holiness and power of the Mysteries to produce in the mind of the *μύσται* an expectant feeling and a disposition to look for some meaning in the spectacle.

The grades of admission to the Mysteries tended to produce the same impression. The process of initiation was not a momentary one, completed in one act; it extended over an elaborate series of stages, and the ancients certainly associated these successive steps with a gradual increase of knowledge and insight. The candidate was initiated in the lesser Mysteries in Anthesterion (February) at Athens; he was admitted as a *μύστης* at Eleusis in the following Boedromion (September), but he could not attain the higher initiation as *ἐπόπτης* till at least one year more had elapsed. It was also believed that a higher order of initiation was reserved for those who were qualified for the offices of *ἱεροφάντης* and *δᾳδοῦχος*, in which the last knowledge of the cultus was imparted to them.[4]

Finally, the physical circumstances of the initiation were such as to produce an excited and high-strung nervous condition. The nine days' fast, very strictly observed,[5] the long march from Athens to Eleusis and the frequent religious ceremonies with which it was marked, the wandering by night around the shores and plain of Eleusis with torches in search of the lost Cora,—all tended to produce a strained enthusiastic state. And the season of the year and of the month—for the nights were dark—co-operated; Boedromion fell about the end of the hot season, when the bodily strength is usually low. Then came the actual Mysteries: the *μύσται* were admitted to the holy building; the splendid illumination seemed dazzlingly bright after the darkness outside; the strange apparitions, the impressive voices, the gorgeous dresses of the actors, the magnificence of the sacred drama, to which the highly suggestive and symbolic art of Greece no doubt contributed largely,—all these they saw and heard in awestruck silence. Then came the crowning act of the ceremony: they had perhaps before this drunk the sacred draught with which the goddess had refreshed herself after her long fast, but now the holy things which the goddess had herself shown to the daughters of Celeus were revealed to them. They were admitted one by one to touch, to kiss the holy things, to lift them from the cist, to put them into the basket, to taste them, to replace them in the cist, and to pronounce the sacred formula. The scene that takes place in every modern Greek church on the eve of Easter Sunday gives some faint idea of the character of this *παράδοσις*.

This state of enthusiasm was common to all Mysteries, especially to the Phrygian. It was susceptible of great abuses, *e.g.*, the self-mutilation and the immorality of the Phrygian rites. But the spirit of Hellenism toned down the excesses, while it tried to preserve the fervour and self-forgetfulness of the Phrygian and Bacchic orgies. The relation of the state to the Mysteries contributed to regulate the excited fervour of the celebrants. While it never interfered with the established ritual, the state was the last judge in cases of misdemeanour; it appointed officials to control the expenditure and conduct the public part of the ceremony. Inscriptions[6] have thrown much light on this point, but it is not possible here to dwell on it. The Mysteries of Eleusis were the one great attempt made by the Hellenic genius to construct for itself a religion that should keep pace with the growth of thought and civilization in Greece. The strained enthusiasm attendant upon them seems at first strange and unhellenic to a mind accustomed to the moderated chastened tone of Greek art and literature, and to the spectacular character of Greek exoteric religion with its utter want of vitality and religious fervour. The public religion either became, like the Panathenaia, a purely political display of the power and splendour of Athens, or else, like much of the old ceremonial of the acropolis, was performed perfunctorily. It had no hold on the mind of the people; its simple antique ceremonies told nothing of the subjects which troubled men's minds, the thoughts of sin, of a future life, and of punishment for guilt. But the Mysteries concerned themselves precisely with these subjects: they provided a series of preliminary purifications for their votaries; they turned men's minds to the deeper problems of life and death, and gave them new views; they made some attempt to reach and touch the individual mind. Thus, while the public Hellenic religion sank into disrepute, the Mysteries became more and more important as time elapsed.

It is impossible to reconstruct the mystic ceremonial, but sufficient indications are given for us to understand its general character. It consisted of acts and words, *δρώμενα* and *λεγόμενα*, which supplemented one another, and were both required to make an intelligible whole.[7]

[1] The word "enigma" is used by Sopater, *Diær. Zetem.*, p. 120; Clem. Alex., *Strom.*, p. 658, and Christian writers frequently; Lobeck, pp. 143, 189.

[2] Plut., *Isid.*, lxviii.; Aristot. ap. Synes., *Or.*, p. 48 (ed. Petav.); Cic., *N. D.*, i. 42, is important, *rerum magis natura cognoscitur quam deorum*.

[3] Cl. Alex., *Strom.*, v. 689; Lobeck, p. 140.

[4] Theon Smyrn., *Mathem.*, i. p. 18, quoted by Lobeck, p. 39.

[5] It is nowhere mentioned that the *μύσται* fasted nine days, but the analogy of the nine days' fast of Demeter makes it quite safe to assume that this was the rule for her worshippers; see *Hymn*, l. 47-9. The fast was perhaps, like the Mohammedan Ramadan, observed only while the sun was up; but, in addition to this, various kinds of food were wholly prohibited, see Lobeck, pp. 189-91.

[6] See the inscription of Andania, and the important inscription of Eleusis published in *Bull. Corr. Hell.*, 1880.

[7] The case of the young man in Sopater's imaginary trial proves this very clearly.

The *λεγόμενα* were obscurely-worded phrases and traditional songs, whose sanctity was due to their antiquity. They had no didactic character, and were hardly intelligible without preparatory instruction. They were chanted by the hierophant, and that a fine voice was one of the requisites for this office several epigrams and inscriptions bear witness. The mythic ancestor of the family, in whom are embodied the requirements for the office, was called Eumolpus. The *δρώμενα* appear to have been a dramatic representation of the life of the deities by whom the Mysteries had been instituted. These deities were presented on the stage in appropriate dresses, the parts being played by the ministers of the cultus. At Andania this is known to have been the case,[1] and Porphyry enumerates the parts played by the chief officials of Eleusis at one point in the mystic drama.[2] It is also certain that figures, probably of great size, were introduced by machinery. The terms *δείγματα ἅγια, εὐδαίμονα, θεῖα, ἄρρητα*, are applied to the mystic sights.[3]

The Homeric *Hymn* to Demeter is a religious, not an historical myth. It does not relate the origin of agriculture, for the gift with which the goddess rewards her Eleusinian hosts is not the art of agriculture but the knowledge of the Mysteries (l. 273, 474). It springs directly from the cultus of Eleusis, and contains the *ἱερὸς λόγος*, the fortunes of the two goddesses, mother and daughter, the periodical representation of which formed the basis of the ritual. It is, of course, not a complete description of the ritual; it is an exoteric and poetic statement, in which the most holy of the rites and the most mysterious of the personages are alluded to only in an indirect way. The express statement of Clement,[4] that the whole myth of Cora was represented at Eleusis, confirms the inference drawn from the *Hymn*. Many writers[5] refer to the appearance presented by the shores and bay of Eleusis on the *dies lampadum*, when the worshippers wandered in the darkness with torches searching for the lost Cora. This ceremony took place in the open country, and was therefore not a part of the mystic ritual revealed to the *μύσται* in the *τελεστήριον*. It probably took place on Boedromion 21, on the night before the mystic rites proper began. The *μύσται* waited outside the sacred enclosure in perfect darkness on the moonless eve of Boedromion 22. Suddenly the *προπύλαια* were thrown open, and the light was seen streaming through the *ὀπαῖον* in the roof of the *τελεστήριον* and through the open door in which stood the *δᾳδοῦχος* holding up the sacred torches. This scene is frequently alluded to.[6] The scenes inside the *τελεστήριον* are mentioned less frequently,[7] but the few references point to episodes in the myth of Demeter and Cora. The hymn refers in guarded terms to the *παράδοσις τῶν ἱερῶν*, the central act of the mystic ritual. Clement enumerates the simple objects that were displayed, and gives the formula in which each *μύστης* replied as he received from the hierophant the holy objects: "I have fasted, and I have drunk the *κυκεών*; I have taken from the *κίστη*; after tasting I have deposited in the *κάλαθος*, and from the *κάλαθος* in the *κίστη*."[8] In these words he professed that he had fulfilled the sacred duties.

This whole myth bears most evidently the character of having been acted continuously at one time. It could not have been divided without losing its power over the attention and emotions of the *μύσται*. But it seems almost certain that there were two nights of mystic ceremonial, 22 and 23 Boedromion.[9] It is probable, therefore, that another play with a distinct subject was acted on one of these nights, and as the play just described is certainly the original and central point in the Eleusinian ritual, it was probably acted on the first night. Again, it is certain that there was a distinction between *μύσται* and *ἐπόπται* at Eleusis. As the *μύσται* were not admitted to witness the ritual of *ἐποψις*, it is highly probable that the second night was devoted to the higher ceremonial. It would be exceedingly difficult to effect a change in the middle of the night from the *μύησις* to the *ἐποψις*, and the good order and regularity for which the Eleusinia were famed could hardly have been maintained. The *Hymn* refers in covert terms to the holy child Iacchus, to his death and resurrection (262-4). There seems no place for Iacchus in the ritual as yet described. It is therefore a plausible conjecture that the *ἐποψις* was devoted more especially to the mystic child; and further examination will make this conjecture almost a certainty.

The development of the Eleusinian religion is a matter of speculation, but cannot be wholly passed over. Several elements must be distinguished.

1. Demeter always represents the productive and nourishing power of the earth. (*a*) In the simplest form of her cultus the act by which the earth-goddess is fertilized is conceived as an outrage and a deed of violence. The goddess, enraged, hides herself in a cave; winter and death reign in the world. At last she is appeased: she bathes in the sacred stream; her child is born, and the life of spring blooms on the earth. This cultus is most distinctly seen in Arcadia. (*b*) The worship of Demeter Thesmophorus is the religion of a more educated race: the goddess is the giver of all law, especially of the law of marriage, on which all society is founded. The worship of Demeter Thesmophorus is restricted more or less completely to women. It appears to have been the national religion of the Cadmeones, and the house of Cadmus at Thebes was the first temple of the goddess; but it spread early into Attica. The Argolic Demeter is very similar, but her cultus has been affected by Eleusinian influence. The Thesmophoric rites are so obscure that no sure idea can be gained of the relation between them and the simpler Arcadian cultus. The anger of Demeter Achea or Achaia formed part of them, and the ritual has, as A. Mommsen observes,[10] an Oriental character of vehement mourning; but we know not how the wrath of the goddess was kindled and allayed, how the alternation of winter and summer was conceived. (*c*) Eleusis was apparently the original seat of a modified form of this cultus, in which Demeter was associated with Cora. The modification perhaps arose through the fusion of the religions of two races which united in the fertile Eleusinian plain.

2. The marriage of Cora is a form of the widespread idea that the marriage of the god and goddess each spring is the pledge and cause of the fertility of earth. The "holy marriage" was celebrated in Samos, Argos, &c., with the rites of an earthly marriage, and vestiges of the primitive custom of marriage by capture can be traced in the ceremony. According to the *ἱερὸς λόγος* of Eleusis, the rape of Cora takes place in the spring (*Hymn*, l. 6, 425): it is the holy marriage by capture. But the Eleusinian myth is marked as composite and not original by an important fact; it does not explain the vicissitude of winter and summer. The abduction takes place once in the spring; winter arises from the anger of Demeter; but ever afterwards Cora goes to her husband in the autumn with her mother's consent and returns in the spring. The myth has ceased to be closely and obviously connected with the life of nature. The two cults each lost something when they were amalgamated. The annual Theogamia, a central point in the original worship of Cora,[11] becomes a mere disagreeable episode in the life of the two

[11] At Nysa, Cyzicus, and elsewhere.

goddesses. Demeter ceases to be directly connected with the life of the year, and affects it only through the fortunes of her daughter. It is an important point that the vehement *self-forgetting* enthusiasm characterizing devotees who feel their complete dependence on their deities can be traced from the beginning in the worship of the mother of all earthly life. This enthusiasm was increased by the next stage in the development of the Mysteries, the fusion of the cults of Demeter-Persephone and of Dionysus. It is uncertain how and when this fusion began: it is certain that it was not completed till after the union of Eleusis and Athens.

3. The worship of Dionysus can be traced in two phases. The cultus of the wine-god with simple rural character, rude and gross symbolism, was the religion of uneducated peasants, its chief seat being in the borderland of Attica and Bœotia. Another form of the religion of Dionysus with its orgiastic enthusiasm and its mystic character penetrated into Greece from Thrace, was accepted at Delphi alongside of the Apolline worship,[1] and established itself at Eleutheræ and on Mount Parnassus, where the women of Phocis and Attica united in the rites and revels of the god every second winter. The Dionysus of Eleutheræ was carried to Athens when the places were united, and the worship of Dionysus Eleuthereus was one of the most splendid and most impressive in the state; under its shelter grew the Attic drama.

The unification of the Attic land required as its pledge and completion the unification of the Attic religion. A common religion bound together every association in Greece; a people united politically, yet divided *religiously*, was an *unintelligible* idea to the ancient mind. When, through the decay of the Megarian power, the Eleusinian valley was incorporated in the Attic state, the worship of the Eleusinian goddess was established under the Athenian acropolis, and the whole land united in her worship. Eleusis always occupied a peculiarly independent position in Attica; it retained its own cultus in its own hands, and it had, like Salamis, the right of issuing coins.[2] It seems to have been only at a late date that the religious fusion was completed, and the relation between the Eleusinian and Attic religions was conceived in a very different style from the crude fictions by which at an earlier time Poseidon and Apollo had been incorporated in the Attic state religion.[3] The political and religious system which produced peace among the warring sections of the Attic people was due to Solon. His friendship with the mystic Epimenides, *an historical fact encrusted with much legend*, shows the tone in which the religious part of the task was executed. But the work of Solon would not have proved efficient if it had done more than formulate and legalize *the actual tendencies of the country. Especially in religion the system was growing before Solon and continued to grow after him. To this period—i.e.*, the 6th century B.C.—and to the spirit of mysticism which was so strong in Attica and in Greece generally at this *time we must* attribute the final moulding of the Eleusinian ritual.

According to the mystic theory, *the multitude of deities* are merely forms of the ultimate single divine nature dividing itself into male and female *to become the origin of life* on the earth. This theory was that *of the Orphic theology*, and many facts show that the Orphic theology moulded the Eleusinian *ritual. Dionysus*, under the mystic name Iacchus, was identified with the son of Demeter, Plutus, the prosperity that *she bestows on the world.* Eleusis and Athens were united in one mystic ritual, part of which was performed in Athens, part on the road *from* Athens to Eleusis, and the most important rites in Eleusis. The process by which the shrines along the Sacred Way became *connected* with the religion of Demeter and Iacchus was doubtless gradual; but the outlines of the system were *certainly complete before the* battle

and Persephone, which Æschylus makes, was *probably taught* at Eleusis (*Hymn*, l. 440).

If material existed to study the ritual of the shrines along the Sacred Way, we should find abundant examples of the working of the mystic system. Pausanias tells that the cultus of Apollo in the pass of Dafni grew *into a worship of* Demeter, Cora, Athena, and Apollo. Again, in reference to the worship of the hero Cyamites on the Sacred Way, he says that those who have been initiated at Eleusis, or who have read the Orphic books, will understand his religious silence. The same writer[5] mentions that Orphic hymns were used in the Eleusinian ritual, and Preller has conclusively proved the *great influence exerted* by Orphic teaching at Eleusis. Through this close connexion of Orphism with the Eleusinian Mysteries, we understand how, when the family of the Dadouchi died out in the 4th century B.C., the office was not filled up from the closely related *family of the Ceryces, but given to the* Lycomidæ, who held in their hands the Orphizing mystic cultus of Phlya. If there had not been a great similarity between the ritual of Eleusis and of Phlya, it is inconceivable that the high office of δᾳδοῦχος should have been given to a family unconnected with Eleusis. It is easy to trace the same mystic tendency in later time. In the Alexandrine period it was usual to identify Isis with Demeter, and even to maintain that the Eleusinian Mysteries were derived from Egypt. In later times the Neo-Platonic philosophy acquired influence at Eleusis, and hence we find that, according to Porphyry, the hierophant represented the "demiurgos."

There is every reason to believe that the Bacchic rites can be traced through Thrace to Phrygian influence, and that the spirit of Orphism was that of the Oriental Phrygian cultus. Moreover, the most holy and perfect rite in the Eleusinian Mysteries was to show an ear of corn mowed down in silence,[6] and this was a symbol of the Phrygian Atys. Now Clement describes in *great detail* a mystic ceremony, some parts of which he attributes to Phrygia, though the general tone of the passage rather refers it to Eleusis; some of the grossest details of this ceremony are expressly referred to Eleusis by other Christian writers.[7] These facts lead to the belief—(1) that Clement purposely mixes up two ceremonies which were similar to one another, Phrygian and Eleusinian Mysteries; (2) that this scene was acted at Eleusis on the eve of Boedr. 23; (3) that it was introduced under the influence of the Orphic mystic philosophy. *Knowing that the Phrygian rites were decried by many who praised the* Eleusinian, Clement delights to emphasize points of resemblance between them. The details given in the long account of Clement fully justify the invectives of the Christian writers. It is, however, *easy* to understand the answer that the Neo-Platonic philosophers *who admired the* Mysteries would make to their assailants. Religion places men face to face with the actual facts of life; when the mind is exalted and ennobled by intense religious enthusiasm it is able to look with pure insight at phenomena of life in which the vulgar unpurified mind sees nothing but gross materialism. The *language of religion* is plainer and more direct than the language of common life. Those who distinguished between the character of the Eleusinian and Phrygian rites might say that the same symbolism *can* be looked at with gross eyes or with idealized eyes, and might *quote the contrast* between the Aphrodite of Praxiteles and its rude *Phœnician prototype*; *the attitude*, the position of the hands is the same, but the whole meaning is changed.

It is unnecessary to enter into the question whether the Mysteries go back to a primitive "Pelasgic" religion, or are borrowed from Oriental religion. All that gives elevation and ideality to them was added by the Hellenic genius. But that spirit of enthusiastic self-abandonment which made the μύσται forget themselves in the divine nature never belonged to the true Hellenic temperament; the Mysteries were an attempt of the Hellenic genius to take into its service the spirit of Oriental religion.

It is impossible here to speak of the other Mysteries; subjects of similar nature are referred to under MITHRAS, ORPHEUS, PHRYGIA. The Eleusinian Mysteries were the most perfect example of the type in Greece; but our scanty information leads to the belief that all Hellenic Mysteries tried more or less successfully to attain the same results. Those non-Hellenic Mysteries which found their way into Greece from the 5th century B.C. onwards are of course excluded from this statement.[8]

(W. M. RA.)

MYSTERY, or MIRACLE PLAY. See DRAMA, vol. vii. p. 413.

MYSTICISM is a phase of thought, or rather perhaps of feeling, which from its very nature is hardly susceptible of exact definition. It appears in connexion with the endeavour of the human mind to grasp the divine essence or the ultimate reality of things, and to enjoy the blessed-

[5] Paus., i. 14; ix. 27.

ness of actual communion with the Highest. The first is the philosophic side of mysticism; the second, its religious side. The first effort is theoretical or speculative; the second, practical. The thought that is most intensely present with the mystic is that of a supreme, all-pervading, and indwelling power, in whom all things are one. Hence the speculative utterances of mysticism are always more or less pantheistic in character. On the practical side, mysticism maintains the possibility of direct intercourse with this Being of beings—intercourse, not through any external media such as an historical revelation, oracles, answers to prayer, and the like, but by a species of ecstatic transfusion or identification, in which the individual becomes in very truth "partaker of the divine nature." God ceases to be an object to him and becomes an experience. In the writings of the mystics, ingenuity exhausts itself in the invention of phrases to express the closeness of this union. Mysticism differs, therefore, from ordinary pantheism in that its inmost motive is religious. Pantheism, considered merely as such, may be either an elevating or a degrading theory; it expresses merely the resolution of all things into one metaphysical power or substance. But the mystic is animated not merely by the desire of intellectual harmony; he seeks the deepest ground of his own being, in order that he may cast aside whatever separates him from the true life. This religious impulse is shown in the fact that, whereas pantheism, as such, seems to lead logically to passive acquiescence in things as they are—all things being already as divine as it is their nature to be—mysticism, on the contrary, is penetrated by the thought of alienation from the divine. Even where it preaches most our essential unity with God, its constant and often painful effort is directed towards overcoming an admitted alienation. In other words, the identity with God which it teaches is not a mere natural identity, as in ordinary pantheism, but one which is the goal of achievement.

Meaning and characteristics.

These considerations do not serve, however, to differentiate mysticism sufficiently from the general course of religious thought. Alienation from, and yet implicit oneness with, the divine are the two poles on which all religious speculation and practice revolve. It follows from the above that mysticism is distinguished from other religious theories of the relation of man to God by the intensity with which it realizes the divine factor in the relation. The realization is so vivid that, though the theory takes its rise in the needs of the individual, the individual tends in the sequel to be lost altogether in the excess of the divine light. All relations tend to become unreal for the mystic except that between himself and God; his very sense of personality is weakened. The mystical ideal, therefore, is not a life of ethical energy among mankind; it is the eye turned wholly inwards, the life spent in contemplation and devout communion. The type of character to which mysticism is allied is passive, sensuous, and feminine, rather than independent, masculine, and ethically vigorous. In full-blown mysticism the individual may be said to be deprived of the rights which belong to him as an ethical personality.

The speculative bias, it will be seen, is much stronger in the mystic than in the generality of religious persons; and his speculative insight, it may be added, is usually much finer than theirs. The ordinary man, in religious matters as in others, constantly speaks of the infinite in such a way as virtually to make it finite. As Spinoza says, he passes confidently from finite to infinite and contrariwise, but never attempts to bring the two ideas together. Now mysticism does bring them together, but unfortunately in such a way as to paralyse the individual for action. Ultimately stated, the explanation of this result is to be found in the mistaken categories under which the relation is conceived. The conception of a universal substance or ground of things is naturally the first resort of the mind awakened to speculation; and it is a form which constantly recurs when men are roused afresh to philosophical activity. Nevertheless, the conception is evidently rude. It expresses properly a relation existing between material things in space; and, when applied elsewhere, is necessarily inadequate, analogical, metaphorical. But it is characteristic of mysticism that it does not distinguish between what is metaphorical and what is susceptible of a literal interpretation. Hence it is prone to treat a relation of ethical harmony as if it were one of substantial identity, or chemical fusion; and, taking the sensuous language of religious feeling literally, it bids the individual aim at nothing less than an interpenetration of essence. And, as this goal is unattainable while reason and the consciousness of self remain, the mystic begins to consider these as impediments to be cast aside. Our consciousness of self is the condition under which we possess a world to know and to enjoy; but it likewise isolates us from all the world beside. Reason is the revealer of nature and of God; but, by its very act, reason seems to separate the things reasoned about. Hence mysticism demands a faculty above reason, by which the subject shall be placed in immediate and complete union with the object of his desire,—a union in which the consciousness of self has disappeared, and in which, therefore, subject and object are one. This is the intuition or ecstasy or mystical swoon which appears alike among the Hindus, the Neo-Platonists, and the mediæval saints. And here it will be observed that the original acceptance of metaphor as speculative truth has terribly avenged itself; for, with the renunciation of self-conscious reason, the divine has been degraded into an object of sense, and its highest realization has come to be placed either in a state of brutish torpor or in a moment of equally unnatural nervous excitation. Not that mysticism always appears in this extreme form, but such is the goal towards which it constantly tends. If the sensuous metaphors of unsophisticated religious feeling be put forward as a metaphysical theory of the supersensuous, it is only to be expected that the practice deduced from such a theory will be a sophisticated or morbid development of sense, a strain put upon the bodily organs to make them yield a realization of the theory and achieve what is impossible to the sane and conscious reason. The morbid play of the nerves is objectified by the over-driven brain and treated as a sensuous union of the created with the creative spirit, an actual seeing, nay, tasting, of the divine essence.

To sum up, then, we may say that, compared with pantheism, mysticism is dependent upon a specifically religious impulse; but, whereas religion is ordinarily occupied with a practical problem and develops its theory in an ethical reference, mysticism displays a predominatingly speculative bent, starting from the divine nature rather than from man and his surroundings, taking the symbolism of religious feeling as literally or metaphysically true, and straining after the present realization of an ineffable union. The union which sound religious teaching represents as realized in the submission of the will and the ethical harmony of the whole life is then reduced to a passive experience, to something which comes and goes in time, and which may be of only momentary duration.

From these general remarks it will be sufficiently apparent that mysticism is not a name applicable to any particular system. It may be the outgrowth of many differing modes of thought and feeling. Most frequently it appears historically, in relation to some definite system of belief, as a reaction of the spirit against the letter. When a religion begins to ossify into a system of formulas and observances, those who protest in the name of heart-religion are not unfrequently known by the name of mystics. At times they merely bring into prominence again the ever-

fresh fact of personal religious experience; at other times mysticism develops itself as a powerful solvent of definite dogmas.

A review of the historical appearances of mysticism will serve to show how far the above characteristics are to be found, separately or in combination, in its different phases.

Eastern Systems. In the East, mysticism is not so much a specific phenomenon as a natural deduction from the dominant philosophic systems, and the normal expression of religious feeling in the lands in which it appears. Brahmanic pantheism and Buddhistic nihilism alike teach the unreality of the seeming world, and preach mystical absorption as the highest goal; in both, the sense of the worth of human personality is lost. India consequently has always been the fertile mother of practical mystics and devotees. The climate itself encourages to passivity, and the very luxuriance of vegetable and animal life tends to blunt the feeling of the value of life. Silent contemplation and the total deadening of consciousness by perseverance for years in unnatural attitudes are among the commonest forms assumed by this mystical asceticism. But the most revolting methods of self-torture and self-destruction are also practised as a means of rising in sanctity. The sense of sin can hardly be said to enter into these exercises; that is, they are not undertaken as penance for personal transgression. They are a despite done to the principle of individual or separate existence.

The so-called mysticism of the Persian Sufis is less intense and practical, more airy and literary in character. Sufism (probably derived from σοφός) appears in the 9th century among the Mohammedans of Persia as a kind of reaction against the rigid monotheism and formalism of Islam (see MOHAMMEDANISM, vol. xvi. p. 594). It is doubtless to be regarded as a revival of ancient habits of thought and feeling among a people who had adopted the Koran, not by affinity, but by compulsion. Persian literature after that date, and especially Persian poetry, is full of an ardent natural pantheism, in which a mystic apprehension of the unity and divinity of all things heightens the delight in natural and in human beauty. Such is the poetry of Hafiz and Saadi, whose verses are chiefly devoted to the praises of wine and women. Even the most licentious of these have been fitted by Mohammedan theologians with a mystical interpretation. The delights of love are made to stand for the raptures of union with the divine, the tavern symbolizes an oratory, and intoxication is the bewilderment of sense before the surpassing vision. Very often, if not most frequently, it cannot be doubted that the occult religious significance depends on an artificial exegesis; but there are also poems of Hafiz, Saadi, and other writers, religious in their first intention. These are unequivocally pantheistic in tone, and the desire of the soul to escape and rest with God is expressed with all the fervour of Eastern poetry. This speculative mood, in which nature and beauty and earthly satisfaction appear as a vain show, is the counterpart of the former mood of sensuous enjoyment.

For opposite reasons, neither the Greek nor the Jewish mind lent itself readily to mysticism,—the Greek, because of its clear and sunny naturalism; the Jewish, because of its rigid monotheism and its turn towards worldly realism and statutory observance. It is only with the exhaustion of Greek and Jewish civilization that mysticism becomes a prominent factor in Western thought. It appears, therefore, contemporaneously with Christianity, and is a sign of the world-weariness and deep religious need that mark the decay of the old world. Whereas Plato's main problem had been the organization of the perfect state, and Aristotle's intellect had ranged with fresh interest over all departments of the knowable, political speculation had become a mockery with the extinction of free political life, and knowledge as such had lost its freshness for the Greeks of the Roman empire. Knowledge is nothing to these men if it does not show them the infinite reality which is able to fill the aching void within. Accordingly, the last age of Greek philosophy is theosophical in character, and its ultimate end is a practical satisfaction. Neo-Platonism seeks this in the ecstatic intuition of the ineffable One. The systematic theosophy of Plotinus and his successors does not belong to the present article, except so far as it is the presupposition of their mysticism; but, inasmuch as the mysticism of the mediæval church is directly derived from Neo-Platonism through the speculations of the Pseudo-Dionysius, Neo-Platonic mysticism fills an important section in any historical review of the subject.

Neo-Platonism. Neo-Platonism owes its form to Plato, but its underlying motive is the widespread feeling of self-despair and the longing for divine illumination characteristic of the age in which it appears. Before the rise of Neo-Platonism proper we meet with various mystical or semi-mystical expressions of the same religious craving. The contemplative asceticism of the Essenes of Judæa may be mentioned, and, somewhat later, the life of the Therapeutæ on the shores of Lake Mœris. In Philo, Alexandrian Judaism had already seized upon Plato as "the Attic Moses," and done its best to combine his speculations with the teaching of his Jewish prototype. Philo's God is described in terms of absolute transcendency; his doctrine of the Logos or Divine Sophia is a theistical transformation of the Platonic world of ideas; his allegorical interpretation of the Old Testament represents the spiritualistic dissolution of historical Judaism. Philo's ethical ideal is renunciation, contemplation, complete surrender to the divine influence. Apollonius of Tyana and the so-called Neo-Pythagoreans drew similar ethical consequences from their eclectic study of Plato. Wonder-workers like Alexander of Aboniteichos exhibit the grosser side of the longing for spiritual communion. The traits common to Neo-Platonism and all these speculations are well summed up by Zeller (*Philos. der Griechen*, iii. 2. 214) as consisting in—"(1) the dualistic opposition of the divine and the earthly; (2) an abstract conception of God, excluding all *knowledge* of the divine nature; (3) contempt for the world of the senses, on the ground of the Platonic doctrines of matter and of the descent of the soul from a superior world into the body; (4) the theory of intermediate potencies or beings, through whom God acts upon the world of phenomena; (5) the requirement of an ascetic self-emancipation from the bondage of sense and faith in a higher revelation to man when in a state called enthusiasm." Neo-Platonism appears in the first half of the 3d century, and has its greatest representative in Plotinus (204-269 A.D.). He develops the Platonic philosophy into an elaborate system by means of the doctrine of emanation. The One, the Good, and the Idea of the Good were identical in Plato's mind, and the Good was therefore not deprived of intelligible essence. It was not separated from the world of ideas, of which it was represented as either the crown or the sum. By Plotinus, on the contrary, the One is explicitly exalted above the νοῦς and the "ideas"; it transcends existence altogether (ἐπέκεινα τῆς οὐσίας), and is not cognizable by reason. Remaining itself in repose, it rays out, as it were, from its own fulness an image of itself, which is called νοῦς, and which constitutes the system of ideas or the intelligible world. The soul is in turn the image or product of the νοῦς, and the soul by its motion begets corporeal matter. The soul thus faces two ways—towards the νοῦς, from which it springs, and towards the material life, which is its own product. Ethical endeavour consists in the repudiation of the sensible; material existence is

itself estrangement from God. (Porphyry tells us that Plotinus was unwilling to name his parents or his birthplace, and seemed ashamed of being in the body.) Beyond the καθάρσεις, or virtues which purify from sin, lies the further stage of complete identification with God (οὐκ ἔξω ἁμαρτίας εἶναι, ἀλλὰ θεὸν εἶναι). To reach the ultimate goal, thought itself must be left behind; for thought is a form of motion, and the desire of the soul is for the motionless rest which belongs to the One. The union with transcendent deity is not so much knowledge or vision as ecstasy, coalescence, *contact* (ἔκστασις, ἅπλωσις, ἁφή, *Ennead.*, vi. 9. 8-9). But in our present state of existence the moments of this ecstatic union must be few and short; "I myself," says Plotinus simply, "have realized it but three times as yet, and Porphyry hitherto not once."

It will be seen from the above that Neo-Platonism is not mystical as regards the faculty by which it claims to apprehend philosophic truth. It is first of all a system of complete rationalism; it is assumed, in other words, that reason is capable of mapping out the whole system of things. But, inasmuch as a God is affirmed beyond reason, the mysticism becomes in a sense the necessary complement of the would-be all-embracing rationalism. The system culminates in a mystical act, and in the sequel, especially with Iamblichus and the Syrian Neo-Platonists, mystical practice tended more and more to overshadow the theoretical groundwork.

It was probably about the end of the 5th century, just as ancient philosophy was dying out in the schools of Athens, that the speculative mysticism of Neo-Platonism made a definite lodgment in Christian thought through the literary forgeries of the Pseudo-Dionysius. The doctrines of Christianity were by that time so firmly established that the church could look upon a symbolical or mystical interpretation of them without anxiety. The author of the *Theologia Mystica* and the other works ascribed to the Areopagite proceeds, therefore, to develop the doctrines of Proclus with very little modification into a system of esoteric Christianity. God is the nameless and supra-essential One, elevated above goodness itself. Hence "negative theology," which ascends from the creature to God by dropping one after another every determinate predicate, leads us nearest to the truth. The return to God (ἕνωσις, θέωσις) is the consummation of all things and the goal indicated by Christian teaching. The same doctrines were preached with more of churchly fervour by Maximus the Confessor (580-622). Maximus represents almost the last speculative activity of the Greek Church, but the influence of the Pseudo-Dionysian writings was transmitted to the West in the 9th century by Erigena, in whose speculative spirit both the scholasticism and the mysticism of the Middle Ages

ena.

have their rise. Erigena translated Dionysius into Latin along with the commentaries of Maximus, and his system is essentially based upon theirs. The negative theology is adopted, and God is stated to be predicateless Being, above all categories, and therefore not improperly called Nothing. Out of this Nothing or incomprehensible essence the world of ideas or primordial causes is eternally created. This is the Word or Son of God, in whom all things exist, so far as they have substantial existence. All existence is a theophany, and as God is the beginning of all things, so also is He the end. Erigena teaches the restitution of all things under the form of the Dionysian *adunatio* or *deificatio*. These are the permanent outlines of what may be called the philosophy of mysticism in Christian times, and it is remarkable with how little variation they are repeated from age to age.

In Erigena mysticism has not yet separated itself in any way from the dogma of the church. There is no revulsion, as later, from dogma as such, nor is more stress laid upon one dogma than upon another; all are treated upon the same footing, and the whole dogmatic system is held, as it were, in solution by the philosophic medium in which it is presented. No distinction is drawn, indeed, between what is reached by reason and what is given by authority; the two are immediately identical for Erigena. In this he agrees with the speculative mystics everywhere, and differentiates himself from the scholastics who followed him. The distinguishing characteristic of scholasticism is the acceptance by reason of a given matter, the truth of which is independent of rational grounds, and which remains a presupposition even when it cannot be understood. Scholasticism aims, it is true, in its chief representatives, at demonstrating that the content of revelation and the teaching of reason are identical. But what was matter of immanent assumption with Erigena is in them an equating of two things which have been dealt with on the hypothesis that they are separate, and which, therefore, still retain that external relation to one another. This externality of religious truth to the mind is fundamental in scholasticism, while the opposite view is equally fundamental in mysticism. Mysticism is not the voluntary demission of reason and its subjection to an external authority. In that case, all who accept a revelation without professing to understand its content would require to be ranked as mystics; the fierce sincerity of Tertullian's *credo quia absurdum*, Pascal's reconciliation of contradictions in Jesus Christ, and Bayle's half-sneering subordination of reason to faith would all be marks of this standpoint. But such a temper of mind is much more akin to scepticism than to mysticism; it is characteristic of those who either do not feel the need of philosophizing their beliefs, or who have failed in doing so and take refuge in sheer acceptance. Mysticism, on the other hand, is marked on its speculative side by even an overweening confidence in human reason. Nor need this be wondered at if we consider that the unity of the human mind with the divine is its underlying presupposition. Hence where reason is discarded by the mystic it is merely reason overleaping itself; it occurs at the end and not at the beginning of his speculations. Even then there is no appeal to authority; nothing is accepted from without. The appeal is still to the individual, who, if not by reason then by some higher faculty, claims to realize absolute truth and to taste absolute blessedness.

Mysticism first appears in the mediæval church as the protest of practical religion against the predominance of the dialectical spirit. It is so with Bernard of Clairvaux (1091-1153), who condemns Abelard's distinctions and reasonings as externalizing and degrading the faith. Bernard of Clairvaux.

Bernard's mysticism is of a practical cast, dealing mainly with the means by which man may attain to the knowledge and enjoyment of God. Reason has three stages, in the highest of which the mind is able, by abstraction from earthly things, to rise to *contemplatio* or the vision of the divine. More exalted still, however, is the sudden *ecstatic* vision, such as was granted, for example, to Paul. This is the reward of those who are dead to the body and the world. Asceticism is thus the counterpart of mediæval mysticism; and, by his example as well as by his teaching in such passages, Bernard unhappily encouraged practices which necessarily resulted in self-delusion. Love grows with the knowledge of its object, Bernard proceeds, and at the highest stage self-love is so merged in love to God that we love ourselves only for God's sake or because God has loved us. "Te enim quodammodo perdere tanquam qui non sis, et omnino non sentire te ipsum et a te ipso exinaniri et pene annullari, cœlestis est conversationis. . . . Sic affici deificari est." "As the little water-drop poured into a large measure of wine seems to lose its own

nature entirely and to take on both the taste and the colour of the wine, or as iron heated red-hot loses its own appearance and glows like fire, or as air filled with sunlight is transformed into the same brightness so that it does not so much appear to be illuminated as to be itself light,—so must all human feeling towards the Holy One be self-dissolved in unspeakable wise, and wholly transfused into the will of God. For how shall God be all in all if anything of man remains in man? The substance will indeed remain, but in another form, another glory, another power" (*De diligendo Deo*, c. 10). These are the favourite similes of mysticism, wherever it is found.

The Victorines. Mysticism was more systematically developed by Bernard's contemporary Hugo of St Victor (1096-1141). The Augustinian monastery of St Victor near Paris became the headquarters of mysticism during the 12th century. It had a wide influence in awakening popular piety, and the works that issued from it formed the text-books of mystical and pietistic minds in the centuries that followed. Hugo's pupil, Richard of St Victor, declares, in opposition to dialectic scholasticism, that the objects of mystic contemplation are partly above reason, and partly, as in the intuition of the Trinity, contrary to reason. He enters at length into the conditions of ecstasy and the yearnings that precede it. Walter, the third of the Victorines, carried on the polemic against the dialecticians. Bonaventura (1221-74) was a diligent student of the Victorines, and in his *Itinerarium mentis ad Deum* maps out the human faculties in a similar fashion. He introduces the terms "apex mentis" and "scintilla" (also "synderesis" or συντήρησις) to describe the faculty of mystic intuition. Bonaventura runs riot in phrases to describe the union with God, and his devotional works were much drawn upon by mystical preachers. Fully a century later, when the system of scholasticism was gradually breaking up under the predominance of Occam's nominalism, Pierre d'Ailly (1350-1425), and his more famous scholar John Gerson (1363-1429), chancellor of the university of Paris, are found endeavouring to combine the doctrines of the Victorines and Bonaventura with a nominalistic philosophy. They are the last representatives of mysticism within the limitations imposed by scholasticism.

Early German mystics. From the 12th and 13th centuries onward there is observable in the different countries of Europe a widespread reaction against the growing formalism and worldliness of the church and the scandalous lives of many of the clergy. Men began to feel a desire for a theology of the heart and an unworldly simplicity of life. Thus there arose in the Netherlands the Beguines and Beghards, in Italy the Waldenses (without, however, any mystical leaning), in the south of France and elsewhere the numerous sect or sects of the Cathari, and in Calabria the apocalyptic gospel of Joachim of Floris, all bearing witness to the commotion of the time. The lay societies of the Beghards and Beguines (for men and women respectively) date from the end of the 12th century, and soon became extremely popular both in the Low Countries and on the Rhine. They were free at the outset from any heretical taint, but were never much in favour with the church. In the beginning of the 13th century the foundation of the Dominican and Franciscan orders furnished a more ecclesiastical and regular means of supplying the same wants, and numerous convents sprang up at once throughout Germany. The German mind was a peculiarly fruitful soil for mysticism, and, in connexion either with the Beguines or the church organization, a number of women appear about this time, combining a spirit of mystical piety and asceticism with sturdy reformatory zeal directed against the abuses of the time. Even before this we hear of the prophetic visions of Hildegard of Bingen (a contemporary of St Bernard) and Elizabeth of Schönau. In the 13th century Elizabeth of Hungary, the pious landgravine of Thuringia, assisted in the foundation of many convents in the north of Germany. For an account of the chief of these female saints the reader is referred to the first volume of Preger's *Geschichte der deutschen Mystik*. Mechthild of Magdeburg appears to have been the most influential, and her book *Das fliessende Licht der Gottheit* is important as the oldest work of its kind in German. It proves that much of the terminology of German mysticism was current before Eckhart's time. Mechthild's clerico-political utterances show that she was acquainted with the "eternal gospel" of Joachim of Floris. Joachim had proclaimed the doctrine of three world-ages—the kingdom of the Father, of the Son, and of the Spirit. The reign of the Spirit was to begin with the year 1260, when the abuses of the world and the church were to be effectually cured by the general adoption of the monastic life of contemplation. Very similar to this in appearance is the teaching of Amalrich of Bena (*ob.* 1207); but, while the movements just mentioned were reformatory without being heretical, this is very far from being the case with the mystical pantheism derived by Amalrich from the writings of Erigena. His followers held a progressive revelation of God in the ages of the Father, Son, and Holy Spirit. Just as the Mosaic dispensation came to an end with the appearance of Christ, so the sacraments of the new dispensation have lost their meaning and efficacy since the incarnation of God as Holy Spirit in the Amalricans. With this opposition to the church they combine a complete antinomianism, through the identification of all their desires with the impulses of the divine Spirit. Amalrich's teaching was condemned by the church, and his heresies led to the public burning of Erigena's *De divisione naturæ* in 1225. The sect of the New Spirit, or of the Free Spirit as it was afterwards called, spread widely through the north of France and into Switzerland and Germany. They were especially numerous in the Rhineland in the end of the 13th and during the 14th century; and they seem to have corrupted the originally orthodox communities of Beghards, for Beghards and Brethren of the Free Spirit are used henceforward as convertible terms, and the same immoralities are related of both. Such was the seed-ground in which what is specifically known as German mysticism sprang up.

In Meister Eckhart (1260-1329;—see ECKHART) the German mind definitively asserts its pre-eminence in the sphere of speculative mysticism. Eckhart was a distinguished son of the church; but in reading his works we feel at once that we have passed into quite a different sphere of thought from that of the churchly mystics; we seem to leave the cloister behind and to breathe a freer atmosphere. The scholastic mysticism was, for the most part, practical and psychological in character. It was largely a devotional aid to the realization of present union with God; and, so far as it was theoretical, it was a theory of the faculties by which such a union is attainable. Mysticism was pieced on somewhat incongruously to a scholastically accepted theology; the feelings and the intellect were not brought together. But in Eckhart the attitude of the churchman and traditionalist is entirely abandoned. Instead of systematizing dogmas, he appears to evolve a philosophy by the free exercise of reason. His system enables him to give a profound significance to the doctrines of the church; but, instead of the system being accommodated to the doctrines, the doctrines—and especially the historical facts—acquire a new sense in the system, and often become only a mythical representation of speculative truth. The freedom with which Eckhart treats historical Christianity allies him much more to the German idealists of the 19th century than to his scholastic prede- Eckhart.

reason. In his speculative depth as well as in the fondness for reconciling apparent contradictions which often lends an air of paradox to his statements Eckhart bears a striking resemblance to Hegel; but in some determinations of his system, such as his doctrine of the Absolute, he approaches more nearly to Schelling. In view of these affinities it has been customary to say that his interest is predominantly intellectual and that he is lacking in religious warmth. But this is largely due to the fusion of intellect and feeling which is often found in highly speculative natures. Eckhart's system is in itself the expression or formulation of religious feeling, and the speculative statement possesses for him a rich spiritual unction of its own. In this he is the typical representative of German, in opposition to what is often called Romanic, mysticism. The latter, both in earlier times and in its later Catholic representatives, confines itself to the facts of religious feeling without showing itself attracted by ontological speculation.

Eckhart distinguishes between the godhead and God. The godhead is the absolute Essence (*Wesen*), unknowable not only by man but also by itself; it is darkness and absolute indeterminateness, "Nicht" in contrast to "Icht" or definite and knowable existence. Yet it is the potentiality of all things, and its nature is, in a triadic process, to come to consciousness of itself as the triune God. Creation is not a temporal act, but an eternal necessity of the divine nature. I am as necessary to God, Eckhart is fond of saying, as God is necessary to me. In my knowledge and love God knows and loves Himself. "The eye with which I see God is the same eye with which God sees me. My eye and God's eye are one eye, one vision, one recognition, one love." To know God, we must become ignorant of ourselves and of all creatures. "Couldst thou annihilate thyself for a moment, thou wouldst possess all that God is in Himself." The complete renunciation of selfhood is called by Eckhart "*decease*;" and when I am in this state God brings forth His Son in me. Or, conversely, it is I who beget God anew in my soul; "God has begotten me from eternity that I may be Father and beget Him who begat me." Our identity with God is recognized by the purely rational and uncreated activity of the soul, which Eckhart calls the "Fünklein," or spark. By this we press on beyond God into the abyss of the godhead, and Eckhart prays paradoxically "to be rid of God, that is, that God by His grace would bring him into the Essence—that Essence which is above God and above distinction."

In spite of Eckhart's daring assertions of the identity of the human and the divine, there is no reason to call in question his genuinely religious and Christian spirit. His spirit, however, was Christian in a wide sense rather than ecclesiastical; it showed itself in zeal for the upbuilding of Christian life among the people. The condemnation of the church had its effect in later times in obscuring Eckhart's importance, but it did not avail to check his powerful influence upon his contemporaries. They constantly appeal to him as "the master," the "wise," the "divine" master, "from whom God concealed nothing."

The political circumstances of Germany in the first half of the 14th century were in the last degree disastrous. The war between the rival emperors, Frederick of Austria and Louis of Bavaria, and the interdict under which the latter was placed in 1324 inflicted extreme misery upon the unhappy people. From some places the interdict was not removed for twenty-six years. Men's minds were pained and disquieted by the conflict of duties and the absence of spiritual consolation. The country was also visited by a succession of famines and floods, and in 1348 the Black Death swept over Europe like a terrible scourge. In the midst of these unhappy surroundings religion became more inward in men of real piety, and the desire grew among them to draw closer the bonds that united them to one another. Thus arose the society of the Friends of God (*Gottesfreunde*) in the south and west of Germany, spreading as far as Switzerland on the one side and the Netherlands on the other. They formed no exclusive sect. They often took opposite sides in politics, and they also differed in the type of their religious life; but they uniformly desired to strengthen one another in living intercourse with God. Among them chiefly the followers of Eckhart were to be found. Such were Heinrich Suso of Constance (1295-1366) and John Tauler of Strasburg (1300-61), the two most celebrated of his immediate disciples. Suso was a remarkable combination of self-torturing austerity with an inexhaustible play of poetic fancy. He has been called "the minnesinger of the love of God." Tauler's eloquence may be said to have made him the centre of religious life in the south-west of Germany for more than quarter of a century. In his sermons, while the standpoint is the same as Eckhart's, the speculative groundwork tends, as is natural, to be less insisted on, and more scope is given to its practical consequences and to direct religious exhortation. Nicolas of Basel, the mysterious layman from whose visit Tauler dates his true religious life, seems to have been the chief organizing force among the Gottesfreunde. He was known as "the great friend of God in the Oberland," and Basel continued to be a quiet haven of reunion for the members of the society. Tauler and others retired thither at intervals from the political storms of the time. The society counted many members among the pious women in the convents of southern Germany. Such were Christina Ebner of Engelthal near Nuremberg, and Margaretha Ebner of Medingen in Swabia. Laymen also belonged to it, like Hermann von Fritzlar and Rulman Merswin, the rich banker of Strasburg (author of a mystical work, *Buch der neun Felsen*, on the nine rocks or upward steps of contemplation). Letters passed between the members, as well as presents of books or relics. Some of them, like Heinrich von Nördlingen, the friend of Margaretha Ebner, went much from place to place, and in that way helped to keep up a living connexion among the friends. It was doubtless one of their number who sent forth anonymously from the house of the Teutonic Order in Frankfort the famous handbook of mystical devotion called *Eine deutsche Theologie*. Shortly after the middle of the century most of the friends of whom anything is known drop out of sight. But the combination of warm piety and spiritual freedom in Tauler's sermons and the *Deutsche Theologie* exercised a continuous influence on the religious life of Germany till the time of Luther. As is well known, the *Deutsche Theologie* was first published in 1516 by Luther, who accompanied it by a preface expressing his own obligations to the "noble book," and ranking it inferior only to the Bible and St Augustine. The fact that the book was put into his hands by Staupitz, the vicar-general of the Augustinian order, shows that Luther's high estimate was not singular at the time.

The Gottesfreunde.

Ruysbroeck.

John Ruysbroeck (1293-1381), the father of mysticism in the Netherlands, stood in connexion with the Friends of God, and Tauler is said to have visited him in his seclusion at Vauvert (Grünthal) near Brussels. He was decisively influenced by Eckhart, though there is noticeable occasionally a shrinking back from some of Eckhart's phraseology. The sect of the Free Spirit is the frequent object of his polemic, and this leads him into somewhat careful definitions of truth and error. For the rest, Ruysbroeck's mysticism is more of a practical than a speculative cast. He is chiefly occupied with the means whereby the *unio mystica* is to be attained, whereas Eckhart dwells on the

union as an ever-present fact, and dilates on its metaphysical implications. Towards the end of Ruysbroeck's life, in 1378, he was visited by the fervid lay-preacher Gerhard Groot (1340-84), who was so impressed by the life of the community at Vauvert that he conceived the idea of founding a Christian brotherhood bound by no monastic vows, but living together in simplicity and piety with all things in common, after the apostolic pattern. This was the origin of the Brethren of the Common Lot (or Common Life). The first house of the Brethren was founded at Deventer by Gerhard Groot and his youthful friend Florentius Radewyn. Similar brother-houses soon sprang up in different places throughout the Low Countries and Westphalia, and even Saxony. Thomas a Kempis (1380-1471), to whom the brotherhood chiefly owes its fame, forms the subject of a separate article.

Mystics and the Reformation.

It has been customary for Protestant writers to represent the mystics of Germany and Holland as precursors of the Reformation. In a sense this is true; and the direct influence of Tauler and the *Deutsche Theologie* upon Luther has already been referred to. But it conveys a false impression if it is understood to mean that these men protested against the doctrines of the church in the way the Reformers felt themselves called upon to do. There is no sign that Tauler, for example, or Ruysbroeck, or Thomas a Kempis had felt the dogmatic teaching of the church jar in any single point upon their religious consciousness. Nevertheless, mysticism did prepare men in a very real way for a break with the traditional system. Mysticism instinctively recedes from formulas that have become stereotyped and mechanical into the perennially fresh experience of the individual. In the first place, therefore, it brings into prominence only those broad and universal doctrines which it finds to be of vital and present moment for the inward life, while others, though they may have an important place in the churchly system, are (unconsciously) allowed to slip into temporary forgetfulness. It is thus we must explain that almost total absence of distinctively Romish doctrine in Thomas a Kempis which makes the *Imitation* as acceptable to the Protestant as to the devout Catholic. In the second place, mysticism accustoms men to deal with their experience for themselves at first hand, and to test the doctrines presented to them by that standard. This growth of spiritual freedom is especially to be marked in the German mystics. It is to be noted, however, that mysticism affords in itself no foundation for a religious community. Its principle is pure inwardness, but it possesses no norm by which the extravagances of the individual may be controlled. Thus, when the Reformers appeared to do their work, the mystics were found opposing the new authority of Scripture to the full as bitterly as they had opposed the old authority of the church. To the thoroughgoing mystic individualist the one standard is as external as the other. When Cellarius was called upon by Luther to substantiate his positions by reference to Scripture, he struck the table with his fist and declared it an insult to speak so to a man of God. A germ of reason may be discerned in this indignation, but none the less we must recognize that, while mysticism showed itself capable at the Reformation of dissolving society into anarchy and atomism, it showed itself perfectly destitute of a reconstructive power. The same people who would claim the pre-Reformation mystics as Protestants in disguise are indignant at the way in which the later mystics oppose, or hold aloof from, the Reformation movement. But the truth seems to be that, in both cases, mysticism was true to its principle. Without some fixed letter to attach itself to, it sinks away into utter formlessness; but its relation to the system is always more or less one of opposition to what it regards as external.

Later German mystics.

The wild doctrines of Thomas Münzer and the Zwickau prophets, merging eventually into the excesses of the Peasants' War and the doings of the Anabaptists in Münster, first roused Luther to the dangerous possibilities of mysticism as a disintegrating force. He was also called upon to do battle for his principle against men like Schwenkfeld (1490-1561) and Sebastian Frank (1500-45), the latter of whom developed a system of pantheistic mysticism, and went so far in his opposition to the letter as to declare the whole of the historical element in Scripture to be but a mythical representation of eternal truth. Valentin Weigel (1533-88), who stands under manifold obligations to Frank, represents also the influence of the semi-mystical physical speculation that marked the transition from scholasticism to modern times. The final breakdown of scholasticism as a rationalized system of dogma may be seen in Nicolaus of Cusa (1401-64), who received his education, like Thomas a Kempis, at Deventer, and afterwards rose to be a cardinal of the church. He distinguishes between the *intellectus* and the discursively acting *ratio* almost precisely in the style of later distinctions between the reason and the understanding. The intellect combines what the understanding separates; hence Nicolaus teaches the principle of the *coincidentia contradictoriorum*. If the results of the understanding go by the name of knowledge, then the higher teaching of the intellectual intuition may be called ignorance—ignorance, however, that is conscious of itself, *docta ignorantia*. "Intuitio," "speculatio," "visio sine comprehensione," "comprehensio incomprehensibilis," "mystica theologia," "tertius cœlus," are some of the terms he applies to this knowledge above knowledge; but in the working out of his system he is remarkably free from extravagance. Nicolaus's doctrines were of influence upon Giordano Bruno and other physical philosophers of the 15th and 16th centuries. All these physical theories are blended with a mystical theosophy, of which the most remarkable example is, perhaps, the chemico-astrological speculations of Paracelsus (1493-1541). The influence of Nicolaus of Cusa and Paracelsus mingled in Valentin Weigel with that of the *Deutsche Theologie*, Osiander, Schwenkfeld, and Frank. Weigel, in turn, handed on these influences to Jacob Boehme (1575-1624), *philosophus teutonicus*, and father of the chief developments of theosophy in modern Germany. See BOEHME.

Other forms of mysticism.

Mysticism did not cease within the Catholic Church at the Reformation. In St Theresa (1515-82) and John of the Cross the counter-reformation can boast of saints second to none in the calendar for the austerity of their mortifications and the rapture of the visions to which they were admitted. But, as was to be expected, their mysticism moves in that comparatively narrow round, and consists simply in the heaping up of these sensuous experiences. The speculative character has entirely faded out of it, or rather has been crushed out by the tightness with which the directors of the Roman Church now held the reins of discipline. Their mysticism represents, therefore, no widening or spiritualizing of their theology; in all matters of belief they remain the docile children of their church. The gloom and harshness of these Spanish mystics are absent from the tender, contemplative spirit of François de Sales (1567-1622); and in the quietism of Madame Guyon (1648-1717) and Miguel de Molinos (1627-96) there is again a sufficient implication of mystical doctrine to rouse the suspicion of the ecclesiastical authorities. Quietism, name and thing, became the talk of all the world through the bitter and protracted controversy to which it gave rise between Fénelon and Bossuet.

In the 17th century mysticism is represented in the philosophical field by the so-called Cambridge Platonists, and especially by Henry More (1614-87), in whom the

influence of the Kabbalah is combined with a species of Christianized Neo-Platonism. Pierre Poiret (1646-1719) exhibits a violent reaction against the mechanical philosophy of Descartes, and especially against its consequences in Spinoza. He was an ardent student of Tauler and Thomas a Kempis, and became an adherent of the quietistic doctrines of Madame Bourignon. His philosophical works emphasize the passivity of the reason. The first influence of Boehme was in the direction of an obscure religious mysticism. J. G. Gichtel (1638-1710), the first editor of his complete works, became the founder of a sect called the Angel-Brethren. All Boehme's works were translated into English in the time of the Commonwealth, and regular societies of Behmenists were formed in England and Holland. Later in the century he was much studied by the members of the Philadelphian Society, John Pordage, Thomas Bromley, Jane Lead, and others. The mysticism of William Law (1686-1761) and of St Martin in France (1743-1803), who were also students of Boehme, is of a much more elevated and spiritual type. The "Cherubic Wanderer," and other poems, of Johann Scheffler (1624-77), known as Angelus Silesius, are more closely related in style and thought to Eckhart than to Boehme.

The religiosity of the Quakers, with their doctrines of the "inner light" and the influence of the Spirit, has decided affinities with mysticism; and the quaint autobiography of George Fox (1624-91), the founder of the sect, proceeds throughout on the assumption of supernatural guidance. Stripped of its definitely miraculous character, the doctrine of the inner light may be regarded as the familiar mystical protest against formalism, literalism, and scripture-worship. Swedenborg, though selected by Emerson in his *Representative Men* as the typical mystic, belongs rather to the history of spiritualism than to that of mysticism as understood in this article. He possesses the cool temperament of the man of science rather than the fervid Godward aspiration of the mystic proper; and the speculative impulse which lies at the root of this form of thought is almost entirely absent from his writings. Accordingly, his supernatural revelations resemble a course of lessons in celestial geography more than a description of the beatific vision.

Philosophy since the end of the last century has frequently shown a tendency to diverge into mysticism. This has been especially so in Germany. The term mysticism is, indeed, often extended by popular usage and philosophical partisanship to the whole activity of the post-Kantian idealists. In this usage the word would be equivalent to the more recent and scarcely less abused term, transcendentalism, and as such it is used even by a sympathetic writer like Carlyle; but this looseness of phraseology only serves to blur important distinctions. However absolute a philosopher's idealism may be, he is erroneously styled a mystic if he moves towards his conclusions only by the patient labour of the reason. Hegel therefore, to take an instance, can no more fitly be classed as a mystic than Spinoza can. It would be much nearer the truth to take both as types of a thoroughgoing rationalism. In either case it is of course open to any one to maintain that the apparent completeness of synthesis really rests on the subtle intrusion of elements of feeling into the rational process. But in that case it might be difficult to find a systematic philosopher who would escape the charge of mysticism: and it is better to remain by long-established and serviceable distinctions. Where philosophy despairs of itself, exults in its own overthrow, and yet revels in the "mysteries" of a speculative Christianity, as in J. G. Hamann (1730-88), the term mysticism may be fitly applied. So, again, it is in place where the movement of revulsion from a mechanical philosophy takes the form rather of immediate assertion than of reasoned demonstration, and where the writers, after insisting generally on the spiritual basis of phenomena, either leave the position without further definition, or expressly declare that the ultimate problems of philosophy cannot be reduced to articulate formulas. Examples of this are men like Novalis, Carlyle, and Emerson, in whom philosophy may be said to be impatient of its own task. Schelling's explicit appeal in the "*Identitatsphilosophie*" to an intellectual intuition of the Absolute, is of the essence of mysticism, both as an appeal to a supra-rational faculty and as a claim not merely to know but to realize God. The opposition of the reason to the understanding, as used by Coleridge, is not free from the first of these faults. The later philosophy of Schelling and the philosophy of Franz von Baader, both largely founded upon Boehme, belong rather to theosophy than to mysticism proper.

Authorities.—The authorities for the teaching of individual mystics will be found under their names. Besides the sections on mysticism in the general histories of philosophy by Erdmann and Ueberweg, and in works on church history and the history of dogma, reference may be made for the mediæval period to Heinrich Schmid, *Der Mysticismus in seiner Entstehungsperiode*, Jena, 1824; Helfferich, *Die christliche Mystik*, Hamburg, 1842; Noack, *Die christliche Mystik des Mittelalters*, Konigsberg, 1853. On the German mystics the works are very numerous, but decidedly the best is the *Geschichte der deutschen Mystik*, in course of publication by W. Preger. The first volume, published at Leipsic in 1874, deals with Meister Eckhart and his precursors; the second, which appeared in 1881, deals with Suso and the general development of mysticism in Eckhart's school, but without including Tauler. The works of Eckhart and his precursors are contained in Pfeiffer's *Deutsche Mystiker des 14ten Jahrhunderts*, vol. i. (1845), vol. ii. (1857). The *Theologia Germanica* and a selection from Tauler's *Sermons* have been translated into English by Miss Susannah Winkworth. (A. SE.)

MYTHOLOGY

MYTHOLOGY (μυθολογία) is the science which examines μῦθοι, or legends of cosmogony and of gods and heroes. Mythology is also used as a term for these legends themselves. Thus when we speak of "the mythology of Greece" we mean the whole body of Greek divine and heroic and cosmogonic legends. When we speak of the "science of mythology" we refer to the various attempts which have been made to explain these ancient narratives. Very early indeed in the history of human thought men awoke to the consciousness that their religious stories were much in want of explanation. The myths of civilized peoples, as of Greeks and the Aryans of India, contain two elements, the rational and the irrational. The rational myths are those which represent the gods as beautiful and wise beings. The Artemis of the *Odyssey* "taking her pastime in the chase of boars and swift deer, while with her the wild wood-nymphs disport them, and high over them all she rears her brow, and is easily to be known where all are fair," is a perfectly rational mythic representation of a divine being. We feel, even now, that the conception of a "queen and huntress, chaste and fair," the lady warden of the woodlands, is a beautiful and natural fancy which requires no explanation. On the other hand, the Artemis of Arcadia, who is confused with the nymph Callisto, who, again, is said to have become a she-bear, and later a star, and the Brauronian Artemis, whose maiden ministers danced a bear-dance (ἀρκτεύειν; compare Harpocration on this word), are goddesses whose legend seems unnatural, and is felt to need explanation. Or, again, there is nothing not explicable and natural in the con-

ception of the Olympian Zeus as represented by the great chryselephantine statue of Zeus at Olympia, or in the Homeric conception of Zeus as a god who "turns everywhere his shining eyes" and beholds all things. But the Zeus whose grave was shown in Crete, or the Zeus who played Demeter an obscene trick by the aid of a ram, or the Zeus who, in the shape of a swan, became the father of Castor and Pollux, or the Zeus who was merely a rough stone, or the Zeus who deceived Hera by means of a feigned marriage with an inanimate object, or the Zeus who was afraid of Attes, is a being whose myth is felt to be unnatural and in great need of explanation. It is this irrational and unnatural element—as Mr Max Müller says, "the silly, senseless, and savage element"—that makes mythology the puzzle which men have so long found it.

Early Explanations of Myths.—The earliest attempts at a crude science of mythology were efforts to reconcile the legends of the gods and heroes with the religious sentiment which recognized in these beings objects of worship and respect. Closely as religion and myth are intertwined, it is necessary to hold them apart for the purposes of this discussion. Religion may here be defined as the conception of divine or at least supernatural powers, entertained by men in moments of gratitude or of need and distress, in hours of weakness, when, as Homer says, "all folk yearn after the gods." Now this conception may be rude enough, and it is nearly related to purely magical ideas, to efforts to secure supernatural aid by magical ceremonies. Still the roughest form of spiritual prayer has for its basis the hypothesis of beneficent beings, visible or invisible. The senseless stories or myths about the gods are soon felt to be at variance with this hypothesis. As an example we may take the instance of Qing, the Bushman hunter. Qing, when first he met white men, was asked about his religion. He began to explain, and mentioned Cagn. Mr Orpen, the chief magistrate of St John's Territory, asked, "Is Cagn good or malicious? how do you pray to him?" Answer (in a low imploring tone), "'O Cagn! O Cagn! are we not your children? do you not see our hunger? give us food;' and he gives us both hands full" (*Cape Monthly Magazine*, July 1874). Here we see the *religious* view of Cagn, the Bushman god. But in the *mythological* account of Cagn given by Qing he appears as a kind of grasshopper, supernaturally endowed, the hero of a most absurd cycle of senseless adventures. Even religion is affected by these irrational notions, and the gods of savages and of many civilized peoples are worshipped with cruel, obscene, and irrational rites. But, on the whole, the religious sentiment strives to transcend the mythical conceptions of the gods, and is shocked and puzzled by the mythical narratives. As soon as this sense of perplexity is felt, by poets, by priests, or by most men in an age of nascent criticism, explanations of what is most crude and absurd in the myths are put forward. Men ask themselves why their gods are worshipped in the form of beasts, birds, and fishes; why their gods are said to have prosecuted their amours in bestial shapes; why they are represented as lustful and passionate—thieves, robbers, murderers, and adulterous. The answers to these questions sometimes become myths themselves. Thus both the Mangaians and the Egyptians have been puzzled by their own gods in the form of beasts. The Egyptians invented an explanation—itself a myth—that in some moment of danger the gods concealed themselves from their foes in the shapes of animals.[1] The Mangaians, according to Mr Gill, hold that "the heavenly family had taken up their abode in these birds, fishes, and reptiles."[2]

A people so curious and refined as the Greeks were certain to be greatly perplexed by even such comparatively pure mythical narratives as they found in Homer, still more by the coarser legends of Hesiod, and above all by the ancient local myths preserved by local priesthoods. Thus, in the 6th century before Christ, Xenophanes of Colophon severely blamed the poets for their unbecoming legends, and boldly called certain myths "the fables of men of old."[3] Theagenes of Rhegium (520 B.C.?), according to the scholiast on *Iliad*, xx. 67,[4] was the author of a very ancient system of mythology. Admitting that the fable of the battle of the gods was "unbecoming," if literally understood, Theagenes represented it as an allegorical account of the war of the elements. Apollo, Helios, and Hephæstus were fire, Hera was air, Poseidon was water, Artemis was the moon, καὶ τὰ λοιπὰ ὁμοίως. Or, by another system, the names of the gods represented moral and intellectual qualities. Heraclitus, too, disposed of the myth of the bondage of Hera as allegorical philosophy. Socrates, in the *Cratylus* of Plato, expounds "a philosophy which came to him all in an instant," an explanation of the divine beings based on crude philological analyses of their names. Metrodorus, rivalling some recent flights of conjecture, resolved not only the gods but even heroes like Agamemnon, Hector, and Achilles "into elemental combinations and physical agencies."[5] Euripides makes Pentheus (but he was notoriously impious) advance a "rationalistic" theory of the story that Dionysus was stitched up in the thigh of Zeus. When Christianity became powerful the heathen philosophers evaded its satire by making more and more use of the allegorical and non-natural system of explanation. That method has two faults. First (as Arnobius and Eusebius reminded their heathen opponents), the allegorical explanations are purely arbitrary, depend upon the fancy of their author, and are all equally plausible and equally unsupported by evidence.[6] Secondly, there is no proof at all that, in the distant age when the myths were developed, men entertained the moral notions and physical philosophies which are supposed to be "wrapped up," as Cicero says, "in impious fables." Another system of explanation is that associated with the name of Euemerus (316 B.C.). According to this author, the myths are history in disguise. All the gods were once men, whose real feats have been decorated and distorted by later fancy. This view suited Lactantius, St Augustine, and other early Christian writers very well. They were pleased to believe that Euemerus "by historical research had ascertained that the gods were once but mortal men." Precisely the same convenient line was taken by Sahagun in his account of Mexican religious myths. As there can be no doubt that the ghosts of dead men have been worshipped in many lands, and as the gods of many faiths are tricked out with attributes derived from ancestor-worship, the system of Euemerus retains some measure of plausibility. While we need not believe with Euemerus and with Mr Herbert Spencer that the god of Greece or the god of the Hottentots was once a man, we cannot deny that the myths of both these gods have passed through and been coloured by the imaginations of men who practised the worship of real ancestors. For example, the Cretans showed the tomb of Zeus, and the Phocians (Pausanias, x. 5) daily poured blood of victims into the tomb of a hero, obviously by way of feeding his ghost. The Hottentots show many tombs of their god, Tsui-Goab, and tell tales about his death; they also pray regularly for aid at the tombs of their own parents.[7] We

may therefore say that, while it is rather absurd to believe that Zeus and Tsui-Goab were once real men, yet their myths are such as would be developed by people accustomed, among other forms of religion, to the worship of dead men. Very probably portions of the legends of real men have been attracted into the mythic accounts of gods of another character, and this is the element of truth at the bottom of Euemerism. This is not the place to deal fully with the modern form of the system as set forth by Mr Herbert Spencer.

Later Explanations of Mythology.—The ancient systems of explaining what needed explanation in myths were, then, physical, ethical, religious, and historical. One student, like Theagenes, would see a physical philosophy underlying Homeric legends. Another, like Porphyry, would imagine that the meaning was partly moral, partly of a dark theosophic and religious character. Another would detect moral allegory alone, and Aristotle expresses the opinion that the myths were the inventions of legislators "to persuade the many, and to be used in support of law" (*Met.*, xi. 8, 19). A fourth, like Euemerus, would get rid of the supernatural element altogether, and find only an imaginative rendering of actual history. When Christians approached the problem of heathen mythology, they sometimes held, with St Augustine, a form of the doctrine of Euemerus.[1] In other words, they regarded Zeus, Aphrodite, and the rest as real persons, diabolical not divine. Some later philosophers, especially of the 17th century, misled by the resemblance between Biblical narratives and ancient myths, came to the conclusion that the Bible contains a pure, the myths a distorted, form of an original revelation. The abbé Banier published a mythological compilation in which he systematically resolved all the Greek myths into ordinary history.[2] Bryant published (1774) *A New System, or an Analysis of Ancient Mythology, wherein an Attempt is made to divest Tradition of Fable*, in which he talked very learnedly of "that wonderful people, the descendants of Cush," and saw everywhere symbols of the ark and traces of the Noachian deluge. Thomas Taylor, at the end of the 18th century, indulged in much mystical allegorizing of myths, as in the notes to his translation of Pausanias (1794). At an earlier date (1760) De Brosses struck on the true line of interpretation in his little work *Du Culte des Dieux Fétiches, ou Parallèle de l'ancienne Religion de l'Égypte avec la Religion actuelle de Nigritie.* In this tract De Brosses explained the animal-worship of the Egyptians as a survival among a civilized people of ideas and practices springing from the intellectual condition of savages, and actually existing among negroes. A vast symbolical explanation of myths and mysteries was attempted by Friedrich Creuzer.[3] The learning and sound sense of Lobeck, in his *Aglaophamus*, exploded the idea that the Eleusinian and other mysteries revealed or concealed matter of momentous religious importance. It ought not to be forgotten that Lafitau, a Jesuit missionary in North America, while inclined to take a mystical view of the secrets concealed by Iroquois myths, had also pointed out the savage element surviving in Greek mythology.[4]

The Most Recent Mythological Systems.—Up to a very recent date students of mythology were hampered by orthodox traditions, and still more by ignorance of the ancient languages and of the natural history of man. Only recently have Sanskrit and the Egyptian and Chaldæan languages become books not absolutely sealed. Again, the study of the evolution of human institutions from the lowest savagery to civilization is essentially a novel branch of research, though ideas derived from an unsystematic study of anthropology are at least as old as Aristotle. The new theories of mythology are based on the belief that "it is man, it is human thought and human language combined, which naturally and necessarily produced the strange conglomerate of ancient fable."[5] But, while there is now universal agreement so far, modern mythologists differ essentially on one point. There is a school (with internal divisions) which regards ancient fable as almost entirely "a disease of language," that is, as the result of confusions arising from misunderstood terms that have survived in speech after their original significance was lost. Another school (also somewhat divided against itself) believes that misunderstood *language* played but a very slight part in the evolution of mythology, and that the irrational element in myths is merely the survival from a condition of *thought* which was once common, if not universal, but is now only found among savages, and to a certain extent among children. The former school considers that the state of thought out of which myths were developed was produced by decaying language; the latter maintains that the corresponding phenomena of language were the reflexion of thought. For the sake of brevity we might call the former the "philological" system, as it rests chiefly on the study of language, while the latter might be styled the "historical" or "anthropological" school, as it is based on the study of man in the sum of his manners, ideas, and institutions.

The System of Mr Max Müller.—The most distinguished and popular advocate of the philological school is Mr Max Müller, whose ideas must now be stated. Their exposition is chiefly to be found in Mr Müller's *Selected Essays* and in his *Lectures on Language.* As the opposite system, the historical or anthropological system, is that which will be adopted in the remainder of this article, our criticism of Mr Müller's ideas must be accepted as that of an opponent. The problem set himself by Mr Muller is to explain what he calls "the silly, savage, and senseless" element in mythology (*Sel. Ess.*, i. 578).

(1.) Mr Müller says (speaking of the Greeks), "their poets had an instinctive aversion to everything excessive or monstrous, yet they would relate of their gods what would make the most savage of Red Indians creep and shudder,"—stories, that is, of the cannibalism of Demeter, of the mutilation of Uranus, the cannibalism of Cronus, who swallowed his own children, and the like. "Among the lowest tribes of Africa and America we hardly find anything more hideous and revolting."

(2.) Mr Müller refers the beginning of his system of mythology to the discovery of the connexion of the Indo-European or, as they are called, "Aryan" languages. Celts, Germans, speakers of Sanskrit and Zend, Latins and Greeks, all prove by their languages that their tongues may be traced to one family of speech. The comparison of the various words which, in different forms, are common to all Indo-European languages must inevitably throw much light on the original meaning of these words. Take, for example, the name of a god, Zeus, or Athene, or any other. The word may have no intelligible meaning in Greek, but its counterpart in the allied tongues, especially in Sanskrit or Zend, may reveal the original significance of the terms. "To understand the origin and meaning of the names of the Greek gods, *and to enter into the original intention of the fables told of each*, we must take into account the collateral evidence supplied by Latin, German,

Sanskrit, and Zend philology" (*Lect. on Lang.*, 2d ser., p. 406). A name may be intelligible in Sanskrit which has no sense in Greek. Thus Athene is a divine name without meaning in Greek, but Mr Müller advances reasons for supposing that it is identical with *ahana*, "the dawn," in Sanskrit. It is his opinion, apparently, that whatever story is told of Athene must have originally been told of the dawn, and that we must keep this before us in attempting to understand the legends of Athene. Thus (*op. cit.*, p. 410), he says, "we have a right to explain all that is told of him" (Agni, "fire") "as originally meant for fire." To take another example, Mr Müller proves by aid of Sanskrit philology that Zeus originally meant the sky, and, as a result, "there was nothing that could be told of the sky that was not in some form or other ascribed to Zeus." If, then (to take an example of our own), we read that Zeus, to pacify the jealousy of Demeter, mutilated a ram, and pretended to have mutilated himself, are we to suppose that this story had originally a meaning in reference to the sky? The system, at all events, is simply this: the original meaning of the names of gods must be ascertained by comparative philology. The names, as a rule, will be found to denote elemental phenomena. And the silly, savage, and senseless elements in the legends of the gods will be shown to have a natural significance, as descriptions of sky, storms, sunset, water, fire, dawn, twilight, the life of earth, and other celestial and terrestrial existences. Stated in the barest form, these results do not differ greatly from the conclusions of Theagenes of Rhegium, who held that "Hephæstus was fire, Hera was air, Poseidon was water, Artemis was the moon, καὶ τὰ λοιπὰ ὁμοίως." But Mr Müller's system is based on scientific philology, not on conjecture, and is supported by a theory, which we shall try to explain, of the various processes in the evolution of myths out of language.

(3.) The following is an abstract of Mr Müller's theory of one process by which myths were developed out of language. "The keenest eye of the antiquary and the philosopher" cannot see farther back, he says, than the period when expressions were coined for the most necessary ideas, and when a grammar began which was destitute of national peculiarities, but contained the germ of all the Turanian as well as the Aryan and Semitic forms of speech. This age Mr Müller calls the *Rhematic* period (*Sel. Ess.*, i. 306). (As yet there were no myths, or none alluded to by Mr Müller.) This was followed by an age in which at least two families of language, the Aryan and Semitic, left "the nomadic stage of grammar," and received once for all the peculiar impress of their formative system. There were as yet no such tongues as the Greek, Sanskrit, and Latin we know, only the Aryan speech from which these languages differentiated themselves. This was the *Dialectic* period. (As yet we understand that there were no myths, or none which Mr Müller takes into account.) We now come to the *Mythopœic* age. It was "half-way between the Dialectical period, presenting the human race gradually diverging into different families and languages, and the National period, exhibiting to us the earliest traces of nationalized language, and a nationalized literature in India, Persia, Greece, Italy, and Germany" (*op. cit.*, i. p. 311). The Mythopœic age, according to Mr Müller (*op. cit.*, i. 308), came *after* the "unavoidable divergence of dialects and languages," between that period and the age of "the establishment of laws and customs and the first beginnings of religion and poetry." Mr Müller's next step is to examine the intellectual and social conditions of man in the Mythopœic age. This he does by aid of philology. He analyses the *words* which, being common to Sanskrit, Greek, Latin, and German, must have existed in Aryan speech before the nations that talked these languages separated from the common stock. Although, as we have seen, the Mythopœic age came *before* "the earliest concentrations of political societies, the establishment of laws and customs," yet Mr Müller demonstrates that man, in the Mythopœic age, had political societies, and customs if not laws. Man, in the age called Mythopœic, the age when myths were made, already possessed the modern, or at all events the patriarchal, form of the family. His life was "half nomadic, half pastoral." He had abundance of domesticated animals, he practised agriculture, and had invented the plough. His political institutions included kingship. He was a builder of cities and a constructor of roads. He could weave, and work the metals, including iron. He possessed a system of decimal arithmetic, "which could only have been secured," says Mr Müller, "by the wear and tear of language in literary and practical use." Thus, as he possessed a literature, his language must have been tolerably definite and, so to say, stereotyped in meaning. "This earliest period, then, previous to any national separation, is what I call the Mythopœic period, for every one of these common Aryan words is, in a certain sense, a myth" (*op. cit.*, i. p. 355). It will be observed that, in the Mythopœic age, man was essentially civilized, and that his language had passed through "literary wear and tear."

(4.) Having thus defined the social, political, and literary status of men in the Mythopœic age, Mr Müller goes on to describe the style of their conversation, which in the long run was the source of their myths. In the language of that day (as we gather from an examination of Aryan words) a number of terms, which later became abstract, "expressed something substantial, something open to sensuous perceptions." "In ancient languages every one of these words" (such as "day," "night," "earth," "spring," "dawn") "had necessarily a termination expressive of gender, and this naturally produced the corresponding idea of sex, so that these names received not only an individual but a sexual character. . . . What must have been the result of this? As long as people thought in language it was simply impossible to speak of morning or evening, of spring and winter, without giving to these conceptions something of an individual, active, sexual, and at last personal character. They were either nothings, as they are nothings to our withered thought, or they were something; and then they could not be conceived as mere powers, but as beings powerful." Now let us take an example to show how, if the original sense of the names of those "powerful beings" were lost, while the names themselves survived in language as part of a traditional saying, a myth would arise where no myth was intended. Let us suppose that in the Mythopœic age some one said "the shining one pursues the burning one," meaning the sun follows the dawn. Let it further be supposed that the word for "shining one" was an Aryan prototype of the Greek ἥλιος, "the sun," and that the word for the "burning one" was, similarly, an Aryan prototype of the Sanskrit *ahana* or *dahana*, "the dawn." Then grant that the term for Helios came to be confused with Apollo (a god who has points in common with the sun), grant that the word for the "burning one" became, from something like *ahana* or *dahana*, *Daphne*, and admit that a certain tree was also called daphne, because its wood burned easily. When all these changes had happened and had been forgotten, Greeks would find in their language this expression, "Apollo pursues Daphne." They would see that "Apollo" was a masculine, "Daphne" a feminine, word. And they would thus be led to suppose that Apollo was a young amorous god who chased a fair reluctant nymph Daphne, and that Daphne, to avoid his pursuit, changed herself, or was changed, into a tree bearing the

same name.[1] "All this seems to me as clear as daylight," says Mr Müller.

So far two linguistic influences have been exhibited in their effect on mythology. One is the existence of gender terminations, producing in the human mind the belief that inanimate things spoken of as sexual must be sexual living powers. The other process (illustrated to some extent by the change of a phrase meaning "sunrise *follows* dawn" into "Phœbus *chases* Daphne") is the retention by a verb of its full original activity. The full theory of "auxiliary verbs" which originally possessed "a more material and expressive character" than they now retain will be found in *Selected Essays*, i. 365. Thus the Latin *fui*, "I was," corresponds to φύω, and in Greek "still shows its original and material power of growing." The theory is, then, that both substantives and auxiliary verbs "said more than they ought to say" in the Mythopœic age, and that this surplus of meaning, misunderstood, became the "Aberglaube," the irrational surplus of faith, in the myths.

(5.) The philological processes in the evolution of mythology are still unexhausted. It is plain that as long as every one knew that language "said more than it ought to say," as long as it was discounted and understood at its true value, it would not produce much mythology. "It is," says Mr Müller, "the essential character of a true myth that it should no longer be intelligible by a reference to spoken language." For the full development of myths, then, the old rich overweighted terms must have gone on existing, stereotyped in phrases, but their original significance must have ceased to be intelligible. But *how* did spoken language retain the words and the sayings, while it utterly lost their meaning? The process must be explained in the words of Mr Müller himself.

"Most nouns, as we have seen before, were originally appellatives or predicates expressive of what seemed at the moment the most characteristic attribute of an object. But as most objects have more than one attribute, and as, under different aspects, one or the other attribute might seem more appropriate to form the name, it happened by necessity that most objects during the early period of language had more than one name. In the course of time the greater number of these names became useless, and they were mostly replaced in literary languages by one fixed name, which might be called the proper name of such objects. The more ancient a language, the richer it is in synonyms. Synonyms, again, if used constantly, must naturally give rise to a number of homonyms. If we may call the sun by fifty names expressive of different qualities, some of these names will be applicable to other objects also, which would happen to possess the same quality. These different objects would then be called by the same name, they would become homonyms." (*Sel. Ess.*, i. 376-8.)

Thus, while one thing had many names, many things would have the same name. Again, "as the meanings of metaphors are forgotten, or the meanings of roots whence words were derived became dimmed and changed, many of these words would lose their radical as well as their poetical meaning. They would become mere names handed down in the conversation of a family; understood, perhaps, by the grandfather, familiar to the father, but strange to the son, and misunderstood by the grandson." As an example, Mr Müller gives Ζεύς, which, "originally a name of the sky, like the Sanskrit *Dyaus*," became gradually a proper name, which betrayed its appellative meaning only in a few proverbial expressions, such as Ζεὺς ὕει ("Zeus, or the sky, rains"), or *sub Jove frigido* ("under the chill air"). In this example, it is true, we have neither homonyms nor synonyms presented to us, nor do we see why the grandfather should have talked of the sky as a thing, while the grandson was driven to the inference that the sky was a person, and a very remarkable person too.

[1] This explanation of the myth of Daphne is compiled from *Selected Essays*, i. 398, 399, 607, 608. Meanwhile a well-known American Sanskrit scholar denies that *ahana* ever meant "dawn," or that it could become *dahana* and *daphne* by any philological process.

(6.) Mr Müller's next step is to collect illustrations of the processes he has described, and to adduce proofs that these processes really existed and acted. He looks for his proofs and his examples in Sanskrit poetry, in the poetry of the sacred hymns or *Vedas*. Here is his evidence for the action (in the Mythopœic age) of the processes he calls *synonymy* or *polyonymy* (many names for one thing) and *homonymy* (many things with one name):

"In the *Veda* the earth is called urvî (wide), prithvî (broad), mahî (great), and many more names of which the Nigantha mentions twenty-one. These twenty-one words would be synonyms. But urvî (wide) is not only given as a name of the earth, but also means a river. Prithvî (broad) means not only earth, but sky and dawn. Mahî (great, strong) is used for air and speech, as well as for earth. Hence earth, river, sky, dawn, air, and speech would become homonyms." (*Sel. Ess.*, i. 371.)

It will therefore be evident that, if the great-grandsons of the people of the Vedic age did not know whether their traditional expressions referred to earth, dawn, sky, air, or speech, confusions would arise, and from the confusions myths. Mr Müller ends by analysing and explaining some Greek stories.

We have now given as clear and distinct an account of Mr Müller's system of mythology as is possible within our limited space. It will be observed that the explanation applies to people speaking Indo-European languages, is grounded on a view of their early history as elucidated by philology, and on the whole resolves itself into this, that "mythology is a disease of language," a result of misunderstood phrases and of the gender-terminations of words. We now approach the criticism of Mr Müller's system, and our criticism will lead up to a new examination of the problem of mythology.

(1.) Mr Müller started with the wish to explain how the Greek poets, with their aversion to everything excessive or monstrous, came to ascribe the most abominable offences to their own gods. The gods were incestuous, were sinners of nameless sins. They disguised themselves in animal shapes; they tasted human flesh; they amused themselves with obscene jests; they died and were buried; they were born, and their birth-places were known. The first objection to Mr Müller's system is that it does not explain, but usually keeps clear of, the very horrors that need explanation. True, he easily shows that the sun can be regarded, now as the child, now as the bridegroom, of the dawn, and hence a story of incest may arise. The growing crop (to take an instance familiar to the early heathen apologists) may be regarded as the child of the showery sky, and again as its bride, and hence an unbecoming story, like the loves of Zeus and Persephone, might come to be credited. Once more, Zeus may be regarded as the father of all men, and hence the separate myths of his physical amours, whence spring the royal families of Hellas, might have originated. But, even if we accept all these explanations, we still must ask Mr Müller the questions which the early Christians asked the heathen expositors of and apologists for the myths. How are the disgusting details, the "savage, silly, and senseless" details, to be explained? Zeus is the heaven, and woos the earth, or the lower air, but why does he take the form of a bull or a cuckoo, why does he deceive Hera by celebrating a false marriage with a log of wood? Why does he try to expiate his amour with Demeter by his conduct to the ram? Why, when conceived of as the father of noble houses, does he adopt the shape of an ant, a swan, an eagle, a bull, a serpent? What mean the amours and animal metamorphoses of the other gods? Grant that Procris is the dew, as Mr Müller says it is, and how do you explain her unspeakable services to King Minos? Grant that Cronion only means "the ancient of days," and that, being misunderstood to mean "son of Cronus," the name gave

rise to the myth of Cronus, and how do you explain that god's mutilation of his father, and his habit of swallowing down alive each of his own children, whom he afterwards disgorged? Grant that Dionysus only means the vine and its influence, and how do you explain his unspeakable conduct as recorded in the mysteries at Halimus in Attica? How, in short, as Arnobius asked the heathen, how, if the myths represent pure natural facts and phenomena, do they come to be crowded with the obscene details which disgusted philosophers six hundred years before Christ? In what stage of society did this "impure way of stating pure facts" win favour? Mr Müller must fix the period at which such details were invented, some time between his Mythopœic age and the age of Xenophanes and Theagenes. In the meantime his system does not explain and scarcely touches on the very facts that most call for explanation. Why did the Greek poets relate divine myths of which we find the parallels "among the lowest tribes of Africa and America"?

(2.) Mr Müller's system is a result of the philological discoveries that establish the linguistic unity of the Indo-European peoples, and is founded on an analysis of their language. But myths precisely similar in irrational and repulsive character to those of the Aryan races exist among Australians, South Sea Islanders, Eskimo, Bushmen in Africa, among Solomon Islanders, Iroquois, and so forth. The facts being identical, an identical explanation should be sought, and, as the languages in which the myths exist are essentially different, an explanation founded on the Aryan language is likely to prove too narrow. Mr Müller indeed, has ventured into Finnish philology and mythology, but a wider examination is needed. Once more, even if we discover the original meaning of a god's name, it does not follow that we can explain by aid of the significance of the name the myths about the god. For nothing is more common than the attraction of a more ancient story into the legend of a later god or hero. Myths of unknown antiquity, for example, have been attracted into the legend of Charlemagne, just as the *bons mots* of old wits are transferred to living humorists. Therefore, though we may ascertain that Zeus means "sky" and Agni "fire," we cannot assert, with Mr Müller, that all the myths about Agni and Zeus were originally told of fire and sky. When these gods became popular they would inevitably inherit any current exploits of earlier heroes or gods. These exploits would therefore be explained erroneously if regarded as originally myths of sky or fire. We cannot convert Mr Müller's proposition "there was nothing told of the sky that could not in some form or other be ascribed to Zeus" into "there was nothing ascribed to Zeus that had not at some time or other been told of the sky." This is also, perhaps, the proper place to observe that names derived from natural phenomena—sky, clouds, dawn, and sun—are habitually assigned by Brazilians, Ojibways, Australians, and other savages to living men and women. Thus the story originally told of a man or woman bearing the name "sun," "dawn," "cloud," may be mixed up later with myths about the real celestial dawn, cloud, or sun. For all these reasons the information obtained from philological analysis of names is to be distrusted. We must also bear in mind that early men when they conceived, and savage men when they conceive, of the sun, moon, wind, earth, sky, and so forth, have no such ideas in their minds as we attach to these names. They think of sun, moon, wind, earth, and sky as of living human beings with bodily parts and passions. Thus, even when we discover an elemental meaning in a god's name, that meaning may be all unlike what the word suggests to civilized men. A final objection is that philologists differ widely as to the true analysis and real meaning of the divine names. Mr Müller, for example, connects κρόνος with χρόνος, "time"; Preller with κραίνω, "I fulfil," and so forth.

(3.) The objection to Mr Müller's doctrine of the Rhematic and Dialectic periods of language as bearing on mythology is that he either supposes man to have had no myths in these periods, or takes no account of the myths they may have had. Yet it is certain, and admitted by himself, that we do find myths in languages of all known sorts. If man on his way to being Aryan or Semitic, if man in the Rhematic and Dialectic stages, possessed no myths, he must have differed from all men of whom we know anything. If he did possess myths these cannot have been produced by the conditions of Mr Müller's Mythopœic age, because that age had not yet been reached. And if man in the Rhematic and Dialectic periods had myths, and if they survived into the Mythopœic and later periods, they cannot be explained by Mr Müller's Mythopœic theory. Especially if these earlier myths crystallized round a god or hero of later date will the effort to explain the earlier stories by analysis of the later names be fruitless. As to the Mythopœic period itself, as described by Mr Müller, it was rather an age when the materials for myths were accumulated than when myths themselves were developed.

(4.) Mr Müller attempts to show how the conversation of men in the Mythopœic age became the source of myths. Here he is endeavouring, really, to account for that universal attribution of life, sex, action, and thought to all phenomena which is, indubitably, the essential condition of mythology. He explains this "animism" as an erroneous condition of thought into which men essentially civilized were driven by the nature of language. In language all words denoted *gender*, hence (he thinks) men were led to suppose that gender and sex, with all that follows, were possessed by all objects. But it is scarcely necessary to reply (the truth being so obvious) that the gender-terminations of words reflected, and must have arisen from, a state of the human intellect in which all things were regarded as persons. The civilized men of the Mythopœic age were not compelled, as Mr Müller thinks, to believe that all phenomena were persons, because the words which denoted the phenomena had gender-terminations. On the other hand, the gender-terminations were survivals from an early stage of thought in which personal characteristics, including sex, had been attributed to all phenomena. This condition of thought is demonstrated to be, and to have been, universal among savages, and it may notoriously be observed among children. Mr Müller explains it as the result of reflexions on gender-terminations, but how does he explain these terminations themselves? His theory is that, somehow, gender-terminations arose in language. Then, when they had become a tradition of language, they "reacted on the mind with irresistible power," and men, who had previously been as sensible as ourselves, felt themselves obliged to animate and personify all phenomena. Mr Müller remarks "there is some truth in this," (that is, in the contention that a belief in the personal character of phenomena reflected itself in gender-terminations), "but it only serves to confirm the right view of the influence of language on thought, for this tendency, though in its origin intentional, and therefore the result of thought, became soon a mere rule of tradition in language, and then it reacted on the mind with irresistible power" (*Sel. Ess.*, i. 604). Mr Müller thinks that men first held nature to be animated and personal. This belief reflected itself in language, but it (apparently) produced no myths. In a later and civilized age language brought back the old state of intellect, and myths were produced. This becomes a superfluous hypothesis of degradation, for the original state

of intellect was enough for the genesis of myths, without the conjectured reaction of language.

(5.) The elaborate theory of the persistence of phrases without meaning in language is inconsistent with all that Mr Muller has told us about the civilization of Mythopœic man. He belonged to a settled society, with a literature of its own. No proof is given that men so advanced in civilization would forget the meanings of ordinary phrases and yet *retain* the phrases in their language. How could a society with such shifting speech develop "by literary wear and tear" *a system of decimal arithmetic?* But Mr Müller says that the rapid process of oblivion which begat myths might occur in four generations.

(6.) Again, no proof is given of the existence of the processes called homonymy and polyonymy. Mr Müller, by way of proof, quotes the *Vedas*,—artificial poems produced in a language which did not even exist in what he calls the Mythopœic age. An Englishman might as well illustrate the conversation of his ancestors by examples chosen from *Hymns Ancient and Modern.* Mr Müller gives instances of homonymy and polyonymy in the *Vedas*, but he does not show that *these processes made it impossible for* the descendants of the Vedic poets to know what they were talking about. He says the descendants of Mythopœic men did not know what their traditional phrases meant, but he advances no proof that Mythopœic men used the processes called homonymy and polyonymy. Finally, when he looks for illustrations, he finds them, not in the Mythopœic period at all, but in the established national languages of the Greeks and of the Aryans of India. And in these illustrations the very points which most demand explanation—the "silly, senseless, and savage" details—are left not only unexplained but almost untouched. Thus Mr Müller's theory that myths are "a disease of language" seems destitute of evidence, and inconsistent with what is historically known about the relations between the language and the social, political, and literary condition of men.

Theory of Mr Herbert Spencer.—The system of Mr Herbert Spencer, as explained in *Principles of Sociology*, has many points in common with that of Mr Müller. Mr Spencer attempts to account for the state of mind (the foundation of myths) in which man personifies and animates all phenomena. According to his theory, too, this habit of mind may be regarded as the result of degeneration, for in his view, as in Mr Müller's, it is not primary, but the result of misconceptions. But, while language is the chief cause of misconceptions with Mr Muller, with Mr Spencer it is only one of several forces all working to the same result. Statements which originally had a different significance are misinterpreted, he thinks, and names of human beings are also misinterpreted in such a manner that early races are gradually led to believe in the personality of phenomena. He too notes "the defect in early speech"—that is, the "lack of words free from implications of vitality"—as one of the causes which "favour personalization." Here, of course, we have to ask Mr Spencer, as we asked Mr Müller, *why* words in early languages "imply vitality." These words must reflect the thought of the men who use them before they react upon that thought and confirm it in its misconceptions. So far Mr Spencer seems at one with the philological school of mythologists, but he warns us that the misconstructions of language in his system are "different in kind, and the erroneous course of thought is opposite in direction." According to Mr Spencer (and his premises, at least, are correct), the names of human beings in an early state of society are derived from incidents of the moment, and often refer to the period of the day, or the nature of the weather. We find, among Australian natives, among Abipones in South America, and among Ojibways in the North, actual people named Dawn, Gold Flower of Day, Dark Cloud, Sun, and so forth. Mr Spencer's argument is that, given a story about real people so named, in process of time and forgetfulness the anecdote which was once current about a man named Storm and a woman named Sunshine will be transferred to the meteorological phenomena of sun and tempest. Thus these purely natural agents will come to be "personalized" (*Prin. Soc.*, 392), and to be credited with purely human origin and human adventures. Another misconception would arise when men had a tradition that they came to their actual seats from this mountain, or that lake or river, or from lands across the sea. They will mistake this tradition of local origin for one of actual parentage, and will come to believe that, like certain Homeric heroes, they are the sons of a river (now personified), or of a mountain, or, like a tribe mentioned by Garcilasso de la Vega, that they are descended from the sea. Once more, if their old legend told them that they came from the rising sun, they will hold, like many races, that they are actually the children of the sun. By this process of forgetfulness and misinterpretation, *mountains, rivers, lakes, sun, and sea would receive human* attributes, while men would degenerate from a more sensible condition into a belief in the personality and vitality of inanimate objects. As Mr Spencer thinks ancestor-worship the first form of religion, and as he holds that persons with such names as sun, moon, and the like became worshipped as ancestors, his theory results in the belief that nature-worship and the myths about natural phenomena—dawn, wind, sky, night, and the rest—are a kind of transmuted worship of ancestors and transmuted myths about real men and women. "Partly by confounding the parentage of the race with a conspicuous object marking the natal region of the race, partly by literal interpretation of birth names, and partly by literal interpretation of names given in eulogy" (such as Sun and Bull, among the Egyptian kings), and also through "implicit belief in the statements of forefathers," there has been produced belief in descent from mountains, sea, dawn, from animals which have become constellations, and from persons once on earth who now appear as sun and moon. A very common class of myths assures us that certain stocks of men are descended from beasts, or from gods in the shape of beasts. Mr Spencer explains these by the theory that the remembered ancestor of a stock had, as savages often have, an animal name, as Bear, Wolf, Coyote, or what not. In time his descendants came to forget that the name was a mere name, and were misled into the opinion that they were children of a real coyote, wolf, or bear. This idea, once current, would naturally stimulate and diffuse the belief that such descents were possible, and that the animals are closely akin to men.

The chief objection to these processes is that they require, as a necessary condition, a singular amount of memory on the one hand and of forgetfulness on the other. The lowest contemporary savages remember little or nothing of any ancestor farther back than the grandfather. But men in Mr Spencer's Mythopœic age had much longer memories On the other hand, the most ordinary savage does not misunderstand so universal a custom as the imposition of names peculiar to animals or derived from atmospheric phenomena. He calls his own child Dawn or Cloud, his own name is Sitting Bull or Running Wolf, and he is not tempted to explain his great-grandfather's name of Bright Sun or Lively Raccoon on the hypothesis that the ancestor really was a raccoon or the sun. Moreover, savages do not worship ancestresses or retain lively memories of their great-grandmothers, yet it is through the female line in the majority of cases that the animal or other ancestral name is derived. The son of an Australian whose family

name is Crane takes his mother's name, Swan or Cockatoo, or whatever it may be, and the same is the general rule in Africa and America among races who rarely remember their great-grandfathers. On the whole, then (though degeneracy, as well as progress, is a force in human evolution), we are not tempted to believe in so strange a combination of forgetfulness with long memory, nor so excessive a degeneration from common sense into a belief in the personality of phenomena, as are required no less by Mr Spencer's system than by that of Mr Müller.

A New Examination of Mythologies.—We have stated and criticized the more prominent modern theories of mythology. It is now necessary first to recapitulate the chief points in the problem, and then to attempt to explain them by a comparison of the myths of various races. The difficulty of mythology is to account for the following among other apparently irrational elements in myths: the wild and senseless stories of the beginnings of things, of the origin of men, sun, stars, animals, death, and the world in general; the infamous and absurd adventures of the gods; why divine beings are regarded as incestuous, adulterous, murderous, thievish, cruel, cannibals, and addicted to wearing the shapes of animals; the myths of metamorphosis into plants, beasts, and stars; the repulsive stories of the state of the dead; the descents of the gods into the place of the dead, and their return thence. It is extremely difficult to keep these different categories of myths separate from each other. If we investigate myths of the origin of the world, we often find gods in animal form active in the work of world-making. If we examine myths of human descent from animals, we find gods busy there, and if we try to investigate the myths of the origin of the gods, the subject gets mixed up with the mythical origins of things in general.

Our first question will be, Is there any stage of human society, and of the human intellect, in which facts that appear to us to be monstrous and irrational are accepted as ordinary occurrences of every-day life? Mr Lane, in his preface to the *Arabian Nights*, says that the Arabs have an advantage over us as story-tellers. They can introduce such incidents as the change of a man into a horse, or of a woman into a dog, or the intervention of an *afreet*, without any more scruple than our own novelists feel in describing a duel or the concealment of a will. Among the Arabs the actions of magic and of spirits are regarded as at least as probable and common as duels and concealments of wills in European society. It is obvious that we need look no farther for the explanation of the supernatural events in Arab romances. Now let us apply this system to mythology. It is admitted that Greeks, Romans, Aryans of India in the age of the Sanskrit commentators, Egyptians of the Ptolemaic and earlier ages, were as much puzzled as we are by the mythical adventures of their gods. But is there any known stage of the human intellect in which these divine adventures, and the metamorphoses of men into animals, trees, stars, and converse with the dead, and all else that puzzles us in the civilized mythologies, are regarded as possible incidents of daily human life? Our answer is that everything in the civilized mythologies which we regard as irrational seems only part of the accepted and rational order of things to contemporary savages, and in the past seemed equally rational and natural to savages concerning whom we have historical information. Our theory is, therefore, that the savage and senseless element in mythology is, for the most part, a legacy from ancestors of the civilized races who were in an intellectual state not higher than that of Australians, Bushmen, Red Indians, the lower races of South America, and other worse than barbaric peoples. As the ancestors of the Greeks, Aryans of India, Egyptians, and others advanced in civilization, their religious thought was shocked and surprised by myths (originally dating from the period of savagery, and natural in that period) which were preserved down to the time of Pausanias by local priesthoods, or which were stereotyped in the ancient poems of Hesiod and Homer, or in the *Brahmanas* and *Vedas* of India, or were retained in the popular religion of Egypt. This theory recommended itself to Lobeck. "We may believe that ancient and early tribes framed gods like themselves in action and in experience, and that the allegorical element in myths is the addition of later peoples who had attained to purer ideas of divinity, yet dared not reject the religion of their ancestors" (*Aglaoph.*, i. 153). The senseless element in the myths would by this theory be for the most part a "survival." And the age and condition of human thought from which it survived would be one in which our most ordinary ideas about the nature of things and the limits of possibility did not yet exist, when all things were conceived of in quite other fashion,—the age, that is, of savagery. It is universally admitted that "survivals" of this kind do account for many anomalies in our institutions, in law, politics, society, even in dress and manners. If isolated fragments of an earlier age abide in these, it is still more probable that other fragments will survive in anything so closely connected as mythology with the conservative religious sentiment. Again, if this view of mythology can be proved, much will have been done to explain a problem which we have not yet touched, namely, *the distribution of myths*. The science of mythology has to account, if it can, not only for the existence of certain stories in the legends of certain races, but also for the presence of stories practically the same among almost all races. In the long history of mankind it is impossible to deny that stories may conceivably have spread from a single centre, and been handed on from races like the Indo-European and the Semitic to races as far removed from them in every way as the Zulus, the Australians, the Eskimo, the natives of the South Sea Islands. But, while the possibility of the diffusion of myths by borrowing and transmission must be allowed for, the hypothesis of the origin of myths in the savage state of the intellect supplies a ready explanation of their wide diffusion. Archæologists are acquainted with objects of early art and craftsmanship, rude clay pipkins and stone weapons, which can only be classed as "human," and which do not bear much impress of any one national taste and skill. Many myths may be called "human" in this sense. They are the rough products of the early human mind, and are not yet characterized by the differentiations of race and culture. Such myths might spring up anywhere among untutored men, and anywhere might survive into civilized literature. Therefore where such myths are found among Greeks, Australians, Egyptians, Mangaians, and others it is unnecessary to account for their wide diffusion by any hypothesis of borrowing, early or late. The Greek "key" pattern found on objects in Peruvian graves was not necessarily borrowed from Greece, nor did Greeks necessarily borrow from Aztecs the "wave" pattern which is common to both. The same explanation may be applied to Greek and Aztec myths of the deluge, to Australian and Greek myths of the original theft of fire. Borrowed they may have been, but they may as probably have been independent inventions. It is true that some philologists (among others Professor Sayce) deprecate as unscientific the comparison of myths which are found in languages not connected with each other. The objection rests on the theory that myths are a disease of language, a morbid offshoot of language, and that the legends in unconnected languages must therefore be kept apart. But, as the theory which we are explaining does

not admit that *language* is more than a subordinate cause in the development of myths, as it seeks for the origin of myths in a given condition of *thought* through which all races have passed, we need do no more than record the objection of Professor Sayce. Our next step must be briefly to examine the intellectual condition of savages, that is, of races varying from the condition of the Andaman islanders to that of the Solomon Islanders and the ruder Red Men of the American continent.

The Intellectual Condition of Savages. Nature of our Evidence.—In a developed treatise on the subject of mythology it would be necessary to criticize, with a minuteness which is impossible here, our evidence for the very peculiar mental condition of the lower races. Mr Max Müller has asked (when speaking of the mental condition of men when myths were developed), "was there a period of temporary madness through which the human mind had to pass, and was it a madness identically the same in the south of India and the north of Iceland?" To this we may answer that the human mind had to pass through the savage stage of thought, that this stage was for all practical purposes "identically the same" everywhere, and that to civilized observers it does resemble "a temporary madness." Many races are still abandoned to that temporary madness; many others which have escaped from it were observed and described while still labouring under its delusions. Our evidence for the intellectual ideas of man in the period of savagery we derive partly from the reports of voyagers, historians, missionaries, partly from an examination of the customs, institutions, and laws in which the lower races gave expression to their notions. As to the first kind of evidence, we must be on our guard against several sources of error. Where religion is concerned, travellers in general and missionaries in particular are biased in several distinct ways. The missionary is sometimes anxious to prove that religion can only come by revelation, and that certain tribes, having received no revelation, have no religion or religious myths at all. Sometimes the missionary, on the other hand, is anxious to demonstrate that the myths of his heathen flock are a corrupted version of the Biblical narrative. In the former case he neglects the study of savage myths; in the latter he unconsciously accommodates what he hears to what he calls "the truth." The traveller who is not a missionary may either have the same prejudices, or he may be a sceptic about revealed religion. In the latter case he is perhaps unconsciously moved to put burlesque versions of Biblical stories into the mouths of his native informants, or to represent the savages as ridiculing the Seriptural traditions which he communicates to them. Yet again we must remember that the leading questions of a European inquirer may furnish a savage with a thread on which to string answers which the questions themselves have suggested. "Have you ever had a great flood?" "Yes." "Was any one saved?" The question starts the invention of the savage on a deluge-myth, of which, perhaps, the idea has never before entered his mind. There still remain the difficulties of all conversation between civilized men and unsophisticated savages, the tendency to hoax, and other sources of error and confusion. In receiving this kind of evidence, then, we need to know the character of our informant, his means of communicating with the heathen, his power of testing evidence, and his good faith. His testimony will have additional weight if supported by the "undesigned coincidences" of other evidence, ancient and modern. If Strabo and Herodotus and Pomponius Mela, for example, describe a custom, rite, or strange notion in the Old World, and if mariners and missionaries find the same notion or custom or rite in Polynesia or Australia or Kamchatka, we can scarcely doubt the truth of the reports. The evidence is best when given by ignorant men, who are astonished at meeting with an institution which ethnologists are familiar with in other parts of the world. Another method of obtaining evidence is by the comparative study of savage laws and institutions. Thus we find in Asia, Africa, America, and Australia that the marriage laws of the lower races are based on a belief in kinship with animals. The evidence for this belief is thus entirely beyond suspicion. We find, too, that political power, sway, and social influence are based on the ideas of magic, of metamorphosis, and of the power which certain men possess to talk with the dead and to visit the abodes of death. All these ideas are the stuff of which myths are made, and the evidence of savage institutions, in every part of the world, proves that these ideas are the universal inheritance of savages. As to the quantity of evidence, it is actually overpowering in amount.

Savage Ideas about the World.—We all "move about in worlds not realized," though science is constantly occupied in winning over more material from the chaos of the unknown to the realm of rational knowledge. Savage men are like ourselves in curiosity and anxiety *causas cognoscere rerum*, but with our curiosity they do not possess our powers of attention. They are as easily satisfied with an explanation of phenomena as they are eager to possess an explanation. Inevitably they furnish themselves with their philosophy out of their scanty stock of acquired ideas, and these ideas and general conceptions seem almost imbecile to civilized men. Curiosity and credulity, then, are the characteristics of the savage intellect. When a phenomenon presents itself the savage requires an explanation, and that explanation he makes for himself, or receives from tradition, in the shape of a *myth*. The basis of these myths, which are just as much a part of early conjectural science as of early religion, is naturally the experience of the savage *as construed by himself.* Man's craving to know "the reason why" is already "among rude savages an intellectual appetite," and "even to the Australian scientific speculation has its germ in actual experience."[1] How does he try to satisfy this craving? Mr Tylor replies, "When the attention of a man in the myth-making stage of intellect is drawn to any phenomenon or custom which has to him no obvious reason, he invents and tells a story to account for it." Against this statement it has been urged that men in the lower stages of culture are not curious, but take all phenomena for granted. If there were no direct evidence in favour of Mr Tylor's opinion, it would be enough to point to the nature of savage myths themselves. It is not arguing in a circle to point out that almost all of them are nothing more than explanations of intellectual difficulties, answers to the question, How came this or that phenomenon to be what it is? Thus savage myths answer the questions,—What was the origin of the world, and of men, and of beasts? How came the stars by their arrangement and movements? How are the motions of sun and moon to be accounted for? Why has this tree a red flower, and this bird a black mark on the tail? What was the origin of the tribal dances, or of this or that law of custom or etiquette? Savage mythology, which is also savage science, has a reply to all these and all similar questions, and that reply is always found in the shape of a story. The answers cannot be accounted for without the previous existence of the questions.

We have now shown how savages come to have a mythology. It is their way of satisfying the early form of scientific curiosity, their way of realizing the world in which they move. But they frame their stories, necessarily and naturally, in harmony with their general theory

[1] Tylor, *Primitive Culture*, i. 369, 1871.

of things, with what we may call "savage metaphysics." Now early man, as Mr Müller says, "not only did not think as we think, but did not think as we suppose he ought to have thought." The chief distinction between his mode of conceiving the world and ours is his vast extension of the theory of personality. The history of thought is the history of the process of narrowing the range and intensifying the conception of personality. To civilized man only human beings seem personal. We scarcely regard each of the more intelligent lower creatures as "an I," and we can hardly be said to attribute definite personality at all to the less intelligent creatures, such as fishes. It is only by the half-conscious survival of older thought in poetry that we attribute personality to the sun or the wind, or say, "at one stride comes the Dark." But to the savage, and apparently to men more backward than the most backward peoples we know, all nature was a congeries of animated personalities. The savage's notion of personality is more a universally diffused feeling than a reasoned conception, and this feeling of a personal self he impartially distributes all over the world as known to him. One of the Jesuit missionaries in North America thus describes the Red Man's philosophy:[1] "Les sauvages se persuadent que non seulement les hommes et les autres animaux, mais aussi que toutes les autres choses sont animées." Crevaux, in the Andes, found that the Indians believed that the beasts have *piays* (sorcerers and doctors) like themselves.[2] This opinion we may name *personalism*, and it is the necessary condition of savage (and, as will be seen, of civilized) mythology. The Jesuits could not understand how spherical bodies like sun and moon could be mistaken for human beings. Their catechumens put them off with the answer that the drawn bows of the heavenly bodies gave them their round appearance. "The wind was formerly a person; he became a bird," say the Bushmen, and *g'ōō ka ! kai*, a respectable Bushman once saw the personal wind at Haarfontein.[3] The Egyptians, according to Herodotus (iii. 16), believed fire to be *θηρίον ἔμψυχον*, a live beast. The Bushman who saw the Wind meant to throw a stone at it, but it ran into a hill. From the wind as a person the Bhinyas in India (Dalton, p. 140) claim descent, and in Indian epic tradition the leader of the ape army was a son of the wind. The Wind, by certain mares, became the father of wind-swift steeds mentioned in the *Iliad*. The loves of Boreas are well known. These are examples of the animistic theory applied to what, in our minds, seems one of the least personal of natural phenomena. The sky (which appears to us even less personal) has been regarded as a personal being by Samoyeds, Red Indians, Zulus,[4] and traces of this belief survive in Chinese, Greek, and Roman religion.

Thus the savage mind regards even the most abstract phenomena as persons, with human parts and passions. This idea alone will account for much that is strange in

the same opinion of the personality and human character of all animals. "Ils tiennent les poissons raisonnables, comme aussi les cerfs," says a Jesuit father about the North-American Indians (*Relations, loc. cit.*). In Australia the natives believe that the wild dog has the power of speech, like the cat of the Coverley witch in the *Spectator*. The Breton peasants, according to M. Sébillot, credit all birds with language, which they even attempt to interpret. The old English and the Arab superstitions about the language of beasts are examples of this opinion surviving among civilized races. The bear in Norway is regarded as almost a man, and his dead body is addressed and his wrath deprecated by Samoyeds and Red Indians. "The native bear *Kur-bo-roo* is the sage counsellor of the aborigines in all their difficulties. When bent on a dangerous expedition, the men will seek help from this clumsy creature, but in what way his opinions are made known is nowhere recorded."[5] Schoolcraft mentions a Red Indian story explaining how "the bear does not die," but this tale Mr Schoolcraft (like Herodotus in Egypt) "cannot bring himself to relate." He also gives examples of Iowas conversing with serpents. These may serve as examples of the savage belief in the human intelligence of animals. Man is on an even footing with them, and with them can interchange his ideas. But savages carry this opinion much further. Man in their view is actually, and in no figurative sense, akin to the beasts. Certain tribes in Java "believe that women when delivered of a child are frequently delivered at the same time of a young crocodile."[6] The common European story of a queen accused of giving birth to puppies shows the survival of the belief in the possibility of such births among civilized races, while the Aztecs had the idea that women who saw the moon in certain circumstances would produce mice. But the chief evidence for the savage theory of man's close kinship with the lower animals is found in the institution called *totemism*. This is not the place to discuss totemism in all its bearings. It is, roughly speaking, the belief that certain stocks of men in the various tribes are descended by blood descent from certain objects animate or inanimate, but especially from beasts. The strength of the opinion is proved by its connexion with very stringent marriage laws. No man (according to the rigour of the custom) may marry a woman who bears the same family name as himself, that is, who is descended from the same inanimate object or animal. Nor may people (if they can possibly avoid it) eat the flesh of animals who are their kindred. We have only space to indicate briefly here the wide diffusion of this extraordinary belief. Among the Murri, or natives of Australia, the local tribes are divided into stocks which may not intermarry, and which regard themselves as being descended from kangaroos, cockatoos, emus, pelicans, and other animals. A man and a woman who both claim descent from the same animal consider themselves as "of one flesh," brother and sister in the emu or kangaroo stock, and therefore may not intermarry (Dawson, p. 26). As the cannibals of New Caledonia do not eat their own tribesmen, so these stocks abstain from the flesh of their animal tribe-fellow. The Australians have a still more curious division of all nature into groups of kindred, so that one man may be descended, indeed, from the fish-hawk, but he also counts cousins with smoke and the honeysuckle tree. Again, the kangaroo and men-kangaroos are akin to summer, the wind, and the shevak tree. "The South Australian savage looks upon the world as the Great Tribe, to one of whose divisions he himself belongs, and all things, animate or inanimate, which belong to his class are parts of the body corporate

[6] Hawkesworth, *Voyages*, iii. 756.

whereof he himself is part."[1] Turning from Australia to the west coast of Africa, we find similar ideas prevailing there. Among the Ashantees, as among the Australians, there are local divisions of the people, through which are scattered stocks claiming descent from animals, plants, and other natural objects.[2] As in Australia, the families may not eat the animals to which they are akin. The same notions prevail among the Basutos and other African tribes.[3] In America the amount of evidence for similar institutions grounded on similar creeds is too large to be dealt with here. The old missionaries, as Charlevoix and Bancroft, the old historian of the Peruvian tribes, Garcilasso de la Vega, the travels of Franklin, the collections of Bancroft and Schoolcraft, bear irrefutable testimony to the American belief in descent from animals and from inanimate objects, the kinship being recognized, as in Australia, by marriage laws of the strictest character. In India the idea of animal kinship is just as powerful as elsewhere.[4] The Hos and Mundas exhibit this creed in their marriage law. "The Mundaris, like the Oraons, adopt as their tribal distinction the name of some animal, and the flesh of that animal is tabooed to them as food; for example, the eel and the tortoise" (Dalton, pp. 189, 254). Turner describes analogous institutions in his *Polynesia* (p. 196). The Samoans, like the Egyptians, refuse to eat their own tribal gods, but consume those of their neighbours. Siberian examples are given in Sir John Lubbock's *Origin of Civilization*, under the head of the Jakuts. Among the Bonis (negroes relapsed into savagery out of slavery in Cayenne) one family reveres the red ape, another the cayman, a third the turtle.[5] The higher religion of the Bonis is a survival of Christianity. The language is a mixture of English, Dutch, and Creole patois. These instances from almost every quarter of the globe, from Siberia to Peru, from Bengal to Canada, from Ashantee to the Cape, will suffice to indicate the strength and wide diffusion of the savage belief in animal kinship with men. Considerable proof of the survival of this sentiment among the Semitic races is given by Professor Robertson Smith in "Animal Worship and Animal Tribes among the Arabs and in the Old Testament," *Journal of Philology*, vol. ix. No. 17.[6]

Savage man, then, regards all objects as animate and personal, and himself as physically akin to plants, animals, and other animate and inanimate things. He also believes that many of his own tribe-fellows have the power of assuming the shapes of animals, and that the souls of his dead kinsfolk revert to animal forms. Sir A. C. Lyall, writing from Hindustan, observes that "to those who live in a country where wicked people and witches are constantly taking the form of wild beasts the explanation of lycanthropy by a confusion between λευκός (white) and λύκος (a wolf) seems wanton." Our sense of the wantonness and inadequacy of this etymological explanation is increased when we find phenomena like LYCANTHROPY (*q. v.*) believed in everywhere, whatever the language spoken by the believers. Mr Lane, in his introduction to the *Arabian Nights* (i. p. 58), says he found the belief in these transmigrations accepted solemnly in Cairo. Bancroft brings evidence to prove that the Mexicans supposed pregnant women would turn into beasts, and sleeping children into mice, if things went wrong in the ritual of a certain solemn sacrifice. There is a well-known Scotch legend to the effect that a certain old witch was once fired at in her shape as a hare, and that where the hare was hit there the old woman was found to be wounded. Lafitau tells the same story as current among his Red Indian flock, except that the old witch and her son took the form of birds, not of hares. A Scandinavian witch does the same in the Egil saga. In Lafitau's tale the birds were wounded by the magic arrows of a medicine man, and the arrow-heads were found in the bodies of the human culprits. In Japan[7] people chiefly transform themselves into badgers. The sorcerers of Honduras (Bancroft, i. 740) "possessed the power of transforming men into wild beasts." Regnard, the French dramatist, found in Lapland (1681) that witches could turn men into cats, and could themselves assume the forms of swans, crows, falcons, and geese. Among the Bushmen[8] "sorcerers assume the form of beasts and jackals." Dobrizhofer, a missionary in Paraguay (1717-1791), learned that "sorcerers arrogate to themselves the power of changing men into tigers" (Eng. transl., i. p. 63). He was present at a conversion of this sort, though the miracle beheld by the people was invisible to the missionary. Near Loanda Livingstone noted that "a chief may metamorphose himself into a lion, kill any one he chooses, and resume his proper form." The same accomplishments distinguish the Barotse and Balonda.[9] Among the Mayas of Central America sorcerers could transform themselves "into dogs, pigs, and other animals; their glance was death to a victim" (Bancroft, ii. 797). The Thlinkeets hold that their shamans have the same powers.[10] A bamboo in Sarawak is known to have been a man. Metamorphoses into stones are as common among Red Indians and Australians as in Greek mythology. Compare the cases of Niobe and the victims of the Gorgon's head.[11] Zulus, Red Indians, Aztecs,[12] Andaman Islanders, and other races believe that their dead assume the shapes of serpents and of other creatures, often reverting to the form of the animal from which they originally descended. In ancient Egypt "the usual prayers demand for the deceased the power of going and coming from and to everywhere *under any form they like*."[13] A trace of this opinion may be noticed in the *Æneid*. The serpent that appeared at the sacrifice of Æneas was regarded as possibly a "manifestation" of the soul of Anchises (*Æneid*, v. 84)—

> "Dixerat hæc, adytis quum lubricus anguis ab imis
> Septem ingens gyros, septena volumina, traxit,"

and Æneas is

> "Incertus, Geniumne loci, famulumne parentis
> Esse putet."

On the death of Plotinus, as he gave up the ghost, a snake glided from under his bed into a hole in the wall.[14] Compare Pliny[15] on the cave "in quo manes Scipionis Africani majoris custodire draco dicitur."

Without further investigating the survivals of these ideas among civilized races (the most notorious examples are the Indian and Pythagorean theories of transmigration), enough has been said to prove the savage belief in man's kinship with the animals and its survival in civilization. The last peculiarity in savage philosophy to which we need call attention here is the belief in spirits and in human intercourse with the shades of the dead. The topic has been

so exhaustively treated by Mr Tylor in his *Primitive Culture*, and the evidence so fully set forth, that we need do little more than set on record the general facts. With the savage natural death is not a universal and inevitable ordinance. "All men must die" is a generalization which he has scarcely reached; in his philosophy the proposition is more like this, "all men who die die by violence." A natural death is explained as the result of a sorcerer's spiritual violence, and the disease is attributed to magic, or to the action of hostile spirits. After death the man survives as a spirit, sometimes taking an animal form, sometimes invisible, sometimes to be observed "in his habit as he lived." As to the origin of the belief in the continued existence and activity of the dead, the current theories will be found in the article Apparitions. The philosophy is shortly put in the speech of Achilles (*Iliad*, xxiii. 103) after he has beheld the dead Patroclus in a dream: "Ay me, there remaineth then even in the house of Hades a spirit and phantom of the dead, *for* all night long hath the ghost of hapless Patroclus stood over me, wailing and making moan." It is almost superfluous to quote here the voluminous evidence for the intercourse with spirits which savage chiefs and medicine men are believed to maintain. They can call up ghosts, or can go to the ghosts, in Australia, New Caledonia, New Zealand, North America, Zulu-land, among the Eskimo, and generally in every quarter of the globe. The men who enjoy this power are the same as they who can change themselves and others into animals. They too command the weather, and, says an old French missionary, "are regarded as very Jupiters, having in their hands the lightning and the thunder" (*Relations, loc. cit.*). They make good or bad seasons, and control the vast animals who, among ancient Persians and Aryans of India, as among Zulus and Iroquois, are supposed to grant or withhold the rain, and to thunder with their enormous wings in the region of the clouds.

We are now in a position to sum up the ideas of savages about man's relations to the world. We started on this inquiry because we found that savages regarded sky, wind, sun, earth, and so forth as practically men, and we had then to ask, what sort of men, men with what powers? The result of our examination, so far, is that in savage opinion sky, wind, sun, sea, and many other phenomena have, being personal, all the powers attributed to real human persons. These powers and qualities are—(1) relationship to animals and ability to be transformed and to transform others into animals and other objects; (2) magical accomplishments, as—(*a*) power to visit or to procure the visits of the dead, (*b*) other magical powers, such as control over the weather.

Once more, the great forces of nature, considered as persons, are involved in that inextricable confusion in which men, beasts, plants, stones, stars, are all on one level of personality and animated existence. This is the philosophy of savage life, and it is on these principles that the savage constructs his myths, while these, again, are all the scientific explanations of the universe with which he has been able to supply himself.

Examples of Mythology.—Myths of the origin of the world and man are naturally most widely diffused. Man has everywhere asked himself whence things came and how, and his myths are his earliest extant form of answer to this question. So confused and inconsistent are the mythical answers that it is very difficult to classify them according to any system. If we try beginning with myths of creative gods, we find that the world is sometimes represented as pre-existent to the divine race. If we try beginning with myths of the origin of the world, we frequently find that it owes its origin to the activity of pre-existent supernatural beings. According to all modern views of creation, the creative mind is prior to the universe which it created. There is no such consistency of opinion in myths, whether of civilized or savage races. Perhaps the plan least open to objection is to begin with myths of the gods. But when we speak of gods, we must not give to the word a modern significance. As used here, gods merely mean non-natural and powerful beings, sometimes "magnified non-natural men," sometimes beasts, birds, or insects, sometimes the larger forces and phenomena of the universe conceived of as endowed with human personality and passions. When Plutarch examined the Osirian myth (*De Isid.*, xxv.) he saw that the "gods" in the tale were really "demons," "stronger than men, but having the divine part not wholly unalloyed,"—"magnified non-natural men," in short. And such are the gods of mythology. In examining the myths of the gods we propose to begin with the conceptions of the most backward tribes, and to advance to the divine legends of the ancient civilized races. It will appear that, while the non-civilized gods are often theriomorphic, made in accordance with the ideas of non-civilized men, the civilized gods retain many characteristics of the savage gods, and these characteristics are the "irrational element" in the divine myths.

Myths of Gods. Savage ideas.—The Boó-noo-rong, an Australian coast-tribe, regard as an early creative god a being named Bun-jel or Pund-jel. He is the chief of a supernatural set of beings, earlier than men, with human relationships. He has a wife whose face (in accordance with a widely-diffused scruple of savage etiquette) he has never seen, any more than Urvasi in the Vedic myth was allowed to see Pururavas without his garments, "for such is the custom" (says the *Veda*) "of women." The name Bun-jel means "eagle-hawk," and the eagle-hawk is a "totem," or worshipful ancestral animal, among certain Australian tribes. Conceived as a supernatural bird-god, Pund-jel answers to the birds as they describe themselves in Aristophanes (*Aves*, 703)—

ὧδε μέν ἐσμεν
πολὺ πρεσβύτατοι πάντων μακάρων.

He belongs to the age of birds, "altogether wiser and more skilful in all things than men," "by far the most ancient of all gods." In an anthropomorphic myth of the Kurnai, Pund-jel figures as "an old man who lives at the sources of the Yarra river" and is rich in cattle. The term Bun-jel is also used as a kind of title of honour bestowed on the older men of the Kurnai and Briakolung, some of whom have magical powers. In the northern parts of Victoria the aborigines believe in Pund-jel in his bird-form as a creative Eagle. Pund-jel takes the part, not only of a creator, but of an instructor—a "culture-hero," to use a fashionable compound term. He instructed man in the arts of life, taught the males how to spear kangaroos, and the women how to dig roots. Pund-jel disappeared from the world he had made when a rival power, the Jay, opened certain great bags of wind he possessed, and blew Pund-jel into the heavens. The Australians draw no very hard-and-fast line between their "birraarks," or sorcerers, and their gods. The Kurnai give the name of Brewin to a powerful spirit, but the name was also conferred on a birraark who disappeared for many days, holding converse with the invisible. The native bear is a beast they adore, and they have given his name to a famous sorcerer. The West Wind is the name of a human sorcerer who happens to be able to make the west wind blow with violence. There is thus a come and go of titles, powers, and attributes between sorcerers, totems, and vague powerful spirits, and in this medley of beliefs a god may have the form of a bird, a man the attributes of a god, so that every sort of irrational transformation is not only not unnatural but is inevitable in such a system. The basis of that system,

of course, is the belief in the equal personality and common kindred of all things. Pund-jel, and his rivals the Crow and the Jay, appear to belong to the supernatural prehuman race of Nurrumbunguttias, or "old spirits," answering to the divine races of Titans and gods in Greece, and to the Californian and Ovaherero "old ones in heaven."[1]

Before leaving the Australian divine myths it should be remarked that the widely-spread dualistic myth is found among the Australians. "Why do things go wrong?" men ask, and answer, in Australia as in Persia, by the myth of the mischievous power who thwarted the maker of things. Among the Australians the Crow was always at war with the creative Eagle. The Eagle, by the way (like the elder brothers of Zeus), was once swallowed by a powerful god who afterwards became the moon, and was disgorged alive. The Eagle's adventures as a creator will more properly be considered among cosmogonic myths. His share in the dispersion of mankind, and in causing the deluge, cannot but be regarded with some suspicion, though they bear but distant resemblances to the Biblical narratives.

The chief being among the supernatural characters of Bushman mythology is the insect called the Mantis.[2] Cagn or Ikaggen, the Mantis, is sometimes regarded with religious respect as a benevolent god. But his adventures are the merest nightmares of puerile fancy. He has a wife, an adopted daughter, whose real father is the "swallower" in Bushman swallowing-myths, and the daughter has a son, who is the Ichneumon. The Mantis made an eland out of the shoe of his son-in-law. The moon was also created by the Mantis out of his shoe, and it is red, because the shoe was covered with the red dust of Bushman-land. The Mantis is defeated in an encounter with a cat which happened to be singing a song about a lynx. The Mantis (like Poseidon, Hades, Metis, and other Greek gods) was once swallowed, but disgorged alive. The swallower was the monster Ilkhwai-hemm. Like Heracles when he leaped into the belly of the monster which was about to swallow Hesione, the Mantis once jumped down the throat of a hostile elephant, and so destroyed him. The heavenly bodies are gods among the Bushmen, but their nature and adventures must be discussed among other myths of sun, moon, and stars. As a creator, Cagn is sometimes said to have "given orders, and caused all things to appear and be made." He struck snakes with his staff and turned them into men, as Zeus did with the ants in Ægina. But the Bushmen's mythical theory of the origin of things must, as far as possible, be kept apart from the fables of the Mantis, the Ichneumon, and other divine beings. Though animals, these gods have human passions and character, and possess the usual magical powers attributed to sorcerers.

Concerning the mythology of the Hottentots and Namas, we have a great deal of information in a book named *Tsuni-Goam, the Supreme Being of the Khoi-Khoi* (1881), by Dr T. Hahn. This author has collected the old notices of Hottentot myths, and has added material from his own researches. The chief god of the Hottentots is a being named Tsuni-Goam, who is universally regarded by his worshippers as a deceased sorcerer. According to one old believer, "Tsui-Goab" (an alternative reading of the god's name) "was a great powerful chief of the Khoi-Khoi—in fact, he was the first Khoi-Khoib from whom all the Khoi-Khoi tribes took their name." He is always represented as at war (in the usual crude dualism of savages) with "another chief" named Gaunab. The prayers addressed to Tsui-Goab are simple and natural in character, the "private ejaculations" of men in moments of need or distress. As usual, religion is more advanced than mythology. It appears that, by some accounts, Tsui-Goab lives in the red sky and Gaunab in the dark sky. The neighbouring race of Namas have another old chief for god, a being called Heitsi Eibib. His graves are shown in many places, like those of Osiris, which, says Plutarch, abounded in Egypt. He is propitiated by passers-by at his sepulchres. He has intimate relations in peace and war with a variety of animals whose habits are sometimes explained (like those of the serpent in Genesis) as the result of the curse of Heitsi Eibib. Heitsi Eibib was born in a mysterious way from a cow, as Indra in the *Black Yajur-Veda* entered into and was born from the womb of a being who also bore a cow. The *Rig-Veda* (iv. 18, 1) remarks, "His mother, a cow, bore Indra, an unlicked calf,"—probably a metaphorical way of speaking. Heitsi Eibib, like countless other gods and heroes, is also said to have been the son of a virgin who tasted a particular plant, and so became pregnant, as in the German and Gallophrygian märchen of the almond tree, given by Grimm and Pausanias. Incest is one of the feats of Heitsi Eibib. Tsui-Goab, in the opinion of his worshippers, as we have seen, is a deified dead sorcerer, whose name means Wounded Knee, the sorcerer having been injured in the knee by an enemy. Dr Hahn tries to prove (by philology's "artful aid") that the name really means "red dawn," and is a Hottentot way of speaking of the infinite. The philological arguments advanced are extremely weak, and by no means convincing. If we grant, however, for the sake of argument, that the early Hottentots worshipped the infinite under the figure of the dawn, and that, by forgetting their own meaning, they came to believe that the words which really meant "red dawn" meant "wounded knee," we must still admit that the devout have assigned to their deity all the attributes of an ancestral sorcerer. In short, their "Red Dawn," if red dawn he be, is a person, and a savage person, adored exactly as the actual fathers and grandfathers of the Hottentots are adored. We must explain his legend, then, on these principles, and not as an allegory of the dawn as the dawn appears to civilized people. About Gaunab (the Ahriman to Tsui-Goab's Ormuzd) Dr Hahn gives two distinct opinions. "Gaunab was at first a ghost, a mischief-maker and evil-doer" (*op. cit.*, p. 85). But Gaunab he declares to be "the night-sky" (p. 126). Whether we regard Gaunab, Heitsi Eibib, and Tsui-Goab as originally mythological representations of natural phenomena, or as deified dead men, it is plain that they are now venerated as non-natural human beings, possessing the customary attributes of sorcerers. Thus of Tsui-Goab it is said, "He could do wonderful things which no other man could do, because he was very wise. He could tell what would happen in future times. He died several times, and several times he rose again" (statement of old Kχarab in Hahn, p. 61).

The mythology of the Zulus as reported by Callaway (*Unkulunkulu*, 1868-70) is very thin and uninteresting. The Zulus are great worshippers of ancestors (who appear to men in the form of snakes), and they regard a being called Unkúlunkúlu as their first ancestor, and sometimes as the creator, or at least as the maker of men. It does not appear they identify Unkúlunkúlu, as a rule, with "the lord of heaven," who, like Indra, causes the thunder. The word answering to our lord is also applied "even to beasts, as the lion and the boa." The Zulus, like many distant races, sometimes attribute thunder to the "thunder-

[1] The chief sources used here are Fison and Ridley's *Kamilaroi and Kurnai*, with Brough Smyth's *Aborigines of Victoria*. Dawson's work, and Gason on the Dieyries, with Sir George Grey's *Travels*, may also be consulted.

[2] Accounts of the Mantis and of his performances will be found in the *Cape Monthly Magazine*, July 1874, and in Dr Bleek's *Brief Account of Bushman Folk-Lore*.

bird," which, as in North America, is occasionally seen and even killed by men. "It is said to have a red bill, red legs, and a short red tail like fire. The bird is boiled for the sake of the fat, which is used by the heaven-doctors to puff on their bodies, and to anoint their lightning-rods." The Zulus are so absorbed in propitiating the shades of their dead (who, though in serpentine bodies, have human dispositions) that they appear to take little pleasure in mythological narratives. At the same time, the Zulus have many "nursery tales," the plots and incidents of which often bear the closest resemblance to the heroic myths of Greece, and to the märchen of European peoples.[1] These indications will give a general idea of African divine myths. On the west coast the "ananzi" or spider takes the place of the mantis insect among the Bushmen. For some of his exploits Dasent's *Tales from the Norse* (2d ed., Appendix) may be consulted.

Turning from the natives of Australia, and from African races of various degrees of culture, to the Papuan inhabitants of Melanesia, we find that mythological ideas are scarcely on a higher level. There is an excellent account of the myths of the Banks Islanders and Solomon Islanders in *Journ. Anthropol. Inst.* (February 1881), by the Rev. R. H. Codrington. The article contains a critical description of the difficulty with which missionaries obtain information about the prior creeds. The people of the Banks Islands are chiefly ancestor-worshippers, but they also believe in, and occasionally pray to, a being named I Qat, one of the prehuman race endowed with supernatural powers who here, as elsewhere, do duty as gods. Here is an example of a prayer to Qat,—the devotee is supposed to be in danger with his canoe. "Qate! Marawa! look down on me, smooth the sea for us two that I may go safely on the sea. Beat down for me the crests of the tide-rip; let the tide-rip settle down away from me, beat it down level that it may sink and roll away, and I may come to a quiet landing-place." Compare the prayer of Odysseus to the river, whose mouth he had reached after three days' swimming on the tempestuous sea: "'Hear me, O king, whosoever thou art, unto thee I am come as to one to whom prayer is made . . . nay, pity me, O king, for I avow myself thy suppliant.' So spake he, and the god stayed his stream, and withheld his waves, and made the water smooth before him" (*Odyssey*, v. 450). The prayer of the Melanesian is on rather a higher religious level than that of the Homeric hero. The myths of Qat's adventures, however, are very crude, though not so wild as some of the Scandinavian myths about Odin and Loki, while they are less immoral than the adventures of Indra and Zeus. Qat was born in the isle of Vanua Levu; his mother was either a stone at the time of his birth, or was turned into a stone afterwards, like Niobe. The mother of Apollo, according to Ælian, had the misfortune to be changed into a wolf. Qat had eleven brothers, not much more reputable than the Osbaldistones in *Rob Roy*. The youngest brother was "Tangaro Loloqong, the Fool." His pastime was to make wrong all that Qat made right, and he is sometimes the Ahriman to Qat's Ormuzd. The creative achievements of Qat must be treated of in the next section. Here it may be mentioned that, like the hero in the Breton märchen, Qat "brought the dawn" by introducing birds whose notes proclaimed the coming of morning. Before Qat's time there had been no night, but he purchased a sufficient allowance of darkness from I Qong, that is, night considered as a person in accordance with the law of savage thought already explained. Night is a person in Greek mythology, and in the fourteenth book of the *Iliad* we read that Zeus abstained from punishing Sleep "because he feared to offend swift Night." Qat produced dawn, for the first time, by cutting the darkness with a knife of red obsidian. Afterwards "the fowls and birds showed the morning." On one occasion an evil power (Vui) slew all Qat's brothers, and hid them in a food-chest. As in the common "swallowing-myths" which we have met among Bushmen and Australians, and will find among the Greeks, Qat restored his brethren to life. Qat is always accompanied by a powerful supernatural spider named Marawa. He first made Marawa's acquaintance when he was cutting down a tree for a canoe. Every night (as in the common European story about bridge-building and church-building) the work was all undone by Marawa, whom Qat found means to conciliate. In all his future adventures the spider was as serviceable as the cat in *Puss-in-Boots* or the other grateful animals in European legend. Qat's great enemy, Qasavara, was dashed against the hard sky, and was turned into stone, like the foes of Perseus. The stone is still shown in Vanua Levu, like the stone which was Zeus in Laconia. Qat, like so many other "culture-heroes," disappeared mysteriously, and white men arriving in the island have been mistaken for Qat. His departure is sometimes connected with the myth of the deluge. In the New Hebrides, Tagar takes the rôle of Qat, and Suqe of the bad principle, Loki, Ahriman, Tangaro Loloqong, the Australian Crow, and so forth. These are the best-known divine myths of the Melanesians, and it is obvious that such gods as exist there are magnified non-natural men or animals with the powers of sorcerers. So far there seems to be no good reason for connecting the gods (if gods they can be called) with the elemental phenomena.

It is "a far cry" from Vanua Levu to Vancouver's Island, and, ethnologically, the Ahts of the latter region are extremely remote from the Papuans with their mixture of Malay and Polynesian blood. The Ahts, however, differ but little in their mythological beliefs from the races of the Banks Islands or of the New Hebrides. In Sproat's *Scenes from Savage Life* (1868) there is a good account of Aht opinions by a settler who had won the confidence of the natives between 1860 and 1868. "There is no end to the stories which an old Indian will relate," says Mr Sproat, when "one quite possesses his confidence." "The first Indian who ever lived" is a divine being, something of a creator, something of a first father, like Unkûlunkûlu among the Zulus. His name is Quawteaht. He married a pre-existent bird, the thunder-bird Tootah (we have met him among the Zulus), and by the bird he became the father of Indians. Wispohahp is the Aht Noah, who, with his wife, his two brothers, and their wives, escaped from the deluge in a canoe. Quawteaht is inferior as a deity to the Sun and Moon. He is the Yama of an Aht paradise, or home of the dead, where "everything is beautiful and abundant." From all that is told of Quawteaht he seems to be an ideal and powerful Aht, imaginatively placed at the beginning of things, and quite capable of intermarriage with a bird. His creative exploits must be considered later. Quawteaht is the Aht Prometheus Purphoros, or fire-stealer.

Passing down the American continent from the north-west, we find Yehl the chief hero-god and mythical personage among the Thlinkeets. Like many other heroes or gods, Yehl had a miraculous birth. His mother, a Thlinkeet woman, whose sons had all been slain, met a friendly dolphin, which advised her to swallow a pebble and a little sea-water. The birth of Yehl was the result. In his youth he shot a supernatural crane, and can always fly about in its feathers, like Odin and Loki in Scandi-

[1] These are collected by Callaway, *Zulu Nursery Tales*, 1868. Similar Kaffre stories, also closely resembling the popular fictions of European races, have been published by Theal. Many other examples are published in the *South African Folk-Lore Journal*, 1879, 1880.

navian myth. He is usually, however, regarded as a raven, and holds the same relation to men and the world as the eagle-hawk Pund-jel does in Australia. His great opponent (for the eternal dualism comes in) is Khanukh, who is a wolf, and the ancestor or totem of the wolf-race of men as Yehl is of the raven. The opposition between the Crow and Eagle-hawk in Australia will be remembered. Both animals or men or gods take part in creation. Yehl is the Prometheus Purphoros of the Thlinkeets, but myths of the fire-stealer would form matter for a separate section. Yehl also stole water, in his bird-shape, exactly as Odin stole "Suttung's mead" when in the shape of an eagle.[1] Yehl's powers of metamorphosis and of flying into the air are the common accomplishments of sorcerers, and he is a rather crude form of first father, "culture-hero," and creator.[2]

Among the Cahroc Indians we find the great hero and divine benefactor in the shape of, not a raven, nor an eagle-hawk, nor a mantis insect, nor a spider, but a coyote. Among both Cahrocs and Navajos the Coyote is the Prometheus Purphoros, or, as the Aryans of India call him, Matarisvan the fire-stealer. Among the Papagos, on the eastern side of the Gulf of California, the Coyote or Prairie Wolf is the creative hero and chief supernatural being. In Oregon the Coyote is also the "demiurge," but most of the myths about him refer to his creative exploits, and will be more appropriately treated in the next section.

Moving up the Pacific coast to British Columbia, we find the Musk-rat taking the part played by Vishnu, when in his avatar as a boar he fished up the earth from the waters. Among the Tinnehs a miraculous dog, who, like an enchanted fairy prince, could assume the form of a handsome young man, is the chief divine being of the myths. He too is chiefly a creative or demiurgic being, answering to Purusha in the *Rig-Veda*. So far the peculiar mark of the wilder American tribe legends is the bestial character of the divine beings, which is also illustrated in Australia and Africa, while the bestial clothing, feathers or fur, drops but slowly off Indra, Zeus and the Egyptian Ammon, and the Scandinavian Odin. All these are more or less anthropomorphic, but retain, as will be seen, numerous relics of a theriomorphic condition.

Passing from the lower savage myths, of which space does not permit us to offer a larger selection, we turn to races in the upper strata of barbarism. Among these the Maoris of New Zealand, and the Polynesian people generally, are remarkable for a mythology largely intermixed with early attempts at more philosophical speculation. The Maoris and Mangaians, and other peoples, have had speculators among them not very far removed from the mental condition of the earliest Greek philosophers, Empedocles, Anaximander, and the rest. In fact the process from the view of nature which we call personalism to the crudest theories of the physicists was apparently begun in New Zealand before the arrival of Europeans. In Maori mythology it is more than usually difficult to keep apart the origin of the world and the origin and nature of the gods. Long traditional hymns give an account of the "becoming out of nothing" which resulted in the evolution of the gods and the world. In the beginning (as in the Greek myths of Uranus and Gæa), Heaven (Rangi, conceived of as a person) was indissolubly united to his wife Earth (Papa), and between them they begat gods which necessarily dwelt in darkness. These gods were some in vegetable, some in animal form; some traditions place among these gods Tiki the demiurge, who (like Prometheus) made men out of clay. The offspring of Rangi and Papa (kept in the dark as they were) held a council to determine how they should treat their parents, "Shall we slay them, or shall we separate them?" In the Hesiodic fable, Cronus separates the heavenly pair by mutilating his oppressive father Uranus. Among the Maoris the god Tutenganahau cut the sinews which united Earth and Heaven, and Tane Mahuta wrenched them apart, and kept them eternally asunder. The new dynasty now had earth to themselves, but Tawhiramatea, the wind, abode aloft with his father. Some of the gods were in the forms of lizards and fishes; some went to the land, some to the water. As among the gods and Asuras of the *Vedas*, there were many wars in the divine race, and as the incantations of the Indian *Brahmanas* are derived from those old experiences of the Vedic gods, so are the incantations of the Maoris. The gods of New Zealand, the greater gods at least, may be called "departmental;" each person who is an elementary force is also the god of that force. As Te Heu, a powerful chief, said, there is division of labour among men, and so there is among gods. "One made this, another that; Tane made trees, Ru mountains, Tanga-roa fish, and so forth."[3] The "departmental" arrangement prevails among the polytheism of civilized peoples, and is familiar to all from the Greek examples. Leaving the high gods whose functions are so large, while their forms (as of lizard, fish, and tree) are often so mean, we come to Maui, the great divine hero of the supernatural race in Polynesia. Maui in some respects answers to the chief of the Adityas in Vedic mythology; in others he answers to Qat, Quawteaht, and other savage divine personages. Like the son of the Vedic Aditi,[4] Maui is a rejected and abortive child of his mother, but afterwards attains to the highest reputation. As Qat brought the hitherto unknown night, so Maui settled the sun and moon in their proper courses. He induced the sun to move orderly by giving him a violent beating. A similar feat was performed by the Sun-trapper, a famous Red Indian chief. These tales belong properly to the department of solar myths. Maui himself is thought by Mr E. B. Tylor to be a myth of the sun, but the sun could hardly give the sun a drubbing. Maui slew monsters, invented barbs for fish-hooks, frequently adopted the form of various birds, acted as Prometheus Purphoros the fire-stealer, drew a whole island up from the bottom of the deep; he was a great sorcerer and magician. Had Maui succeeded in his attempt to pass through the body of Night (considered as a woman) men would have been immortal. But a little bird which sings at sunset wakened Night, she snapped up Maui, and men die. This has been called a myth of sunset, but the sun does what Maui failed to do, he passes through the body of night unharmed. The adventure is one of the myths of the origin of death, which are almost universally diffused. Maui, though regarded as a god, is not often addressed in prayer.[5]

The whole system, as far as it can be called a system, of Maori mythology is obviously based on the savage conceptions of the world which have already been explained. The Polynesian system differs mainly in detail; we have the separation of heaven and earth, the animal-shaped gods, the fire-stealing, the exploits of Maui, and scores of minor myths in Gill's *Myths and Songs of the South Pacific*, in the researches of Ellis, of Williams, in Turner's *Polynesia*, and in many other accessible works.

The Maoris and other Polynesian peoples are perhaps the best examples of a race which has risen far above the savagery of Bushmen and Australians, but has not yet

[5] The best authorities for the New Zealand myths are the old traditional priestly hymns, collected and translated in the works of Sir George Grey, in Taylor's *New Zealand*, in Shortland's *Traditions of New Zealand* (1857), and in Bastian's *Heilige Sage der Polynesier*.

arrived at the stage in which great centralized monarchies appear. The Mexican and Peruvian civilizations were far ahead of Maori culture, in so far as they possessed the elements of a much more settled and highly-organized society. Their religion had its fine lucid intervals, but their mythology and ritual were little better than savage ideas, elaborately worked up by the imagination of a cruel and superstitious priesthood. In cruelty the Aztecs surpassed perhaps all peoples of the Old World, except certain Semitic stocks, and their gods, of course, surpassed almost all other gods in bloodthirstiness. But in grotesque and savage points of faith the ancient Egyptians, the Greeks, and the Vedic Indians ran even the Aztecs pretty close.

Bernal Diaz, the old "conquistador," has described the hideous aspect of the idols which Cortes destroyed, "idols in the shape of hideous dragons as big as calves," idols half in the form of men, half of dogs, and serpents which were worshipped as divine. The old contemporary missionary Sahagun has left one of the earliest detailed accounts of the natures and myths of these gods, but, though Sahagun took great pains in collecting facts, his speculations must be accepted with caution. He was convinced (like Caxton in his *Destruction of Troy*, and like St Augustine) that the heathen gods were only dead men worshipped. Ancestor-worship is a great force in early religion, and the qualities of dead chiefs and sorcerers are freely attributed to gods, but it does not follow that each god was once a real man, as Sahagun supposes. Euemerism cannot be judiciously carried so far as this. Of Huitzilopochtli, the famed god, Sahagun says that he was a necromancer, loved "shape-shifting," like Odin, metamorphosed himself into animal forms, was miraculously conceived, and, among animals, is confused with the humming-bird, whose feathers adorned his statues.[1] This humming-bird god should be compared with the Roman Picus (Servius, 189). That the humming-bird (Nuitziton), which was the god's old shape, should become merely his attendant (like the owl of Pallas, the mouse of Apollo, the goose of Priapus, the cuckoo of Hera), when the god received anthropomorphic form, is an example of a process common in all mythologies. Plutarch observes that the Greeks, though accustomed to the conceptions of the animal attendants of their own gods, were amazed when they found animals worshipped as gods by the Egyptians. Müller[2] mentions the view that the humming-bird, as the most beautiful flying thing, is a proper symbol of the heaven, and so of the heaven-god, Huitzilopochtli. This vein of symbolism is so easy to work that it must be regarded with distrust. Perhaps it is safer to attribute theriomorphic shapes of gods, not to symbolism (Zeus was a cuckoo), but to survivals from that quality of early thought which draws no line between man and god and beast and bird and fish. If spiders may be great gods, why not the more attractive humming-birds? Like many other gods, Huitzilopochtli slew his foes at his birth, and hence received names analogous to Δειμός and Φόβος. Mr Tylor (*Primitive Culture*, ii. 307) calls Huitzilopochtli an "inextricable compound parthenogenetic god." His sacrament, when paste idols of him were eaten by the communicants, was at the winter solstice, whence it may, perhaps, be inferred that Huitzilopochtli was not only a war-god but a nature-god,—in both respects anthropomorphic, and in both bearing traces of the time when he was but a humming-bird, as Yehl was a raven (Müller, *op. cit.*, p. 595). As a humming-bird, Huitzilopochtli led the Aztecs to a new home, as a wolf led the Hirpini, and as a woodpecker led the Sabines. Quetzalcoatl, the Toltec deity, is as much a sparrow (or similar small bird) as Huitzilopochtli is a humming-bird. Acosta says he retained the sparrow's head in his statue. For the composite character of Quetzalcoatl as a "culture-hero" (a more polished version of Qat), as a "nature-god," and as a theriomorphic god see Müller (*op. cit.*, pp. 583-584). Müller frankly recognizes that not only are animals symbols of deity and its attributes, not only are they companions and messengers of deity (as in the period of anthropomorphic religion), but they have been divine beings in and for themselves during the earlier stages of thought. The Mexican "departmental" gods answer to those of other polytheisms; there is an Aztec Ceres, an Aztec Lucina, an Aztec Vulcan, an Aztec Flora, an Aztec Venus. The creative myths and sun myths are crude and very early in character.

Egyptian Myths.—On a much larger and more magnificent scale, and on a much more permanent basis, the society of ancient Egypt somewhat resembled that of ancient Mexico. The divine myths of the two nations had points in common, but there are few topics more obscure than Egyptian mythology. Writers are apt to speak of Egyptian religion as if it were a single phenomenon of which all the aspects could be observed at a given time. In point of fact Egyptian religion (conservative though it was) lasted through perhaps five thousand years, was subject to innumerable influences, historical, ethnological, philosophical, and was variously represented by various schools of priests. We cannot take the Platonic speculations of Iamblichus about the nature and manifestations of Egyptian godhead as evidence for the belief of the peoples who first worshipped the Egyptian gods an innumerable series of ages before Iamblichus and Plutarch. Nor can the esoteric and pantheistic theories of priests (according to which the various beast-gods were symbolic manifestations of the divine essence) be received as an historical account of the origin of the local animal-worships. It has already been shown that the lowest and least intellectual races indulge in local animal-worship, each stock having its parent bird, beast, fish, or even plant, or inanimate object. It has also been shown that these backward peoples recognize a non-natural race of men or animals, or both, as the first fathers, heroes, and, in a sense, gods. Such ideas are consonant with, and may be traced to the confused and nebulous condition of, savage thought. Precisely the same ideas are found at various periods among the ancient Egyptians. If we are to regard the Egyptian myths about the gods in animal shape, and about the non-natural superhuman heroes, and their wars and loves, as esoteric allegories devised by civilized priests, perhaps we should also explain Pund-jel, Qat, Quawteaht, the Mantis god, the Spider creator, the Coyote and Raven gods as priestly inventions, put forth in a civilized age, and retained by Australians, Bushmen, Hottentots, Ahts, Thlinkeets, Papuans, who preserve no other vestiges of high civilization. Or we may take the opposite view, and regard the story of Osiris and his war with Seth (who shut him up in a box and mutilated him) as a dualistic myth, originally on the level of the battle between Gaunab and Tsui-Goab, or between Tagar and Suqe. We may regard the local beast- and plant-gods of Egypt as survivals of totems and totem-gods like those of Australia, India, America, Africa, Siberia, and other countries. In this article the latter view is adopted. The beast-gods and dualistic and creative myths of savages are looked on as the natural product of the savage reason and fancy. The same beast-gods and myths in civilized Egypt are looked on as survivals from the rude and early condition of thought to which such conceptions are natural.

In the most ancient Egyptian records the gods are not pictorially represented, and we have not obtained from these records any descriptions of adoration and sacrifice. There is a prayer to the Sky on the coffin of the king of Dynasty IV., known as Mycerinus to the Greeks. The

king describes himself as the child of Sky and Earth. He also somewhat obscurely identifies himself with Osiris.

We thus find Osiris very near the beginning of what is known about Egyptian religion. This being is rather a culture-hero, a member of a non-natural race of men like Qat or Manabozho, than a god. His myth, to be afterwards narrated, is found pictorially represented in a tomb and in the late temple of Philæ, is frequently alluded to in the litanies of the dead about 1400 B.C., is indicated with reverent awe by Herodotus, and after the Christian era is described at full length by Plutarch. Whether the same myth was current in the far more distant days of Mycerinus, it is, of course, impossible to say with dogmatic certainty. The religious history of Egypt, from perhaps Dynasty X. to Dynasty XX., is interrupted by an invasion of Semitic conquerors and Semitic ideas. Prior to that invasion the gods, when mentioned in monuments, are always represented by animals, and these animals are the object of strictly local worship. The name of each god is spelled in hieroglyphs beside the beast or bird. The jackal stands for Anup, the hawk for Har, the frog for Hekt, the baboon for Tahuti, and Ptah, Asiri, Hesi, Nebhat, Hat-hor, Neit, Khnum, and Amun-hor are all written out phonetically, but never represented in pictures. Different cities had their different beast-gods. Pasht, the cat, was the god of Bubastis; Apis, the bull, of Memphis; Hapi, the wolf, of Sioot; Ba, the goat, of Mendes. The evidence of Herodotus, Plutarch, and the other writers shows that the Egyptians of each district refused to eat the flesh of the animal they held sacred. So far the identity of custom with savage totemism is absolute. Of all the explanations, then, of Egyptian animal-worship, that which regards the practice as a survival of totemism and of savagery seems the most satisfactory. So far Egyptian religion only represented her gods in theriomorphic shape. Beasts also appeared in the royal genealogies, as if the early Egyptians had filled up the measure of totemism by regarding themselves as actually descended from animals.

With one or two exceptions, "the first (semi-anthropomorphic) figures of gods known in the civilized parts of Egypt are on the granite obelisk of Bezig in the Fayyúm, erected by Usertesen I. of Dynasty XII., and here we find the forms all full-blown at once. The first group of deities belongs to a period and a district in which Semitic influences had undoubtedly begun to work."[1] From this period the mixed and monstrous figures, semi-theriomorphic, semi-anthropomorphic, hawk-headed and ram-headed and jackal-headed gods become common. This may be attributed to Semitic influence, or we may suppose that the process of anthropomorphizing theriomorphic gods was naturally developing itself; for Mexico has shown us and Greece can show us abundant examples of these mixed figures, in which the anthropomorphic god retains traces of his theriomorphic past. The heretical worship of the solar disk interrupted the course of Egyptian religion under some reforming kings, but the great and glorious Ramesside Dynasty (XIX.) restored "Orus and Isis and the dog Anubis" with the rest of the semi-theriomorphic deities. These survived even their defeat by the splendid human gods of Rome, and only "fled from the folding star of Bethlehem."

Though Egypt was rich in gods, her literature is not fertile in myths. The religious compositions which have survived are, as a rule, hymns and litanies, the funereal service, the "Book of the Dead." In these works the myths are taken for granted, are alluded to in the course of addresses to the divine beings, but, naturally, are not told in full. As in the case of the *Vedas*, hymns are poor sources for the study of mythology, just as the hymns of the church would throw little light on the incidents of the gospel story or of the Old Testament. The "sacred legends" which the priests or temple servants freely communicated to Herodotus are lost through the pious reserve of the traveller. Herodotus constantly alludes to the most famous Egyptian myth, that of Osiris, and he recognizes the analogies between the Osirian myth and mysteries and those of Dionysus. But we have to turn to the very late authority of Plutarch (*De Iside et Osiride*) for an account, confessedly incomplete and expurgated, of what mythology had to tell about the great Egyptian "culture-hero," "dæmon," and god. Osiris, Horus, Typhon (Seth), Isis, and Nephthys were the children of Seb (whom the Greeks identified with Cronus); the myths of their birth were peculiarly savage and obscene. Osiris introduced civilization into Egypt, and then wandered over the world, making men acquainted with agriculture and the arts, as Pund-jel in his humbler way did in Australia. On his return Typhon laid a plot for him. He had a beautiful carved chest made which exactly fitted Osiris, and at an entertainment offered to give it to any one who could lie down in it. As soon as Osiris tried, Typhon had the box nailed up, and threw it into the Tanaite branch of the Nile. Isis wandered, mourning, in search of the body, as Demeter sought Persephone, and perhaps in Plutarch's late version some incidents may be borrowed from the Eleusinian legend. At length she found the chest, which in her absence was again discovered by Typhon. He mangled the body of Osiris (as so many gods of all races were mangled) and tossed the fragments about. Wherever Isis found a portion of Osiris she buried it; hence Egypt was as rich in graves of Osiris as Namaqualand in graves of Heitsi Eibib. The phallus alone she did not find, but she consecrated a model thereof; hence (says the myth) came the phallus-worship of Egypt. Afterwards Osiris returned from the shades, and (in the form of a wolf) urged his son Horus to revenge him on Typhon. The gods fought in animal shape (Birch, in Wilkinson, iii. 144). Plutarch purposely omits as "too blasphemous" the legend of the mangling of Horus. Though the graves of these non-natural beings are shown, the priests (*De Is. et Os.*, xxi.) also show the stars into which they were metamorphosed, as the Eskimo and Australians and Aryans of India and Greeks have recognized in the constellations their ancient heroes. Plutarch remarked the fact that the Greek myths of Cronus, of Dionysus, of Apollo and the Python, and of Demeter, "all the things that are shrouded in mystic ceremonies and are presented in rites," "do not fall short in absurdity of the legends about Osiris and Typhon." Plutarch naturally presumed that the myths which seem absurd shrouded some great moral or physical mystery. But we apply no such explanation to similar savage legends, and our theory is that the Osirian myth is only one of these retained to the time of Plutarch by the religious conservatism of a race which, to the time of Plutarch, preserved in full vigour most of the practices of totemism. As a slight confirmation of the possibility of this theory we may mention that Greek mysteries retained two of the features of savage mysteries. The first was the rite of daubing the initiated with clay.[2] This custom prevails in African mysteries, in Guiana, among Australians, Papuans, and Andaman Islanders. The other custom is the use of the *turndun*, as the Australians call a little fish-shaped piece of wood tied to a string, and waved so as to produce a loud booming and whirring noise and keep away the profane, especially women. It is employed in New Mexico, South Africa, New Zealand, and Australia. This instrument, the κῶνος,

[1] This extract, with much of what goes before, is from a paper read to the Royal Literary Society by Mr Flinders Petrie.

[2] Demosthenes, *De Corona*, p. 313, καὶ καθαίρων τοὺς τελουμένους καὶ ἀπομάττων τῷ πηλῷ καὶ τοῖς πιτύροις.

was also used in Greek mysteries.[1] Neither the use of the *κῶνος* nor of the clay can very well be regarded as a civilized practice retained by savages. The hypothesis that the rites and the stories are savage inventions surviving into civilized religion seems better to meet the difficulty. That the Osirian myth (much as it was elaborated and allegorized) originated in the same sort of fancy as the Tacullie story of the dismembered beaver out of whose body things were made is a conclusion not devoid of plausibility. Typhon's later career, "committing dreadful crimes out of envy and spite, and throwing all things into confusion," was parallel to the proceedings of most of the divine beings who put everything wrong, in opposition to the being who makes everything right. This is perhaps an early "dualistic" myth.

Among other mythic Egyptian figures we have Ra, who once destroyed men in his wrath with circumstances suggestive of the deluge; Khnum, a demiurge, is represented at Philæ as making man out of clay on a potter's wheel. Here the wheel is added to the Maori conception of the making of man. Khnum is said to have reconstructed the limbs of the dismembered Osiris. Ptah is the Egyptian Hephæstus; he is represented as a dwarf; men are said to have come out of his eye, gods out of his mouth,—a story like that of Purusha in the *Rig-Veda*. As creator of man, Ptah is a frog. Bubastis became a cat to avoid the wrath of Typhon. Ra, the sun, fought the big serpent Apap, as Indra fought Vrittra. Seb is a goose, called "the great cackler;" he laid the creative egg.[2]

Divine Myths of the Aryans of India. Indra.—The gods of the *Vedas* and *Brahmanas* (the ancient hymns and canonized ritual-books of Aryan India) are, on the whole, of the usual polytheistic type. More than many other gods they retain in their titles and attributes the character of elemental phenomena personified. That personification is, as a rule, anthropomorphic, but traces of theriomorphic personification are still very apparent. The ideas which may be gathered about the gods from the hymns are (as is usual in heathen religions) without consistency. There is no strict orthodoxy. As each bard of each bardic family celebrates his favourite god he is apt to make him for the moment the pre-eminent deity of all. This way of thinking about the gods leads naturally in the direction of a pantheistic monotheism in which each divine being may be regarded as a manifestation of the one divine essence. No doubt this point of view was attained in centuries extremely remote by sages of the civilized Vedic world. It is easy, however, to detect certain peculiar characteristics of each god. As among races much less advanced in civilization than the Vedic Indians, each of the greater powers has his own separate department, however much his worshippers may be inclined to regard him as an absolute premier with undisputed latitude of personal government. Thus Indra is mainly concerned with thunder and other atmospheric phenomena; but Vayu is the wind, the Maruts are wind-gods, Agni is fire or the god of fire, and so connected with lightning. Powerful as Indra is in the celestial world, Mitra and Varuna preside over night and day. Ushas is the dawn, and Twashtri is the mechanic among the gods, corresponding to the Egyptian Ptah and the Greek Hephæstus. Though lofty moral qualities and deep concern about the conduct of men are attributed to the gods in the Vedic hymns, yet the hymns contain traces (and these are amplified in the ritual books) of a divine *chronique scandaleuse*. In this *chronique* the gods, like other gods, are adventurous warriors, adulterers, incestuous, homicidal, given to animal transformations, cowardly, and in fact charged with all human vices, and credited with magical powers.[3] It would be difficult to speak too highly of the ethical nobility of many Vedic hymns. The "hunger and thirst after righteousness" of the sacred poet recalls the noblest aspirations and regrets of the Hebrew psalmist. But this aspect of the Vedic deities is essentially matter for the science of religion rather than of mythology, which is concerned with the stories told about the gods. Religion is always forgetting, or explaining away, or apologizing for these stories. Now the Vedic deities, so imposing when regarded as vast natural forces (as such forces seem to us), so benignant when appealed to as forgivers of sins, have also their mythological aspect. In this aspect they are natural phenomena still, but phenomena as originally conceived of by the personifying imagination of the savage, and credited, like the gods of the Maori or the Australian, with all manner of freaks, adventures, and disguises. The *Veda*, it is true, does not usually dilate much on the worst of these adventures. The *Veda* contains devotional hymns; we can no more expect much narrative here than in the psalms of David. Again, the religious sentiment of the *Veda* is half-consciously hostile to the stories. As M. Barth says, "Le sentiment religieux a écarté la plupart des mythes, mais il ne les a écartés tous." The *Brahmanas*, on the other hand, later compilations, canonized books for the direction of ritual and sacrifice, are rich in senseless and irrational myths. Sometimes these myths are probably later than the *Veda*, mere explanations of ritual incidents devised by the priests. Sometimes a myth probably older than the *Vedas*, and maintained in popular tradition, is reported in the *Brahmanas*. The gods in the *Veda* are by no means always regarded as equal in supremacy. There were great and small, young and old gods (*R.-V.*, i. 27, 13). Elsewhere this is flatly contradicted: "None of you, oh gods, is small or young, ye are all great" (*R.-V.*, viii. 30, 1). As to the immortality and the origin of the gods, there is no orthodox opinion in the *Veda*. Many of the myths of the origin of the divine beings are on a level with the Maori theory that Heaven and Earth begat them in the ordinary way. Again, the gods were represented as the children of Aditi. This may be taken either in a refined sense, as if Aditi were the "infinite" region from which the solar deities rise,[4] or we may hold with the *Taittirya-Brahmana*[5] that Aditi was a female who, being desirous of offspring, cooked a *brahmandana* offering for the Sadhyas. Various other fathers and mothers of the gods are mentioned. Some gods, particularly Indra, are said to have won divine rank by "austere fervour" and asceticism, which is one of the processes that makes gods out of mortals even now in India.[6] The gods are not always even credited with inherent immortality. Like men, they were subject to death, which they overcame in various ways. Like most gods, they had struggles for pre-eminence with Titanic opponents, the Asuras, who partly answer to the Greek Titans and the Hawaiian foes of the divine race, or to the Scandinavian giants and the enemies who beset the savage creative beings. Early man, living in a state of endless warfare, naturally believes that

[1] *Κῶνος ξυλάριον οὗ ἐξῆπται τὸ σπαρτίον, καὶ ἐν ταῖς τελεταῖς ἐδονεῖτο ἵνα ῥοιζῇ.* Quoted by Lobeck, *Aglaophamus*, i. 700, from Bastius ad Gregor., 241, and from other sources; cf. Arnobius, v. c. 19, where the word *turbines* is the Latin term.

[2] Wilkinson, iii. 62, see note by Dr. Birch. The authorities on Egyptian religion are given under Egypt (vol. vii. pp. 714-719). Unfortunately Egyptologists have rarely a wide knowledge of the myths of the lower races, while anthropologists are seldom or never Egyptologists.

[3] For examples of the lofty morality sometimes attributed to the gods, see Max Müller, *Hibbert Lectures*, p. 234; *Rig-Veda*, ii. 23; iv. 12, 4; viii. 93 *sq.*; Muir, *Sanskrit Texts*, v. 218.

[4] Müller, *Hibbert Lectures*, p. 229.

[5] Muir, *S. T.*, v. 55; i. 27.

[6] See Sir A. Lyall, *Asiatic Studies*. For Vedic examples, see *R.-V.*, x. 167, 1; x. 159, 4; Muir, *S. T.*, v. 15.

his gods also have their battles. The chief foes of Indra are Vrittra and Ahi, serpents which swallow up the waters, precisely as frogs do in Australian and Californian and Andaman myths. It has already been shown that such creatures, thunder-birds, snakes, dragons, and what not, people the sky in the imagination of Zulus, Red Men, Chinese, Peruvians, and all the races who believe that beasts hunt the sun and moon and cause eclipses.[1] Though hostile to Asuras, Indra was once entangled in an intrigue with a woman of that race, according to the *Atharva-Veda* (Muir, *S. T.*, v. 82). The gods were less numerous than the Asuras, but by a magical stratagem turned some bricks into gods (like a creation of new peers to carry a vote),—so says the *Black Yajur-Veda*.[2]

Turning to separate gods, Indra first claims attention, for stories of Heaven and Earth are better studied under the heading of myths of the origin of things. Indra has this zoomorphic feature in common with Heitsi Eibib, the Namaqua god,[3] that his mother, or one of his mothers, was a cow (*R.-V.*, iv. 18, 1). This statement may be a mere way of speaking in the *Veda*, but it is a rather Hottentot way.[4] Indra is also referred to as a ram in the *Veda*, and in one myth this ram could fly, like the Greek ram of the fleece of gold. He was certainly so far connected with sheep that he and sheep and the Kshatriya caste sprang from the breast and arms of Prajapati, a kind of creative being. Indra was a great drinker of soma juice: a drinking-song by Indra, much bemused with soma, is in *R.-V.*, x. 119. On one occasion Indra got at the soma by assuming the shape of a quail. In the *Taitt. Sanh.* (ii. 5; i. 1) Indra is said to "have been guilty of that most hideous crime, the killing of a Brâhmana."[5] Once, though uninvited, Indra drank some soma that had been prepared for another being. The soma disagreed with Indra: part of it which was not drunk up became Vrittra the serpent, Indra's enemy. Indra cut him in two, and made the moon out of half of his body. This serpent was a universal devourer of everything and everybody, like Kwai Hemm, the all-devourer in Bushman mythology. If this invention is a late priestly one, the person who introduced it into the *Satapatha-Brahmana* must have reverted to the intellectual condition of Bushmen. In the fight with Vrittra, Indra lost his energy, which fell to the earth and produced plants and shrubs. In the same way plants, among the Iroquois, were made of pieces knocked off Chokanipok in his fight with Manabozho. Vines, in particular, are the entrails of Chokanipok. In Egypt, wine was the blood of the enemies of the gods. The Aryan versions of this sensible legend will be found in *Satapatha-Brahmana*.[6] The civilized mind soon wearies of this stuff, and perhaps enough has been said to prove that, in the traditions of Vedic devotees, Indra was not a god without an irrational element in his myth. Our argument is, that all these legends about Indra, of which only a sample is given, have no necessary connexion with the worship of a pure nature-god as a nature-god would now be constructed by men. The legends are survivals of a time in which natural phenomena were regarded, not as we regard them, but as persons, and savage persons, and became the centres of legends in the savage manner. Space does not permit us to recount the equally puerile and barbarous legends of Vishnu, Agni, the loves of Vivasvat in the form of a horse, the adventures of Soma, nor the Vedic amours (paralleled in several savage mythologies) of Pururavas and Urvasi.[7]

Divine Myths of Greece.—If any ancient people was thoroughly civilized the Greeks were that people. Yet in the mythology and religion of Greece we find abundant survivals of savage manners and of savage myths. As to the religion, it is enough to point to the traces of human sacrifice and to the worship of rude fetich stones. The human sacrifices at Salamis in Cyprus and at Alos in Achaia Phthiotis may be said to have continued almost to the conversion of the empire (Grote, i. 125, ed. 1869). Pausanias seems to have found human sacrifices to Zeus still lingering in Arcadia in the 2d century of our era. "On this altar on the Lycæan hill they sacrifice to Zeus in a manner that may not be spoken, and little liking had I to pry far into that sacrifice. But let it be as it is, and as it hath been from the beginning." Now "from the beginning" the sacrifice, according to Arcadian tradition, had been a human sacrifice. In other places there were manifest commutations of human sacrifice, as at the altar of Artemis the Implacable at Patræ, where Pausanias saw the wild beasts being driven into the flames.[8] Many other examples of human sacrifice are mentioned in Greek legend. Pausanias gives full and interesting details of the worship of rude stones, the oldest worship, he says, among the Greeks. Almost every temple had its fetich stone on a level with the pumice stone, which is the Poseidon of the Mangaians.[9] The Argives had a large stone called Zeus Cappotas. The oldest idol of the Thespians was a rude stone. Another has been found beneath the pedestal of Apollo in Delos. In Achæan Pharæ were thirty squared stones, each named by the name of a god. Among monstrous images of the gods which Pausanias, who saw them, regarded as the oldest idols, were the three-headed Artemis, each head being that of an animal, the Demeter with the horse's head, the Artemis with the fish's tail, the Zeus with three eyes, the ithyphallic Hermes, represented after the fashion of the Priapic figures in paintings on the walls of caves among the Bushmen. We also hear of the bull and the bull-footed Dionysus. Phallic and other obscene emblems were carried abroad in processions in Attica both by women and men. The Greek custom of daubing people all over with clay in the mysteries results as we saw in the mysteries of Negroes, Australians, and American races, while the Australian *turndun* was exhibited among the toys at the mysteries of Dionysus. The survivals of rites, objects of worship, and sacrifices like these prove that religious conservatism in Greece retained much of savage practice, and the Greek mythology is not less full of ideas familiar to the lowest races. The authorities for Greek mythology are numerous and various in character. The oldest sources as literary documents are the Homeric and Hesiodic poems. In the *Iliad* and *Odyssey* the gods and goddesses are beautiful, powerful, and immortal anthropomorphic beings. The name of Zeus (Skr. *Dyaus*) clearly indicates his connexion with the sky. But in Homer he has long ceased to be merely the sky conceived of as a person; he is the

[2] The chief authority for the constant strife between gods and Asuras is the *Satapatha-Brahmana*, of which one volume is translated in *Sacred Books of the East* (vol. xii.).

[3] Hahn, *Tsuni-Goam, the Supreme Being of the Hottentots*, p. 68.

[4] See Muir, *S. T.*, v. 16, 17, for Indra's peculiar achievements with a cow.

[5] *Sacred Books of the East*, xii. 1, 48.

[6] *Ib.*, xii. 176, 177.

[7] On the whole subject, Dr Muir's *Ancient Sanskrit Texts*, with translations, Ludwig's translation of the *Rig-Veda* already referred to, and the translation of the *Satapatha-Brahmana* already referred to, and the translation of the *Aitareya-Brahmana* by Haug, are the sources most open to English readers. Mr Max Muller's translation of the *Rig-Veda* unfortunately only deals with the hymns to the Maruts. The Indian epics and the *Puranas* belong to a much later date, and are full of deities either unknown to or undeveloped in the *Rig-Veda* and the *Brahmanas*. It is much to be regretted that the *Atharva-Veda*, which contains the magical formulæ and incantations of the Vedic Indians is still untranslated, though, by the very nature of its theme, it must contain matter of extreme antiquity and interest.

[8] Pausanias, iii. 16; vii. 18. Human sacrifice to Dionysus, Paus. vii. 21; Plutarch, *De Is. et Os.* 35; Porphyry, *De Abst.* ii. 55.

chief personage in a society of immortals, organized on the type of contemporary human society. "There is a great deal of human nature" in his wife Hera (Skr. *Svar*, Heaven).[1] It is to be remembered that philologists differ widely as to the origin and meaning of the names of almost all the Greek gods. Thus the light which the science of language throws on Greek myths is extremely uncertain. Hera is explained as "the feminine side of heaven" by some authorities. The quarrels of Hera with Zeus (which are a humorous anthropomorphic study in Homer) are represented as a way of speaking about winter and rough weather. The other chief Homeric deities are Apollo and Artemis, children of Zeus by Leto, a mortal mother raised to divinity. Apollo is clearly connected in some way with light, as his name Φοῖβος seems to indicate, and with purity.[2] Homer knows the legend that a giant sought to lay violent hands on Leto (*Od.*, xi. 580). Smintheus, one of Apollo's titles in Homer, is connected with the field-mouse (σμίνθος), one of his many sacred animals. His names, Λύκιος, Λυκηγενής, were connected by antiquity with the wolf, by most modern writers with the light. According to some legends Leto had been a were-wolf.[3] The whole subject of the relations of Greek gods to animals is best set forth in the words of Plutarch (*De Is. et Os.*, lxxi.), where he says that the Egyptians worship actual beasts, "whereas the Greeks both speak and believe correctly, saying that the dove is the sacred animal of Aphrodite, the raven of Apollo, the dog of Artemis," and so forth. Each Greek god had a small menagerie of sacred animals, and it may be conjectured that these animals were originally the totems of various stocks, subsumed into the worship of the anthropomorphic god. Apollo, in any case, is the young and beautiful archer-god of Homer; Artemis, his sister, is the goddess of archery, who takes her pastime in the chase. She holds no considerable place in the *Iliad*; in the *Odyssey*, Nausicaa is compared to her, as to the pure and lovely lady of maidenhood. Her name is commonly connected with ἀρτεμής,—pure, unpolluted. Her close relations (un-Homeric) with the bear and bear-worship have suggested a derivation from ἄρκτος—Ἄρκτεμις. In Homer her "gentle shafts" deal sudden and painless death; she is a beautiful Azrael. A much more important daughter of Zeus in Homer is Athene, the "grey-eyed" or (as some take γλαυκῶπις, rather improbably) the "owl-headed" goddess. Her birth from the head of Zeus is not explicitly alluded to in Homer.[4] In Homer, Athene is a warlike maiden, the patron-goddess of wisdom and manly resolution. In the twenty-second book of the *Odyssey* she assumes the form of a swallow, and she can put on the shape of any man. She bears the ægis, the awful shield of Zeus. Another Homeric child of Zeus, or, according to Hesiod (*Th.*, 927), of Hera alone, is Hephæstus, the lame craftsman and artificer. In the *Iliad*[5] will be found some of the crudest Homeric myths. Zeus or Hera throws Hephæstus or Ate out of heaven, as in the Iroquois myth of the tossing from heaven of Ataentsic. There is, as usual, no agreement as to the etymology of the name of Hephæstus. Preller inclines to a connexion with ἅφθαι, to kindle fire, but Mr Max Müller differs from this theory. About the close relations of Hephæstus with fire there can be no doubt. He is a rough, kind, good-humoured being in the *Iliad*. In the *Odyssey* he is naturally annoyed by the adultery of his wife, Aphrodite, with Ares. Ares is a god with whom Homer has no sympathy. He is a son of Hera, and detested by Zeus (*Iliad*, v. 890). He is cowardly in war, and on one occasion was shut up for years in a huge brazen pot. This adventure was even more ignominious than that of Poseidon and Apollo when they were compelled to serve Laomedon for hire. The payment he refused, and threatened to "cut off their ears with the sword" (*Iliad*, xxi. 455). Poseidon is to the sea what Zeus is to the air, and Hades to the underworld in Homer.[6] His own view of his social position may be stated in his own words (*Iliad*, xv. 183, 211).

"Three brethren are we, and sons of Cronus, sons whom Rhea bare, even Zeus and myself, and Hades is the third, the ruler of the people in the underworld. And in three lots were all things divided, and each drew a lot of his own,[7] and to me fell the hoary sea, and Hades drew the mirky darkness, and Zeus the wide heaven in clear air and clouds, but the earth and high Olympus are yet common to all."

Zeus, however, is, as Poseidon admits, the elder-born, and therefore the revered head of the family. Thus Homer adopts the system of primogeniture, while Hesiod is all for the opposite and probably earlier custom of "*jüngsten-recht*," and makes supreme Zeus the youngest of the sons of Cronus. Among the other gods Dionysus is but slightly alluded to in Homer as the son of Zeus and Semele, as the object of persecution, and as connected with the myth of Ariadne. The name of Hermes is derived from various sources, as from ὁρμᾶν and ὁρμή, or, by Mr Max Müller, the name is connected with Sarameya (Sky). If he had originally an elemental character, it is now difficult to distinguish, though interpreters connect him with the wind. He is the messenger of the gods, the bringer of good luck, and the conductor of men's souls down the dark ways of death. In addition to the great Homeric gods, the poet knows a whole "Olympian consistory" of deities, nymphs, nereids, sea-gods and goddesses, river-gods, Iris the rainbow goddess, Sleep, Demeter who lay with a mortal, Aphrodite the goddess of love, wife of Hephæstus and leman of Ares, and so forth. As to the origin of the gods, Homer is not very explicit. He is acquainted with the existence of an older dynasty now deposed, the dynasty of Cronus and the Titans. In the *Iliad* (viii. 478) Zeus says to Hera, "For thine anger reck I not, not even though thou go to the nethermost bounds of earth and sea, where sit Iapetus and Cronus . . . and deep Tartarus is round about them." "The gods below that are with Cronus" are mentioned (*Il.*, xiv. 274; xv. 225). Rumours of old divine wars echo in the *Iliad*, as (i. 400) where it is said that when the other immortals revolted against and bound Zeus, Thetis brought to his aid Ægæon of the hundred arms. The streams of Oceanus (*Il.*, xiv. 246) are spoken of as the source of all the gods, and in the same book (290) "Oceanus and mother Tethys" are regarded as the parents of the immortals. Zeus is usually called Cronion and Cronides, which Homer certainly understood to mean "son of Cronus," yet it is expressly stated that Zeus "imprisoned Cronus beneath the earth and the unvintaged sea." The whole subject is only alluded to incidentally. On the whole it may be said that the Homeric deities are powerful anthropomorphic beings, departmental rulers, united by the ordinary social and family ties of the Homeric

[1] Cf. Preller, *Griechische Mythologie*, i. 128, note 1, for this and other philological conjectures.

[2] The derivation of Ἀπόλλων remains obscure. The derivation of Leto from λαθεῖν, and the conclusion that her name means "the concealer," that is, the night, whence the sun is born, is disputed by Curtius (Preller, i. 190, 191, note 4), but appears to be accepted by Mr Max Muller (*Selected Essays*, i. 386), Latmos being derived from the same root as Leto, Latona, the night.

[3] Aristotle, *H. An.*, 6; Ælian, *N. A.*, 4, 4.

[4] Her name, as usual, is variously interpreted by various etymologists. Some connect Ἀθήνη with αἰθ, as in αἰθής. Mr Max Muller connects it with *ahana* (Skr., dawn), but it is not universally admitted that *ahana* does mean "dawn," nor that the derivation is correct.

[5] xiv. 257; xviii. 395; xix. 91, 132.

[6] The root of his name is sought in such words as πότος and ποταμός.

[7] We learn from the *Odyssey* (xiv. 209) that this was the custom of sons on the death of their father.

age, capable of pain and pleasure, living on heavenly food, but refreshed by the sacrifices of men (*Od.*, v. 100, 102), able to assume all forms at will, and to intermarry and propagate the species with mortal men and women. Their past has been stormy, and their ruler has attained power after defeating and mediatizing a more ancient dynasty of his own kindred.

From Hesiod we receive a much more elaborate, probably a more ancient, certainly a more barbarous, story of the gods and their origin. In the beginning the gods (here used in a wide sense to denote an early non-natural race) were begotten by Earth and Heaven, conceived of as beings with human parts and passions (Hesiod, *Theog.*, 45). This idea recurs in Maori, Vedic, and Chinese mythology. Heaven and Earth, united in an endless embrace, produced children which never saw the light. In New Zealand, Chinese, Vedic, Indian, and Greek myths the pair had to be sundered.[1] Hesiod enumerates the children whom Earth bore "when couched in love with Heaven." They are Ocean, Cœus, Crius, Hyperion, Iapetus, Theia, Rhea, Themis, Mnemosyne, Phœbe, Tethys, and the youngest, Cronus, "and he hated his glorious father." Others of this early race were the Cyclopes, Bronte, Sterope, and Arge, and three children of enormous strength, Cottus, Briareus (Ægæon), and Gyes, each with one hundred hands and fifty heads. Uranus detested his offspring, and hid them in crannies of Earth. Earth excited Cronus to attack the father, whom he castrated with a sickle. From the blood of Uranus (this feature is common in Red Indian and Egyptian myths) were born furies, giants, ash-nymphs, and Aphrodite. A number of monsters, as Echidna, Geryon, and the hound of hell, were born of the loves of various elemental powers. The chief stock of the divine species was continued by the marriage of Rhea (probably another form of the Earth) with Cronus. Their children were Hestia, Demeter, Hera, Hades, and Poseidon. All these Cronus swallowed; and this "swallow-myth" occurs in Australia, among the Bushmen, in Guiana, in Brittany (where Gargantua did the swallow trick), and elsewhere. At last Rhea bore Zeus, and gave Cronus a stone in swaddling bands, which he disposed of in the usual way. Zeus grew up, administered an emetic to Cronus (some say Metis did this), and had the satisfaction of seeing all his brothers and sisters disgorged alive. The stone came forth first, and Pausanias saw it at Delphi (Paus., x. 24). Then followed the wars between Zeus and the gods he had rescued from the maw of Cronus against the gods of the elder branch, the children of Uranus and Gæa,—Heaven and Earth. The victory remained with the younger branch, the immortal Olympians of Homer. The system of Hesiod is a medley of later physical speculation and of poetic allegory, with matter which we, at least, regard as savage survivals, like the mutilation of Heaven and the swallow-myth.[2]

In Homer and in Hesiod myths enter the region of literature, and become, as it were, national. But it is probable that the local myths of various cities and temples, of the "sacred chapters" which were told by the priests to travellers and in the mysteries to the initiated, were older in form than the epic and national myths. Of these "sacred chapters" we have fragments and hints in Herodotus, Pausanias, in the mythographers, like Apollodorus, in the tragic poets, and in the ancient *scholia* or notes on the classics. From these sources come almost all the more inhuman, bestial, and discreditable myths of the gods. In these we more distinctly perceive the savage element. The gods assume animal forms: Cronus becomes a horse, Rhea a mare; Zeus begets separate families of men in the shape of a bull, an ant, a serpent, a swan. His mistress from whom the Arcadians claim descent becomes a she-bear. It is usual with mythologists to say that Zeus is the "all-father," and that his amours are only a poetic way of stating that he is the parent of men. But why does he assume so many animal shapes? Why did various royal houses claim descent from the ant, the swan, the she-bear, the serpent, the horse, and so forth? We have already seen that this is the ordinary pedigree of savage stocks in Asia, Africa, Australia, and America, while animals appear among Irish tribes, and in Egyptian and ancient English genealogies.[3] It is a plausible hypothesis that stocks which once claimed descent from animals, *sans phrase*, afterwards regarded the animals as avatars of Zeus. In the same way "the Minas, a non-Aryan tribe of Rajputana, used to worship the pig; when the Brahmans got a turn at them, the pig became an avatar of Vishnu" (Lyall, *Asiatic Studies*). The tales of divine cannibalism to which Pindar refers with awe, the mutilation of Dionysus Zagreus, the unspeakable abominations of Dionysus, the loves of Hera in the shape of a cuckoo, the divine powers of metamorphosing men and women into beasts and stars,—these tales come to us as echoes of the period of savage thought. Further evidence on this point will be given below in a classification of the principal mythic legends. The general conclusion is that many of the Greek deities were originally elemental, the elements being personified in accordance with the laws of savage imaginations. But we cannot explain each detail in the legends as a myth of this or that natural phenomenon or process as understood by ourselves. Various stages of late and early fancy have contributed to the legends. Zeus is the sky, but not our sky; he had originally a personal character, and that a savage or barbarous character. He probably attracted into his legend stories that did not originally belong to him. He became anthropomorphic, and his myth was handled by local priests, by family bards, by national poets, by early philosophers. His legend is a complex embroidery on a very ancient tissue. The other divine myths are equally complex.

Scandinavian Divine Myths.—The Scandinavian myths of the gods are numerous and interesting, but the evidence on which they have reached us demands criticism for which we lack space. That there are in the *Eddas* and *Sagas* early ideas and later ideas tinged by Christian legend seems indubitable, but philological and historical learning has by no means settled the questions of relative purity and antiquity in the myths. The Eddic songs, according to Mr Powell, one of the editors of the *Corpus Poeticum Septentrionale* (the best work on the subject), "cannot date earlier" in their present form "than the 9th century," and may be vaguely placed between 800-1100 A.D. The collector of the *Edda* probably had the old poems recited to him in the 13th century, and where there was a break

[1] See Tylor, *Prim. Cult.*, i. 326.

[2] Bleek, *Bushman Folk-Lore*, pp. 6-8. Mr Max Muller suggests another theory (*Selected Essays*, i. 460): "Κρόνος did not exist till long after Ζεύς in Greece." The name Κρονίων, or Κρονίδης, looks like a patronymic. Mr Muller, however, thinks it originally meant only "connected with time, existing through all time." Very much later the name was mistaken for a genuine patronymic, and "Zeus the ancient of days" became "Zeus the son of Cronus." Having thus got a Cronus, the Greeks—and "the misunderstanding could have happened in Greece only"—needed a myth of Cronus. They therefore invented or adapted the "swallow-myth" so familiar to Bushmen and Australians. This singular reversion to savagery itself needs some explanation. But the hypothesis that Cronus is a late derivation from Κρονίδης and Κρονίων is by no means universally accepted. Others derive Κρόνος from κραίνω, and connect it with κρόνια, a kind of harvest home festival. Schwartz (*Prähistorisch-anthropologische Studien*) readily proves Cronus to be the storm, swallowing the clouds. Perhaps we may say of Schwartz's view, as he says of Preller's—"das ist Gedankenspiel, aber nimmermehr Mythologie."

[3] Elton, *Origins of English History*, 298-301.

in the memory of the reciters the *lacuna* was filled up in prose. "As one goes through the poems, one is ever and anon face to face with a myth of the most childish and barbaric type," which "carries one back to pre-Aryan days." Side by side with these old stories come fragments of a different stratum of thought, Christian ideas, the belief in a supreme God, the notion of Doomsday. The Scandinavian cosmogonic myth (with its parallels among races savage and civilized) is given elsewhere. The most important god is Odin, the son of Bestla and Bor, the husband of Frigg, the father of Balder and many other sons, the head of the Æsir stock of gods. Odin's name is connected with that of Wuotan, and referred to the Old High German verb *watan wuot = meare, cum impetu ferri* (Grimm, *Teut. Myth.*, Engl. transl., i. 131). Odin would thus (if we admit the etymology) be the swift goer, the "ganger," and it seems superfluous to make him (with Grimm) "the all-powerful, all-permeating being," a very abstract and scarcely an early conception. Odin's brethren (in *Gylfi's Mocking*) are Vile and Ve, who with him slew Ymir the giant, and made all things out of the fragments of his body. They also made man out of two stocks. In the *Hava-Mal* Odin claims for himself most of the attributes of the medicine-man. In *Loka Senna*, Loki, the evil god, says that "Odin dealt in magic in Samsey." The goddess Frigg remarks, "Ye should never talk of your old doings before men, of what ye two Æsir went through in old times." But many relics of these "old times," many traces of the medicine-man and the "skin-shifter," survive in the myth of Odin. When he stole Suttung's mead (which answers somewhat to nectar and the Indian soma), he flew away in the shape of an eagle.[1] The hawk is sacred to Odin; one of his names is "the Raven-god." He was usually represented as one-eyed, having left an eye in pawn that he might purchase a draught from Mimir's well. This one eye is often explained as the sun. Odin's wife was Frigg; their sons were Thor (the thunder-god) and Balder, whose myth is well known in English poetry. The gods were divided into two, not always friendly, stocks, the Æsir and Vanir. Their relations are, on the whole, much more amicable than those of the Asuras and Devas in Indian mythology. Not necessarily immortal, the gods restored their vigour by eating the apples of Iduna. Asa Loki was a being of mixed race, half god, half giant, and wholly mischievous and evil. His legend includes animal metamorphoses of the most obscene character. In the shape of a mare he became the mother of the eight-legged horse of Odin. He borrowed the hawk-dress of Freya, when he recovered the apples of Iduna. Another Eddic god, Hœne, is described in phrases from lost poems as "the long-legged one," "lord of the ooze," and his name is connected with that of the crane. The constant enemies of the gods, the giants, could also assume animal forms. Thus in Thiodolf's *Haust-long* (composed after the settlement of Iceland) we read about a shield on which events from mythology were painted; among these was the flight of "giant Thiazzi in an ancient eagle's feathers." The god Herindal and Loki once fought a battle in the shapes of seals. On the whole, the Scandinavian gods are a society on an early human model, of beings indifferently human, animal, and divine,—some of them derived from elemental forces personified, holding sway over the elements, and skilled in sorcery. Probably after the viking days came in the conceptions of the last war of gods, and the end of all, and the theory of Odin All-father as a kind of emperor in the heavenly world. The famous tree that lives through all the world is regarded as "foreign, Christian, and confined to few poems." There is, almost undoubtedly, a touch of the Christian dawn on the figure and myth of the pure and beloved and ill-fated god Balder, and his descent into hell. The whole subject is beset with critical difficulties, and we have chiefly noted features which can hardly be regarded as late, and which correspond with widely-distributed mythical ideas.[2]

It is now necessary to cast a hasty glance over the chief divisions of myths. These correspond to the chief problems which the world presents to the curiosity of untutored men. They ask themselves (and the answers are given in myths) the following questions:—What is the Origin of the World? The Origin of Man? Whence came the Arts of Life? Whence the Stars? Whence the Sun and Moon? What is the Origin of Death? How was Fire procured by Man? The question of the origin of the marks and characteristics of various animals and plants has also produced a class of myths in which the marks are said to survive from some memorable adventure, or the plants and animals to be metamorphosed human beings. Examples of all these myths are found among savages and in the legends of the ancient civilizations. A few such examples may now be given.

Myths of the Origin of the World.—We have found it difficult to keep myths of the gods apart from myths of the origin of the world and of man, because gods are frequently regarded as creative powers. The origin of things is a problem which has everywhere exercised thought, and been rudely solved in myths. These vary in quality with the civilization of the races in which they are current, but the same ideas which we proceed to state pervade all cosmogonical myths, savage and civilized. All these legends waver between the theory of creation, or rather of manufacture, and the theory of evolution. The earth, as a rule, is supposed to have grown out of some original matter, perhaps an animal, perhaps an egg which floated on the waters, perhaps a fragment of soil fished up out of the floods by a beast or a god. But this conception does not exclude the idea that many of the things in the world, minerals, plants, people, and what not, are fragments of the frame of an animal or non-natural magnified man, or are excretions from the body of a god. We proceed to state briefly the various forms of these ideas. The most backward races usually assume the prior existence of the earth.

The aborigines of the northern parts of Victoria (Australia) believe that the earth was made by Pund-jel, the bird-creator, who sliced the valleys with a knife. Another Australian theory is that the men of a previous race, the Nooralie (very old ones), made the earth.

The problem of the origin of the world seems scarcely to have troubled the Bushmen. They know about "men who brought the sun," but their doctrines are revealed in mysteries, and Qing, the informant of Mr Orpen (*Cape Monthly Magazine*, July 1874), "did not dance that dance," that is, had not been initiated into all the secret doctrines of his tribe. According to Qing, creation was the work of Cagn (the mantis insect), "he gave orders and caused all things to appear." Elsewhere in the myth Cagn made or manufactured things by his skill.

As a rule the most backward races, while rich in myths of the origin of men, animals, plants, stones, and stars, do not say much about the making of the world. Among people a little more advanced, the earth is presumed to have grown out of the waters. In the Iroquois myth (Lafitan, *Mœurs des Sauvages*, 1724), a heavenly woman was tossed out of heaven, and fell on a turtle, which developed into the world. Another North-American myth assumes a single

---

[1] Indra was a hawk when, "being well-winged, he carried to men the food tasted by the gods" (*R.-V.*, iv. 26, 4). Yehl, the Thlinkeet god-hero, was a raven or a crane when he stole the water (Bancroft, iii. 100-102). The prevalence of animals, or of god-animals, in myths of the stealing of water, soma, and fire, is very remarkable. Among the Andaman Islanders, a kingfisher steals fire for men from the god Puluga (*Anthrop. Journal*, November 1882).

[2] Dasent's *Prose or Younger Edda* (Stockholm, 1842), the *Corpus Septentrionale* already referred to, Mr Keary's *Mythology of the Eddas*, Pigott's *Manual of Scandinavian Mythology* (1838), and Laing's *Early Kings of Norway* may be consulted by English students. For Germanic myths at large, Grimm's celebrated *German Mythology*, translated by Mr Stallybrass, may be studied, and Mr Keary's *Outlines of Primitive Belief*. German divine myths are necessarily scarce, owing to the early conversion of Germany before a pre-Christian literature, like the *Eddas*, was preserved. Obscure classical notices, and survivals in folk-lore, mediæval and modern, are the chief sources of information. The divine names, however, prove that the German was in form not alien to the Scandinavian mythology. The märchen in Grimm's and other collections belong rather to the heroic myths than to those concerned with gods.

island in the midst of the waters, and this island grew into the world. The Navajos and the Digger Indians take earth for granted as a starting-point in their myths. The Winnebagos, not untouched by Christian doctrine, do not go farther back. The Great Manitou awoke and found himself alone. He took a piece of his body and a piece of earth and made a man. Here the existence of earth is assumed (Bancroft, iv. 228). Even in Guatemala, though the younger sons of a divine race succeed in making the earth where the elder son (as usual) failed, they all had a supply of clay as first material. The Pimas, a Central-American tribe, say the earth was made by a powerful being, and at first appeared "like a spider's web." This reminds one of the Anansi or spider creator of West Africa. The more metaphysical Tacullies of British Columbia say that in the beginning nought existed but water and a musk-rat. The musk-rat sought his food at the bottom of the water, and his mouth was frequently filled with mud. This he kept spitting out, and so formed an island, which developed into the world. Among the Tinnehs, the frame of a dog (which could assume the form of a handsome young man) became the first material of most things. The dog, like Osiris, Dionysus, Purusha, and other gods, was torn to pieces by giants: the fragments became many of the things in the world (Bancroft, i. 106). Even here the existence of earth for the dog to live in is assumed.

Coming to races more advanced in civilization, we find the New Zealanders in possession of ancient hymns in which the origin of things is traced back to nothing, to darkness, and to a metaphysical process from nothing to something, from being to becoming. The hymns may be read in Sir George Grey's *Polynesian Mythology*, and in Taylor's *New Zealand*. It has been suggested that these hymns bear traces of Buddhist and Indian influence; in any case, they are rather metaphysical than mystical. Myth comes in when the Maoris represent Rangi and Papa, Heaven and Earth, as two vast beings, male and female, united in a secular embrace, and finally severed by their children, among whom Tane Mahuta takes the part of Cronus in the Greek myth. The gods were partly elemental, partly animal in character; the lists of their titles show that every human crime was freely attributed to them. In the South Sea Islands, generally, the fable of the union and separation of Heaven and Earth is current; other forms will be found in Gill's *Myths and Songs from the South Pacific*.

The Greek cosmogonic myths have already been alluded to in the passage on divine myths in Greece.

The cosmogonic myths of the Aryans of India are peculiarly interesting, as we find in the *Vedas* and *Brahmanas* and *Puranas* almost every fiction familiar to savages side by side with the most abstract metaphysical speculations. We have the theory that earth grew, as in the Iroquois story of the turtle, from a being named Uttanapad (Muir, v. 335). We find that Brahmanaspati "blew the gods forth from his mouth," and one of the gods, Tvashtri, the mechanic among the deities, is credited with having fashioned the earth and the heaven (Muir, v. 354). The "Purusha Sukta," the 90th hymn of the tenth book of the *Rig-Veda*, gives us the Indian version of the theory that all things were made out of the mangled limbs of Purusha, a magnified non-natural man, who was sacrificed by the gods. As this hymn gives an account of the origin of the castes (which elsewhere are scarcely recognized in the *Rig-Veda*), it is sometimes regarded as a late addition. But we can scarcely think the main conception late, as it is so widely scattered that it meets us in most mythologies, including those of Chaldæa and Egypt, and various North-American tribes. Not satisfied with this myth, the Aryans of India accounted for the origin of species in the following barbaric style. A being named Purusha was alone in the world. He differentiated himself into two beings, husband and wife. The wife, regarding union with her producer as incest, fled from his embraces as Nemesis did from those of Zeus, and Rhea from Cronus, assuming various animal disguises. The husband pursued in the form of the male of each animal, and from these unions sprang the various species of beasts (*Satapatha-Brahmana*, xiv. 4, 2; Muir, i. 25). The myth of the cosmic egg from which all things were produced is also current in the *Brahmanas*. In the *Puranas* we find the legend of many successive creations and destructions of the world a myth of world-wide distribution.

As a rule, destruction by a deluge (see DELUGE) is the most favourite myth, but destructions by fire and wind and by the wrath of a god are common in Australian, Peruvian, and Egyptian tradition. The idea that a boar, or a god in the shape of a boar, fished up a bit of earth which subsequently became the world out of the waters, is very well known to the Aryans of India, and recalls the feats of American musk-rats and coyotes already described.[1] The tortoise from which all things sprang, in a myth of the *Satapatha-Brahmana*, reminds us of the Iroquois turtle. The Greek and Mangaian myth of the marriage of Heaven and Earth and its dissolution is found in the *Aitareya-Brahmana* (Haug's trans., ii. 308; *Rig-Veda*, i. lxii.).

So much for the Indian cosmogonic myths, which are a collection of ideas familiar to savages, blended with sacerdotal theories and ritual mummeries. The philosophical theory of the origin of things, a hymn of remarkable stateliness, is in *Rig-Veda*, x. 129. The Scandinavian cosmogonic myth starts from the abyss, Ginnungagap, a chaos of ice, from which, as it thawed, was produced the giant Ymir. Ymir is the Scandinavian Purusha. A man and woman sprang from his armpit, like Athene from the head of Zeus. A cow licked the hoar-frost, whence rose Bur, whose children, Odin, Vile, and Ve, slew the giant Ymir. "Of his flesh they formed the earth, of his blood seas and waters, of his bones mountains, of his teeth rocks and stones, of his hair all manner of plants." This is the story in the *Prose Edda*, derived from older songs, such as the *Grimnersmal*. However the distribution of this singular myth may be explained, its origin can scarcely be sought in the imagination of races higher in culture than the Tinnehs and Tacullies, among whom dogs and beavers are the theriomorphic form of Purusha or Ymir.

Myths of the Origin of Man.—These partake of the conceptions of evolution and of creation. Man was made out of clay by a supernatural being. *Australia*: man was made by Pund-jel. *New Zealand*: man was made by Tiki; "he took red clay, and kneaded it with his own blood." *Mangaia*: the woman of the abyss made a child from a piece of flesh plucked out of her own side. *Melanesia*: "man was made of clay, red from the marshy side of Vanua Levu;" woman was made by Qat of willow twigs. *Greece*: men were πλάσματα πηλοῦ, figures baked in clay by Prometheus.[2] *India*: men were made after many efforts, in which the experimental beings did not harmonize with their environment, by Prajapati. In another class of myths, man was evolved out of the lower animals,—lizards in Australia; coyotes, beavers, apes, and other beasts in America. The Greek myths of the descent of the Arcadians, Myrmidons, children of the swan, the cow, and so forth, may be compared. Yet again, men came out of trees or plants or rocks: as from the Australian wattle gum, the Zulu bed of reeds, the great tree of the Ovahereros, the rock of the tribes in Central Africa, the cave of Bushman and North-American and Peruvian myth, "from tree or stone" (*Odyssey*, xix. 163). This view was common among the Greeks, who boasted of being autochthonous. The Cephisian marsh was one scene of man's birth according to a fragment of Pindar, who mentions Egyptian and Libyan legends of the same description.

Myths of the Arts of Life.—These are almost unanimously attributed to "culture-heroes," beings theriomorphic or anthropomorphic, who, like Pund-jel, Qat, Quawteaht, Prometheus, Manabozho, Quetzalcoatl, Cagn, and the rest, taught men the use of the bow, the processes (where known) of pottery, agriculture (as Demeter), the due course of the mysteries, divination, and everything else they knew. Commonly the teacher disappears mysteriously. He is often regarded by modern mythologists as the sun.

Star Myths.—"The stars came otherwise," says Mr Browning's Caliban. In savage and civilized myths they are usually metamorphosed men, women, and beasts. In Australia, the Pleiades, as in Greece, were girls. Castor and Pollux in Greece, as in Australia, were young men. Our Bear was a bear, according to Charlevoix and Lafitan, among the North-American Indians; the Eskimo, according to Egede, who settled the Danish colony in Greenland, regarded the stars "very nonsensically," as "so many of their ancestors;" the Egyptian priests showed Plutarch the stars that had been Isis and Osiris. Aristophanes, in the *Pax*, shows us that the belief in the change of men into stars survived in his own day in Greece. The Bushmen (Bleek) have the same opinion. The *Satapatha-Brahmana* (*Sacred Books of the East*, xii. 284) shows how Prajapati, in his incestuous love, turned himself into a roebuck, his daughter into a doe, and how both became constellations. This is a thoroughly good example of the savage myths (as in Peru, according to Acosta) by which beasts and anthropomorphic gods and stars are all jumbled together.[3] The *Rig-Veda* contains examples of the idea that the good become stars.

Solar and Lunar Myths.—These are universally found, and are too numerous to be examined here. The sun and moon, as in the Bulgarian ballad of the *Sun's Bride* (a mortal girl), are looked on as living beings. In Mexico they were two men, or gods of a human character who were burned. The Eskimo know the moon as a man who visits earth, and, again, as a girl who had her face spotted by ashes which the Sun threw at her. The Khasias make the sun a woman, who daubs the face of the moon, a man. The Homeric hymn to Helios, as Mr Max Müller observes, "looks on the sun as a half-god, almost a hero, who had once lived on earth." This is precisely the Bushman view; the sun was a man who irradiated light from his armpit. In New Zealand and in North America the sun is a beast, whom adventurers have trapped and beaten. Medicine has been made with his blood. In the Andaman Islands the Sun is the wife of the Moon (*Jour. of Anth. Soc.*, 1882). Among aboriginal tribes in India (Dalton, p. 186) the Moon is the Sun's bride; she was faithless and he cut her in two, but occasionally

[1] *Black Yajur-Veda* and *Satapatha-Brahmana*; Muir, i. 52.

[2] Aristophanes, *Aves*, 686; *Etym. Magn.*, s.v. Ἰκόνιον. Pausanias saw the clay (Paus. x. iv.). The story is also quoted by Lactantius from Hesiod.

[3] See also *Vishnu Purana*, i. 131.

lets her shine in full beauty. The Andaman Islanders account for the white brilliance of the moon by saying that he is daubing himself with white clay, a custom common in savage and Greek mysteries. The Red Men accounted to the Jesuits for the spherical forms of sun and moon by saying that their appearance was caused by their bended bows. The Moon in Greek myths loved Endymion, and was bribed to be the mistress of Pan by the present of a fleece, like the Dawn in Australia, whose unchastity was rewarded by a gift of a red cloak of opossum skin. Solar and lunar myths usually account for the observed phenomena of eclipse, waning and waxing, sunset, spots on the moon, and so forth, by various mythical adventures of the animated heavenly beings. In modern folk-lore the moon is a place to which bad people are sent, rather than a woman or a man. The mark of the hare in the moon has struck the imagination of Germans, Mexicans, Hottentots, Cingalese, and produced myths among all these races.[1]

Myths of Death.—Few savage races regard death as a natural event. All natural deaths are supernatural with them. Men are assumed to be naturally immortal, hence a series of myths to account for the origin of death. Usually some custom or "taboo" is represented as having been broken, when death has followed. In New Zealand, Maui was not properly baptized. In Australia, a woman was told not to go near a certain tree where a bat lived; she infringed the prohibition, the bat fluttered out, and men died. The Niugphoos were dismissed from paradise, and became mortal, because one of them bathed in water which had been tabooed (Dalton, p. 13). In the *Atharva-Veda*, Yama, like Maui in New Zealand, first "spied out the path to the other world," which all men after him have taken. In the *Rig-Veda* (x. 14), Yama "sought out a road for many." In the Solomon Islands (*Jour. Anth. Inst.*, Feb. 1881), "Koevari was the author of death, by resuming her cast-off skin." The same story is told in the Banks Islands. In the Greek myth (Hesiod, *Works and Days*, 90), men lived without "ill diseases that give death to men" till the cover was lifted from the forbidden box of Pandora. As to the myths of Hades, the place of the dead, they are far too many to be mentioned in detail. In almost all the gates of hell are guarded by fierce beasts, and in Ojibway, Finnish, Greek, Papuan, and Japanese myths no mortal visitor may escape from Hades who has once tasted the food of the dead.

Myths of Fire-stealing.—Those current in North America (where an animal is commonly the thief) will be found in Bancroft, vol. iv. The Australian version, singularly like one Greek legend, is given by Brough Smyth. Stories of the theft of Prometheus are recorded by Hesiod, Æschylus, and their commentators. Muir and Kuhn may be consulted for Vedic fire-stealing.

Heroic and Romantic Myths.—In addition to myths which are clearly intended to explain facts of the universe, most nations have their heroic and romantic myths. Familiar examples are the stories of Perseus, Odysseus, Sigurd, the Indian epic stories, the adventures of Ilmarinen and Wainamoinen in the *Kalewala*, and so forth. To discuss these myths as far as they can be considered apart from divine and explanatory tales would demand more space than we have at our disposal. It will become evident to any student of the romantic myths that they consist of different arrangements of a rather limited set of incidents. These incidents have been roughly classified by Von Hahn.[2] We may modify his arrangement as follows.

There is (1) the story of a bride or bridegroom who transgresses a commandment of a mystic nature, and disappears as a result of the sin. The bride sins as in Eros and Psyche, Freja and Oddur, Pururavas and Urvasi.[3] The sin of Urvasi and Psyche was seeing their husbands—naked in the latter case. The sin was against "the manner of women." Now the rule of etiquette which forbids seeing or naming the husband (especially the latter) is of the widest distribution. The offence in the Welsh form of the story is naming the partner—a thing forbidden among early Greeks and modern Zulus. Presumably the tale (with its example of the sanction) survives the rule in many cases. (2) "Penelope formula." The man leaves the wife and returns after many years. A good example occurs in Chinese legend. (3) Formula of the attempt to avoid fate or the prophecy of an oracle. This incident takes numerous shapes, as in the story of the fatal birth of Perseus, Paris, the Egyptian prince shut up in a tower, the birth of Œdipus. (4) Slaughter of a monster. This is best known in the case of Andromeda and Perseus. (5) Flight, by aid of an animal usually, from cannibalism, human sacrifice, or incest. The Greek example is Phrixus, Helle, and the ram of the golden fleece. (6) Flight of a lady and her lover from a giant father or wizard father. Jason and Medea furnish the Greek example. (7) The youngest brother the successful adventurer, and the head of the family. We have seen the example of Greek mythic illustrations of "jungsten-recht," or supremacy of the youngest, in the Hesiodic myth of Zeus, the youngest child of Cronus. (8) Bride given to whoever will accomplish difficult adventures, or vanquish girl in race. The custom of giving a bride without demanding bride-price, in reward for a great exploit, is several times alluded to in the *Iliad*. In Greek heroic myth Jason thus wins Medea, and (in the race) Milanion wins Atalanta. In the *Kalewala* much of the Jason cycle, including this part, recurs. The rider through the fire wins Brunhild but this may belong to another cycle of ideas. (9) The grateful beasts, who, having been aided by the hero, aid him in his adventures. Melampus and the snakes is a Greek example. This story is but one specimen of the personal human character of animals in myths, already referred to the intellectual condition of savages. (10) Story of the strong man and his adventures, and stories of the comrades Keen-eye, Quick-ear, and the rest. Jason has comrades like these, as had Ilmarinen and Heracles, the Greek "strong man." (11) Adventure with an ogre, who is blinded and deceived by a pun of the hero's. Odysseus and Polyphemus is the Greek example. (12) Descent into Hades of the hero. Heracles, Odysseus, Wainamoinen in the *Kalewala*, are the best-known examples in epic literature. These are twelve specimens of the incidents, to which we may add (13) "the false bride," as in the poem of *Berte aux grans Piés*, and (14) the legend of the bride said to produce beast-children. The belief in the latter phenomenon is very common in Africa, and in the *Arabian Nights*, and we have seen it in America.

Of these formulæ (chosen because illustrated by Greek heroic legends)—(1) is a sanction of barbarous nuptial etiquette; (2) is an obvious ordinary incident; (3) is moral, and both (3) and (1) may pair off with all the myths of the origin of death from the infringement of a taboo or sacred command; (4) would naturally occur wherever, as on the west coast of Africa, human victims have been offered to sharks or other beasts; (5), the story of flight from a horrible crime, occurs in some stellar myths, and is an easy and natural invention; (6), flight from wizard father or husband, is found in Bushman and Namaqua myth, where the husband is an elephant; (7), success of youngest brother, may have been an explanation and sanction of "jungsten-recht,"—Maui in New Zealand is an example, and Herodotus found the story among the Scythians; (8), the bride given to successful adventurer, is consonant with heroic manners as late as Homer; (9) is no less consonant with the belief that beasts have human sentiments and supernatural powers; (10), the "strong man," is found among Eskimo and Zulus, and was an obvious invention when strength was the most admired of qualities; (11), the baffled ogre, is found among Basques and Irish, and turns on a form of punning which inspires an "ananzi" story in West Africa; (12), descent into Hades, is the natural result of the savage conception of Hades, and the tale is told of actual living people in the Solomon Islands and in New Caledonia; Eskimo Angekoks can and do descend into Hades,—it is the prerogative of the necromantic magician; (13), "the false bride", found among the Zulus, does not permit of such easy explanation,—naturally, in Zululand, the false bride is an animal; (14), the bride accused of bearing beast-children, has already been disposed of; the belief is inevitable where no distinction worth mentioning is taken between men and animals. English folk-lore has its woman who bore rabbits.

The formulæ here summarized, with others, are familiar in the märchen of Samoyeds, Zulus, Bushmen, Hottentots, and Red Indians.[4] For an argument intended to show that Greek heroic myths may be adorned and classified marchen, in themselves survivals of savage fancy, see *Fortnightly Review*, May 1872, "Myths and Fairy Tales." The usual explanation is that märchen are degenerate heroic myths. This does not explain the marchen of African, and perhaps not of Siberian races.

In this sketch of mythology that of Rome is not included, because its most picturesque parts are borrowed from or adapted into harmony with the mythology of Greece. Japanese, Chinese, and Persian matters are omitted from want of information, and because of the extreme obscurity of the subject. Greece, India, and Scandinavia will supply a fair example of Aryan mythology (without entering on the difficult Slavonic and Celtic fields).

There is perhaps no single work which contains a good comparative view of civilized and savage mythologies. Tylor's *Primitive Culture* comes nearest to what a reader interested in truly comparative mythology desires. As a rule, writers like Cox, Gubernatis, and other "elemental" mythologists lay little stress on non-Aryan stories. Gubernatis's *Zoological Mythology* and Cox's *Mythology of the Aryan People* must be consulted with caution. Schwartz, in his *Der Ursprung der Mythologie*, has got hold of a correct idea (the belief in meteoric animals), but he works his idea too hard. The writings of Max Muller, Muir's *Ancient Sanskrit Texts*, and other standard works have already been repeatedly quoted. The old writers, like Bryant, are useless, except for occasional references to ancient authorities. There are many useful references in Mr Brown's *Great Dionysiak Myth*, but the reasonings need not be adopted. As a rule the German treatises adopt various forms of the "meteorological" and "solar" hypotheses. (A. L.)

N

N denotes the dental nasal in all the languages in which our alphabet is used. But the sound which we call the dental nasal varies slightly in different languages according to the position of the point of the tongue. This may be pressed against the backs of the teeth; and then we have a true "dental" sound. But the point of the tongue may [illegible] against the front part of the [illegible] behind the gums; and it is in this way that our English n is formed.

But this one letter N, [illegible] of nasal sounds. It has been already pointed out (see letter M) that there are in every language [illegible] different parts of the mouth [illegible] Each of these [illegible] the different position of the uvula [illegible] through the pharynx into the nostrils [illegible] the whole of the [illegible] behind it [illegible] In some [illegible] European language has more than [illegible] different languages [illegible] French, which will be described below.

The guttural nasal is heard in "singer," "finger," "hunger," [illegible] and in "ink," "finger," &c. In English, when the sound occurs at the end of a word, it is represented by ng, as "hang," "sing," [illegible] also when medial, as in the derivatives "hanger," "singer." It would be convenient if, as has often been proposed, the [illegible] symbol were employed for this sound. The sound is heard in German as well as in English; but in French it is unknown. On the other hand, the front palatal nasal is heard in the French "Boulogne," Italian "Campagna," Spanish "año," [illegible] the diacritical mark being always used in Spanish; it is not known with us; but its position in the mouth is shown by that of the corresponding closed consonants, English ch and j, and of the fricative consonant of the same class, which is y. The peculiar class of sounds called "cerebral" in Sanskrit was formed by turning the point of the tongue a little backward toward the top of the palate; of these the nasal was by far the most frequent. Our English "dental" lies between the cerebral and the true "dentals," for which (as in India) the tongue actually touches the teeth,—our dental being of the kind already mentioned, in which the tongue does not come farther forward than the front palate.

From what has been said, it will appear that the nasals might be called nasalized consonants. The guttural nasal is *g* nasalized; the dental nasal is *d* nasalized; part of the voice in each case is diverted from the mouth through the nostrils, and some nasal sound is already heard while the passage through the mouth is closed by the tongue, or by the lips for the production of the labial nasal; but the complete nasal sound is not heard till the block of the tongue or of the lips is removed, exactly as in the production of *g*, *d*, or *b*. But it is possible to nasalize vowels as well as to nasalize consonants. The position of the uvula can be altered when the mouth is set for sounding the vowel *a* just as well as when it is set for the sound of *g*; and then instead of the pure *a*-sound we get one of a nasal quality; so instead of the final consonant sound of "hag" we get the nasalized guttural in "hang." These nasalized vowels are unknown to us in England; and this is the reason why we find so much difficulty in pronouncing them in French. An Englishman learning French will always begin by pronouncing "en" as if it were "eng," and "on" as if it were "ong." But the French "en" is not the vowel *e* plus the guttural nasal *ng*; it is the vowel *e* nasalized.

It is probable, though not provable, that nasal vowels were used in Latin. The evidence lies in the varying spelling of words like "censor" and "cesor," "consul" and "cosul"; neither is right, but each seems to be an attempt to avoid an error; "censor" is a protest against sounding the word as if it were pure *e*; and "cesor" against sounding it as *e* + *n*. Again, the Latin has "con-ficere," but "com-ponere"; now *f* and *p* are both labials, and therefore we should expect the same treatment of the final *n* in "con" before each; probably the *n* marked a nasal vowel (on) before a fricative consonant, whereas the *m* was a true nasal consonant before the closed consonant *p*. Cicero's doctrine (*Orat.* 159) that the vowel *i* is naturally long in "in-sanus," "in-felix," &c., but short in "in-doctus," points to the same conclusion—that the *n* before *s* and *f* marked a long nasalized vowel. Lastly, we have the spelling of Greek words like θησαυρός as "thensaurus" in Latin; it is improbable that the *n* here was the full consonant.

It is not unlikely that the appearance and non-appearance of the nasal in the dialects of the same language is due to an original nasalized vowel which has in one case disappeared, in the other has passed into a vowel followed by a nasal. Thus in German we find "sanft" corresponding to English "soft," "gans" to "goose," &c. But the vowel has been modified in such cases in compensation for the loss of its original nasal quality.

The phenomenon of the so-called "parasitic" nasal arises from careless pronunciation: before sounding a closed consonant (like *g*) the uvula is not sufficiently raised, and so a nasal of the same class is heard before the *g*, as in "nightingale" (compare German "nachtigal"). Yet more common is the development by the nasal itself of a parasitic closed consonant of its own class; many such have long been firmly established, as in the words "*sound*" (Middle English "soun," like French "son," Latin "sonus"), "thun*d*er" (A.S. "thunor"), still rightly pronounced in the north of England as "thunner"; but "gown*d*," "sing-*g*ing," though familiar enough, have not yet made their way into polite speech. These parasitic sounds are also due to careless pronunciation; if the passage through the nostrils be not kept open till the articulating organs of the mouth have separated, the nasal quality at the end of the sound is lost, and the closed consonant must follow. There has been an odd loss of *n* at the beginning of several English words which has often

been noted. It arises from our double form of the indefinite article "a" and "an." Sometimes the "a" has abstracted the "n" from the beginning of the noun: thus "a nadder" has turned into "an adder," "a napron" into "an apron," "a nauger" into "an auger." On the other hand the letter has had one compensatory gain: "an ewt" (eft) has turned into "a newt." (J. P.)

NABATÆANS, a famous people of ancient Arabia, whose settlements in the time of Josephus (*Ant.*, i. 12, § 4; comp. Jerome, *Qu. in Gen.* xxv.) gave the name of Nabatene to the border-land between Syria and Arabia from the Euphrates to the Red Sea. The language of Josephus suggests, and Jerome, apparently following him, directly affirms, that the name is identical with that of the Ishmaelite tribe of Nebaioth (נְבָיוֹת, Gen. xxv. 13; Isa. lx. 7), which in later Old Testament times had a leading place among the northern Arabs, and is associated with Kedar much as Pliny v. 11 (12) associates *Nabatæi* and *Cedrei*. The identification is still followed by many scholars, but is rendered uncertain by the fact that the name Nabatæan is properly spelled with ṭ not t (נבטו on the inscriptions, Arabic *Nabaṭ*, *Nabîṭ*, &c.). Thus the history of this remarkable people cannot with certainty be carried back beyond 312 B.C., at which date they were attacked without success by Antigonus in their mountain fortress of Petra. They are described by Diodorus (xix. 94 *sq.*) as being at this time a strong tribe of some 10,000 warriors, pre-eminent among the nomadic Arabs, eschewing agriculture, fixed houses, and the use of wine (which were forbidden on pain of death), living on flesh and milk, and drinking water sweetened with manna, but adding to pastoral pursuits a considerable and profitable trade with the seaports in myrrh and spices from Arabia Felix, as well as a trade with Egypt in bitumen from the Dead Sea used in the preparation of mummies. Their arid country was the best safeguard of their cherished liberty; for the bottle-shaped cisterns for rain-water which they excavated in the rocky or argillaceous soil were carefully concealed from invaders. Petra or Selaʿ was the ancient capital of Edom; the Nabatæans must have occupied the old Edomite country, and succeeded to its commerce, after the Edomites took advantage of the Babylonian captivity to press forward into southern Judæa. This migration, the date of which cannot be determined, also made them masters of the shores of the Gulf of ʿAḳaba and the important harbour of Elath. Here, according to Agatharchides (*Geog. Gr. Min.*, i. 178), they were for a time very troublesome, as wreckers and pirates, to the reopened commerce between Egypt and the East, till they were chastised by the Greek sovereigns of Alexandria.

Tenacious as they were of the nomad usages of their ancestors, the Nabatæans had already some tincture of foreign culture when they first appear in history. That culture was naturally Aramaic; they wrote a letter to Antigonus "in Syriac letters," and Syriac continued to be the language of their coins and inscriptions when the tribe grew into a kingdom, and profited by the decay of the Seleucids to extend its borders northward over the more fertile country east of the Jordan. They occupied the Ḥaurán, and about 85 B.C. their king Aretas (Ḥáritha) became lord of Damascus and Cœle Syria. Allies of the first Hasmonæans in their struggles against the Greeks, they became the rivals of the Judæan dynasty in the period of its splendour, and a chief element in the disorders which invited Pompey's intervention in Palestine. The Roman arms were not very successful against the sons of the desert (expedition of Scaurus, 63 B.C.); King Arétas retained his whole possessions, including Damascus, as a Roman vassal.[1]

[1] Compare 2 Cor. xi. 32. The Nabatæan Aretas or Æneas there mentioned reigned from 7 B.C. to 40 A.D. or thereby.

As "allies" of the Romans the Nabatæans continued to flourish throughout the first Christian century. Their power extended far into Arabia, particularly along the coast of the Red Sea; and Petra was a meeting-place of many nations, though the importance of its commerce was diminished by the rise of the Eastern trade-route from Myoshormus to Coptus on the Nile. Under the Roman peace they lost their warlike habits, and were a sober, acquisitive, orderly people, wholly intent on trade. They had now agriculture and houses of stone, and were not unacquainted with foreign luxuries and arts (Strabo, xvi. 4). Such a people might have long been a valuable bulwark between Rome and the wild hordes of the desert but for the short-sighted cupidity of Trajan, who reduced Petra and broke up the Nabatæan nationality (105 A.D.). The new Arab invaders who soon pressed forward into their seats found the remnants of the Nabatæans transformed into *fellâḥîn*, and speaking Aramaic like their neighbours. Hence Nabatæans became the Arabic name for Aramæans, whether in Syria or ʿIrâḳ, a fact which was misinterpreted by Quatremère into a theory that the Nabatæans were originally Aramæan immigrants from Babylonia. More recent inquiry has shown this view to be quite false. The Nabatæans were true Arabs—as the proper names on their inscriptions show—who came under the influence of Aramæan civilization. See especially Nöldeke in *Z. D. M. G.*, xvii. 705 *sq.*, xxv. 122 *sq.*

For the inscriptions and coins of the Nabatæans consult De Luynes in *Revue Numism.*, 1858; Levy in *Z. D. M. G.*, xiv. 363 *sq.*; De Vogüé, *Mél. d'Arch. Or.*, 1868, *Syrie Centrale*, 1866–77, and *Inscr. Sémitiques*, 1868–77. The character of De Vogüé's inscriptions from the Haurân appears to be the parent of the Cufic Arabic. The so-called *Faláḥa Nabaṭíya*, or "Nabatæan agriculture," which professes to be an Arabic translation by Ibn-Waḥshiya from an ancient Nabatæan source (MSS. in Leyden and elsewhere), is a forgery of the 10th century. See Gutschmid in *Z. D. M. G.*, xv. 1 *sq.*; and Nöldeke, *Ibid.*, xxix. 445 *sq.*

NABHA, or Narbal, one of the Cis-Sutlej states in the Punjab, India, lying between 30° 17′ and 30° 40′ N. lat., and between 75° 50′ and 76° 20′ E. long., has an area of 863 square miles, with a population in 1881 of 261,824. The first relations of the state with the British were in 1807–8, when the rájá applied for and obtained protection against the threatened encroachments of Ranjit Sinh. During the mutiny in 1857 this chief showed distinguished loyalty, and was rewarded by grants of territory to the value of over £10,000. The rájá is a Sikh of the Sidhu Ját tribe; he has full powers of life and death over his subjects, and has an estimated annual revenue of £65,000. The chief products of the state are sugar, cereals, cotton, and tobacco.

NABULÚS, or Nablús. See Shechem.

NADÍM. Abulfaraj ibn Isḥáḳ of Baghdad, known as Ibn abí Yaʿḳúb al-Nadím (*ob.* 995 A.D.), is the author of one of the most interesting works in Arabic literature, the *Fihrist*, or "list of the books of all nations that were to be found in Arabic," with notices of the authors and other particulars, carried down to the year 377 A.H. (987–88 A.D.). A note in the Leyden MS. places the death of the author eight years later. Of his life we know nothing; the name Nadím belonged to a distinguished family of Persian origin. The oldest Arabic scholars, of whose works comparatively little has been preserved to us, had a much wider range of interest than their successors. Even then Islám and the Korán were the centre of all study; but curiosity was not limited by religious scruples; men were eager to know the wisdom and the literature of all nations and sects; the free thought which was afterwards so sternly suppressed in the reaction of orthodoxy towards the close of the 9th century lifted men above narrow prejudices. The work of Al-Nadím gives us a complete picture of the most active intellectual period of the Arab

empire. He traces the rise and growth of philology and belles-lettres, of theology, orthodox and heretical, of law and history, of mathematics and astronomy, of medicine and alchemy; he does not despise the histories of knights errant, the fables of Kalíla and Dimna, the facetiæ of the "boon companions," the works of magic and divination. But to us no part of his work is more interesting than his account of the beliefs of sects and peoples beyond Islâm. Here, fortunately, still more than in other parts of his work, he goes beyond the functions of the mere cataloguer; he tells what he learned of China from a Christian missionary of Najrán, of India from a description of its religion compiled for the Barmecide Yahya; his full accounts of the Sabians of Harrán and of the doctrines of Mani[1] are of the very first importance for the historian of Asiatic religions.

The *Fihrist* was much pillaged by later writers, but the author was sedulously ignored, and MSS. of his work are very scarce. Hottinger possessed one (now lost), and used it in his *Historia Orientalis*. There are others (all imperfect) at Paris, Leyden, and Vienna; a small part of the book is altogether lost. Flügel published an abstract of the work in *Z. D. M. G.*, xiii. (1859): his edition, with notes, appeared posthumously (vol. i., text, Leipsic, 1871; vol. ii., notes, 1872).

NADIR SHAH. See PERSIA.

NADIYÁ, or NUDDEA, a district in the lieutenant-governorship of Bengal, lying between 22° 52′ 33″ and 24° 11′ N. lat., and between 88° 11′ and 89° 24′ 41″ E. long., bounded on the N. by Rájsháhí, on the E. by Pabná and Jessor, on the S. by the 24 Parganás, and on the W. by Húglí, Bardwán, Bírbhúm, and Murshídábád districts, with an area of 3404 square miles. It is emphatically a district of great rivers. Standing at the head of the Gangetic delta, its alluvial surface, though still liable to periodical inundation, has been raised by ancient deposits of silt sufficiently high to be permanent dry land. Along the entire north-eastern boundary flows the wide stream of the Padmá or Ganges; and all the remaining rivers of the district are offshoots of the great river. The Bhágirathí on the eastern border, and the Jalangi and the Matabhanga meandering through the centre of the district, are the chief of these offshoots, and are called distinctively the "Nadiyá rivers." But the whole surface of the country is interlaced with a network of minor streams, communicating with one another by side channels. All the rivers are navigable in the rainy season for boats of the largest burthen, but during the rest of the year they dwindle down to shallow streams, with dangerous sandbanks and bars.

In former times the Nadiyá rivers afforded the regular means of communication between the upper valley of the Ganges and the seaboard; and much of the trade of the district still comes down to Calcutta by this route during the height of the rainy season. But the lines of the East Indian and Eastern Bengal Railways, with the main stream of the Ganges and the Sundarbans route, now carry by far the larger portion of the traffic.

The census of 1881 returned the population at 2,017,847, of whom 1,146,603 were Mohammedans and 864,773 Hindus. Of the 6439 Christians, 6304 were natives. Krishnagar had 24,477 inhabitants in 1881; and six others had in 1872 a population exceeding 5000:—Sántipur, 28,635; Kushtiá, 9245; Ránághát, 8871; Nadiyá, 8863; Mihrpur, 5562; and Kumárkhálí, 5251. Nadiyá, the ancient capital, was formerly situated on the east bank of the Bhágirathí (which has since changed its course). It has always been celebrated for the sanctity and learning of its pandits. The battlefield of Plassey was situated in this district, but the floods of the Bhágirathí have washed away the scene of that memorable engagement.

Rice is the staple crop, and there are four harvests in the year. Indigo is the chief export staple; but the district was the centre of the indigo riots in 1860, and the industry then received a blow from which it has never recovered. A large proportion of the cultivable area of the district is held on *utbandi* tenure—that is, for a single season only, the rents being assessed according to the outturn of the crop. Floods are common, and frequently cause much damage.

The number of indigo factories is still considerable. Cotton-weaving is carried on, but is everywhere on the decline, especially at the town of Sántipur, where, in the beginning of the century, the Company used to purchase muslin to the annual value of £150,000. Sántipur muslin is still exported to a small extent. Raw date sugar is largely manufactured. The chief exports are indigo, jute, linseed, wheat, pulses and gram, rice, chillies, sugar, and tobacco.

The only institutions in the district worthy of note are the *tols* or indigenous Sanskrit schools. In these *smriti* (Hindu social and religious law) and *nyáya* (logic) are taught by learned pandits to eager pupils. The *tols* consist generally of a mere collection of mud hovels round a quadrangle, where the students live in the most primitive manner, each in his own hut, with his brass water-pot and mat, and seldom any other furniture. A student generally remains at the *tol* for eight or ten years. No fees are charged, and the pandits depend for their livelihood on the presents which their fame as teachers ensures them at religious ceremonies. Most of the *tols* are in Nadiyá town, but there are also a few in the surrounding villages. Their number is rapidly decreasing.

The district revenue in 1880–81 amounted to Rs. 1,654,813, Rs. 1,051,776 being derived from the land-tax. Education was afforded in 1877 by 897 schools, attended by 28,489 pupils. The principal educational institution is the Government college at Krishnagar. The average annual temperature is 77° Fahr.; the average annual rainfall about 65 inches. Besides remittent and intermittent fevers, which cause very great mortality, small-pox, diarrhœa, dysentery, and cholera are prevalent. Cattle disease is common.

NÆVIUS, GNÆUS, is the second in order of time among the creators of Latin literature. He had made his appearance as an author within five years after the first dramatic representation of Livius Andronicus; he was some ten or fifteen years older than Plautus, and preceded Ennius by a generation. As distinguished from Livius he was a native Italian, not a Greek; he was also a writer of original power, not a mere adapter or translator. If it was due to Livius that the forms of Latin literature were, from the first, moulded on those of Greek literature, it was due to Nævius that much of its spirit and substance was of native growth. Long before the formal recognition of literature in Rome, which dated from the year 240 B.C., there had existed various kinds of inartistic composition, written or spoken, in Saturnian verse. The most important of these were satiric and dramatic medleys, known by the name of *saturæ*, and commemorative verses in praise of eminent men, which were first sung at funeral banquets, and seem afterwards to have been preserved among family records. The fact that Nævius wrote his most important poem in Saturnian verse, the disparaging reference made to him by Ennius as the writer of verses like those of the old native "Fauni and Vates," the claim which he makes in his epitaph to be the last purely Latin poet, the political satire which he introduced into his comedies, the national and commemorative character of his epic poem, all point to him as a medium of connexion between the nameless authors of these satiric and commemorative verses and the recognized authors of Roman comedy, satire, and even epic poetry.

Though the fragments preserved from his numerous writings are few and inconsiderable, yet they corroborate the impression derived from ancient testimony that he was a man of originality and force of mind, and of a bold and vigorous character. The impulse which he sought to give to Latin literature was somewhat antagonistic to that actually given by Ennius; and either the greater genius and richer culture of the latter or his greater adaptation to his times determined that his influence should be predominant. Probably the genius of Ennius was the higher creative force; it was more in harmony with the serious Roman spirit, and with the grandeur of Roman institutions; it more naturally allied itself with the aristocratic influence which was predominant in the state for two generations after the death of Nævius; it was also more

[1] The former translated in Chwolson's *Ssabier und Ssabismus*, vol. ii., the latter in Flügel's *Mani, seine Lehre und seine Schriften*, 1862.

tecture, ornament the town; but the palace, built of black basalt, profusely ornamented with wood carving, was burnt down in 1864, and only the great gateway now remains. The tombs of the Bhonslá kings lie to the south of the city.

Nágpur does a large and increasing trade, the chief imports being wheat and other grain, salt, country cloth, European piece goods, silk, and spices. Cloth forms the chief article of manufacture and export. The finer fabrics of Nágpur have long been famous, and are still, in spite of the competition of English stuffs, in great request. Most of the public offices are in the station of Sítábaldí.

NAGY-KÖRÖS (*i.e.*, Great Körös) is a town, or rather an overgrown village, in Hungary, in the district and 50 miles to the south-west of Pesth. It lies in the midst of a sandy plain, and is a station on the railway from Pesth to Temesvar. In 1880 it contained 22,769 inhabitants, chiefly Protestants, who are engaged in wine-culture and the rearing of cattle and sheep. Its gymnasium is esteemed one of the best schools in Hungary.

NAGY-VÁRAD. See GROSSWARDEIN.

NAHARRO, BARTOLOMÉ DE TORRES, a Spanish dramatist of the period immediately preceding that of Cervantes and Lope de Vega, born at Torres in the neighbourhood of Badajoz, was for some time a captive in Algiers, and after receiving his freedom visited the court of Leo X. at Rome. Here his satirical pen excited such hostility that he was compelled to fly to Naples, where he lived for some time under the protection of Fabricio Colonna, and where he published his *Propaladia* in 1517. He died in poverty and obscurity; the time and place are unknown. See DRAMA, vol. vii. p. 420.

NAHUM. "The book of the vision of Nahum the Elkoshite" (נַחוּם, "compassionate"), which stands seventh among the minor prophets, is entirely directed against Nineveh, and predicts the utter destruction of the bloody and rapacious city, its empire, and its gods by the tardy but sure and irresistible vengeance of Jehovah. The fall of Nineveh is the deliverance of Judah; Jehovah, so terrible to His adversaries, so unfailing in His righteous judgments, is a sure and gracious defender to them that take refuge with Him. It appears therefore that, when the prophet wrote, the Judæans were still suffering from Assyrian oppression, perhaps even from present or recent invasion, for in i. 15 [ii. 1] he speaks of the annual feasts and the sacrifices of the sanctuary as disturbed by the "wicked one" passing through the land. It is not, however, from a merely patriotic standpoint that Nahum regards the Assyrian harlot as Jehovah's enemy; she is the enemy of mankind, who sells all nations through her witchcrafts and whoredoms—that is, in the strength of her heathenish religion (iii. 4),—and she shall perish with none to pity her, for all have suffered continually from the wickedness of the ruthless empire. The exordium in chap. i., which depicts Jehovah as the jealous and avenging God, is a noble utterance of faith in the righteousness which rules in the world's history. The other two chapters are entirely occupied with the catastrophe of Nineveh; the battle without and within the walls is described with great poetic force, not in finished pictures but with broad effective strokes and daring imagery, and apparently with some local knowledge, though the latter is hardly so detailed as to justify the conclusion that the prophet had himself seen the imperial city. It might be argued on the same principle that he had also seen No-Ammon or Thebes, a description of the sack of which forms an episode in chap. iii. 8 *sq.* The reference here seems to be to the taking of No by Assurbanipal (G. Smith, *Hist. of Assurbanipal*, 55, 70; Schrader, *K. A. T.*, 2d ed., p. 450) about 660 B.C. —an event only known from the Assyrian monuments. Nahum must have prophesied after this date, probably not long after, that is, in the troublous times of Manasseh, which agrees well with i. 15. To suppose that his prophecy was occasioned by the actual approach of the Medes to destroy Nineveh, or by one of the earlier campaigns which preceded their final success, is arbitrary; for the judgment is predicted on general principles of divine justice, and there is no indication that the prophet knew what nation was to execute it. His descriptions, though pictorially vivid, are historically quite vague. The details of the decadence of the Assyrian empire are in truth so obscure that to search for the immediate occasion of the prophecy is mere guesswork.

The name Elkoshite (אֶלְקֹשִׁי, in the LXX. Ἐλκεσαῖος—the pronunciation therefore is uncertain) denotes the prophet's home or birthplace. Jerome's mention of a ruined "viculus Elcesi" in Galilee stands quite alone; Hitzig supports the idea that the prophet was a Galilæan by the name Capernaum, which probably means "village of Nahum," but of what Nahum we do not know. The confused account by R. Jos. Schwarz (*D. Heil. Land*, p. 149) of a grave shown as that of the prophet Nahum an hour north of Tiberias lacks confirmation. Internal evidence leads us rather to conclude that Nahum was a man of Judah, and John vii. 52 appears to show that he was not held to be a Galilæan in the time of Christ, when the fashion of localizing tombs of prophets was already in full force (Matt. xxiii. 29). Later tradition associated Nahum with the region against which he prophesied, and in the 12th century Benjamin of Tudela visited his synagogue at Mosul and his tomb in Babylonia. It was probably under Christian influence that the site of this tomb was ultimately fixed at Alkôsh, the seat of the later Nestorian patriarchs, near the convent of Rabban Hormizd, a few miles north of Mosul, where it is now reverenced by Christians, Moslems, and Jews. The sepulchre is a simple plaster box without signs of antiquity (Layard, *Nineveh*, i. 233). The history of this identification of Elkosh is obscure; it is mentioned in the 16th century by Masius (ap. Assemani, *B. O.*, i. 525), as also in two Nestorian MSS. written at Alkôsh by the same scribe in 1709 (Wright, *Cat.*, 1068) and 1713 (Assem., iii. i. 352); it seems, moreover, to be implied in a gloss of Bar Ali, given by Payne Smith (*Thes. Syr.*, 221), but not in Hoffmann's edition. On the other hand no very early notice either of the tomb or of the place has yet been found. Alkôsh, but not the Nahum legend, is mentioned in a poem of the 11th century in Cardahi, *Liber Thesauri* (Rome, 1875); the same author places one Israel of Alkôsh in the 8th century, but the date is questionable (see Nöldeke in *Z. D. M. G.*, xxxi. 165). The grave is undoubtedly a fabrication, and the evidence is not favourable to Ewald's conjecture that the name is ancient and the place really the city of Nahum. His further conjecture that some difficult words in Nahum may be Assyrian has not been confirmed by students of the inscriptions.

Literature.—The commentaries on the minor prophets; O. Strauss, *Nahumi de Nino vaticinium*, 1853. For a list of other books see Reuss, *Gesch. d. A. T.*, p. 369. (W. R. S.)

NAIADS. See NYMPHS.

NAILS. A nail is a headed pin or spike of metal, commonly of iron. The primary and principal use of nails is in wood work (joinery and carpentery), but they are also employed in upholstery, shoemaking, saddlery, slating, sheet-metal working, horse-shoeing, and numerous other trades. The consumption in all civilized communities is enormous, but it is exceptionally great where timber houses and wooden erections generally prevail, as in the United States of America, and in many British colonies. Size, form of head, nature of point, and special uses all give names to different classes of nails. Thus we have the names tacks, sprigs, and brads for very small nails; rose, clasp, and clout, according to the form of head; and flat points or sharp points according to the taper of the spike. Arranged according to the manner in which they are manufactured, nails may fall into four principal classes: —(1) ordinary or hand-wrought nails; (2) machine-wrought and cut nails; (3) wire or French nails; and (4) cast nails. The nailer handicraft was at one time a great industry in the country around Birmingham, and to this day in conjunction with chain-making it constitutes an important though declining trade. It is essentially a family industry, carried on in the meanest of workshops, with a very few simple blacksmith's tools and appliances. The nails are forged from nail-rods heated in a small

capable of *assimilating* the Greek culture, which was the formative element in the literary art of the Romans. Yet the racy popular spirit of Nævius gained for him admirers even in the Augustan age, and Cicero represents the great master of Latin oratory, Crassus, as the highest compliment he could pay to the pure idiomatic speech of his mother-in-law, Lælia, comparing it to the style of Nævius and Plautus. Though a richer vein of imaginative feeling was introduced into the Latin language and literature by Ennius, yet much was lost in their subsequent development by the partial suppression of the aggressive boldness and freedom of Nævius, as well as of the exuberant mirth and humour of Plautus.

There is great uncertainty in regard to the facts and dates of the life of Nævius. From the expression of Gellius characterizing his epitaph as written in a vein of "Campanian arrogance" it has been inferred that he was born in one of the Latin communities settled in Campania. But the phrase "Campanian arrogance" seems to have been used proverbially for "gasconade"; and, as there was a plebeian *Gens Nævia* in Rome, it is quite as probable that he was by birth a Roman citizen. The strong political partisanship which he displayed in his plays is favourable to this supposition, as is also the active interference of the tribunes on his behalf. On the other side weight must be given to the remark of Mommsen, viz., "the hypothesis that he was not a Roman citizen, but possibly a citizen of Cales or of some other Latin town in Campania, renders the fact that the Roman police treated him so unscrupulously the more easy of explanation." He served either in the Roman army or among the *socii* in the First Punic War, and thus must have reached manhood before the year 241 B.C. We learn from Cicero that he lived to a good old age, and that he died in exile about the end of the 3d century B.C. The date of his birth may be thus fixed with approximate probability about the year 265 B.C. No particulars of his military service are recorded. Sicily was the great battlefield of the combatants during the latter years of the war. No important Sicilian city was without its theatre, and it seems legitimate to connect the new taste for regular dramatic performances (and especially for tragedy, to which there was nothing corresponding among the Italian races) developed at Rome immediately after the conclusion of the First Punic War with the Sicilian experiences of the Roman and allied armies serving in the war. Another important influence in Roman literature and Roman belief which first appeared in the epic poem of Nævius also had its origin in Sicily, viz., the recognition of the mythical connexion of Æneas and his Trojans with the foundation of Rome. The origin of this belief may probably be attributed to the Sicilian historian Timæus; but the contact of the Romans and Carthaginians in the neighbourhood of Mount Eryx may have suggested that part of the legend which plays so large a part in the *Æneid*, which brings Æneas from Sicily to Carthage and back again to the neighbourhood of Mount Eryx. The actual collision of Phœnician and Roman on the western shores of Sicily, of which Nævius may well have been a witness, if it did not originate, gave a living interest to the mythical origin of that antagonism in the relations of Æneas and Dido.

The career of Nævius as a dramatic author began with the exhibition of a drama in or about the year 235 B.C., and was carried on energetically for thirty years afterwards. Towards the close of this career he incurred the hostility of some of the nobility, especially, it is said, of the family of the Metelli, by the attacks which he made upon them on the stage, and at their instance he was imprisoned,—a circumstance to which Plautus alludes in a passage of the *Miles Gloriosus* (211). After writing two plays during his imprisonment, in which he is said to have apologized for his former rudeness (Gellius, iii. 3, 15), he was liberated through the interference of the tribunes of the commons; but he had shortly afterwards to retire from Rome (in or about the year 204 B.C.) to Utica. The generally received accounts assigned his death to that year; but Cicero (*Brutus*, 15, 60) quotes Varro as an authority for the belief that his life was prolonged beyond that date. It may have been during his exile, when withdrawn from his active career as a dramatist, that he composed or completed his poem on the First Punic War.[1] Probably his latest composition was the epitaph already referred to, also written in Saturnian verse:—

"Immortales mortales flere si foret fas,
Flerent divæ Camenæ Nævium poetam;
Itaque postquam est Orcino traditus thesauro
Obliti sunt Romai loquier lingua Latina."[2]

If, as has been supposed, these lines were dictated by a jealousy of the growing ascendency of Ennius, the life of Nævius must have been prolonged considerably beyond the year 204 B.C., as it was only in that year that Ennius first settled, and began his career as an author, in Rome.

Like Livius, Nævius professed to adapt Greek tragedies and comedies to the Roman stage. Among the titles of his tragedies are *Ægisthus*, *Lycurgus*, *Andromache* or *Hector Proficiscens*, *Equus Trojanus*, &c. We find in the letters of Cicero a reference to a representation of the last-named play at the opening of the theatre of Pompey in 55 B.C.; but it seems to have retained its popularity so long not so much from its dramatic merits as from the scope it afforded for the gratification of the Roman taste for gorgeous spectacles. The few fragments preserved from the tragedies show the first rude beginnings of that artificial poetical phraseology and poetical word-formation which the impulse derived from Greek literature developed in the speech of Latium, and also the more native product of pithy sayings (such as the "laudari a laudato viro," "sero sapiunt Phryges") which had passed into proverbs in the age of Cicero. The national cast of his genius and temper was further shown by his deviating from his Greek originals, and producing at least two specimens of the *fabula prætexta*, one founded on the childhood of Romulus and Remus (*Romulus s. Alimonium Romuli et Remi*), the other called *Clastidium*, which celebrated the contemporary victory in which Marcellus carried off the *spolia opima*.

But it was as a writer of comedy that he was most famous, most productive, and most original. While he is never ranked as a writer of tragedy with Ennius, Pacuvius, or Accius, he is placed in the canon of the grammarian Volcatius Sedigitus third (immediately after Cæcilius and Plautus) in the rank of Roman comic authors. He is there characterized as "Nævius qui fervet," a phrase expressive of his ardent, impetuous character and style. He is also appealed to, along with Plautus and Ennius, as a master of his art in one of the prologues of Terence. His comedy, like that of Plautus, seems to have been rather a free adaptation of his originals than a rude copy of them, as those of Livius probably were, or an artistic copy like those of Terence. The titles of most of them, like those of Plautus, and unlike those of Cæcilius and Terence, are Latin not Greek. Among the few lines preserved from them we find in one the "Laurentines and Prænestines" spoken of, just as we find mention of provincial Italian towns frequently in Plautus. He drew from the writers of the old political comedy of Athens, as well as from the new comedy of manners, and he attempted to make the stage at Rome, as it had been at Athens, an arena of political and personal warfare. A strong spirit of partisanship is recognized in more than one of his fragments; and this spirit is thoroughly popular and adverse to the senatorian ascendency which became more and more confirmed with the progress of the Second Punic War. Besides his attack on the Metelli and other members of the aristocracy, the great Scipio (whose services and world-wide fame he acknowledges) is the object of a censorious criticism on account of a youthful escapade attributed to him. Among the few lines still remaining from his lost comedies, we seem to recognize the idiomatic force and rapidity of movement characteristic of the style of Plautus. There is also found that love of alliteration which is a marked feature in all the older Latin poets down even to Lucretius. In one considerable comic fragment attributed to him,—the description of a coquette,—there is great truth and shrewdness of observation. But we find

[1] Cicero (*De Sen.*, 11) speaks of it as the work of his old age.

[2] "If it were permitted that immortals should weep for mortals, the divine Camenæ would weep for Nævius the poet; for since he hath passed into the treasure-house of death men have forgotten at Rome how to speak in the Latin tongue."

Disquiet in France.

graphy. Never was a great state in a position so untenable and monstrous as France after he quitted the helm. In twenty years of thrilling events, in the emotions first of tragedy and then of epic poetry, the French had forgotten the Bourbon court, when suddenly the old Comte de Provence (under the name of Louis XVIII.) and the Comte d'Artois, Condé and the Duc d'Angoulême, and the Orpheline du Temple reappeared and took possession of the country before even a royalist party had formed itself in France. Politically, indeed, they brought liberty, for they created a parliament where all assemblies had been mute and servile for fourteen years; but they unsettled all domestic affairs, the position of public men, the prospects of the army, the title of estates, in a manner so sudden and intolerable, and that at a moment when the country had suffered conquest from without, that some new convulsion seemed manifestly imminent. Disgraced, bewildered, and alarmed at the same time, the French could think with regret even of the reign of Napoleon. The wholesale massacre of the last two years might have been expected to seem like a bad dream as soon as the spell was snapped, but it began to seem regrettable in comparison with the present humiliation. Another event happened which was like a new revolution. The prisoners and the troops shut up in German fortresses returned to France under the treaty, perhaps not less than 300,000 men. What could be more evident than that if all these soldiers could take the field again, and under Napoleon, France might yet escape the humiliation of a Government imposed by foreigners, and perhaps also recover her lost frontiers. The congress of Vienna entered upon business in September, and from this time a new chapter of politics opened. France ceased to be the general bugbear, and new alliances began to be formed in order to check the aggressive spirit of Russia. The European Coalition, once dissolved, might not be so easily reconstituted. Internal politics also had altered. A wild party of ultras had sprung up among the royalists; the church was beginning to give disquiet to the holders of national property; the army was enraged by seeing *émigrés* who had fought against France appointed in great numbers to the command of regiments.

It was not the first time that Napoleon had gone into a sort of exile. As he had disappeared in the East, and returned to make Brumaire, so he might come from Elba to rescue France. The situation was not less intolerable than in 1799. As then, so now, had he not returned, a revolution would, nevertheless, have taken place. Fouché was weaving a military plot, which would have carried to power perhaps the duke of Orleans, perhaps the king of Rome.

The Hundred Days.

He entered upon the last of his thousand adventures on February 20, 1815, when he set sail from Porto Ferraio with Generals Bertrand and Drouot and 1100 soldiers. On March 1st he reached the French coast between Cannes and Antibes. Twenty days after he entered the Tuileries in triumph.

He had judged the feeling of the army correctly, and also the effect which would be produced by his prodigious fame. These causes were more than enough to overthrow a Government so totally without root as that of the Bourbons. From the coast he took the way across the mountains of Provence by Sisteron and Gap to Grenoble. The soldiers sent from this town to stop him were disarmed when he uncovered his breast and asked, Which of them would fire on his emperor? He was then joined by the royalist La Bédoyère. Macdonald at Lyons stood firm, but was deserted by his soldiers. Ney, who commanded in the east, at first declared himself violently against his old chief, but the military feeling afterwards gained him, and he joined Napoleon at Auxerre. The king left the Tuileries on the 19th, retiring northward, and on the next day Napoleon entered Paris.

At Brumaire he had put down Jacobinism, and given the nation order and repose. Now he was summoned, in the name of liberty, to protect the acquisitions of the Revolution and to defend the national honour against the triumphant foreigner. The Hundred Days are the period of popular or democratic imperialism. Those who sided with him told him frankly that he must turn over a new leaf, and he professed himself ready to do so. It would be rash to say that this was impossible. He was but forty-five; his return from Elba was an astonishing proof that he still possessed that elasticity of spirit, that power of grasping the future, which he had often shown so remarkably. Here then, as at a second Brumaire, might begin a third Napoleonic period. The mad crusade against England and the world-empire which sprang out of it were now to be forgotten; he was to stand out as a hero of national independence and of modern ideas together, a representative of the free modern people against the Holy Alliance. This last and most surprising of his transformations was already most prosperously begun. But at this point fortune deserted him once for all. Napoleon Liberator remained a poetical idea, transforming his past life into legend, and endowing French politics with a new illusion; the attempt to realize it came to an end in a hundred days (March 13 to June 22).

The ultimate cause of this failure seems to have been a change in Napoleon himself. It had long been remarked that the emperor Napoleon was wholly different from the general Bonaparte of the Italian campaigns. Bonaparte had been lean, shy, laconic, all fire and spirit, the very type of republican virtue imagined by Rousseau; the emperor was fat and talkative, and had his fits, according to Marmont, of indolent ease. Once or twice there had been attacks of illness, by which he had been temporarily incapacitated; but this had been hushed up. On the whole he had never yet been wanting to himself. In the campaign of 1814 his activity had been prodigious, and the march to Paris in twenty days, with which he had opened 1815, had been a great display of vigour. But he could not maintain himself at this level. A physical decay had begun in him, affecting through his body, not indeed his mind, but his will and his power of application. "I do not know him again," said Carnot. "He talks instead of acting, he the man of rapid decisions; he asks opinions, he the imperious dictator, who seemed insulted by advice; his mind wanders, though he used to have the power of attending to everything when and as he would; he is sleepy, and he used to be able to sleep and wake at pleasure." This last symptom was the most striking; in some of the most critical and terrible moments of the Waterloo campaign he seems to have been scarcely able to keep himself awake.

The constitutional history of the Hundred Days may be despatched summarily, since it led to nothing. On March 13 an imperial decree was issued from Lyons dissolving the two chambers established by the Bourbons, and convoking an extraordinary assembly in Field of May for the purpose "of correcting and modifying our constitutions and of assisting at the coronation of the empress, our dear and well-beloved spouse, and of our dear and well-beloved son." But the prospect soon changed, and, as it was necessary that the empire, like the monarchy, should have its charter, it seemed impossible to wait till May. Napoleon had recourse to Benjamin Constant, that is, he marked his change of policy by sending for the leader of the opposition. The "Acte Additionnel aux Constitutions de l'Empire," dated April 22, was drawn by Constant, examined by a committee, and then adopted by the council of state. The most remarkable feature of it is the preamble,

its eastern side, extending about a mile in length and ¾ of a mile in breadth. Immediately to the south, and connected with the mainland by a bridge, lies the half-artificial island of Desima (600 feet by 240), which, originally occupied by the Portuguese (1637–39), was for more than two hundred years (1641–1854) the trading post and prison-house of the Dutch traders. Southwards along the shore, on ground largely reclaimed from the sea, runs the foreign settlement, with the American, British, French, and Portuguese consulates on the hilly ground behind. The magnificent dock (460 feet long, 89 wide, and 28 deep), commenced by the prince of Hizen in 1865, and rebuilt in 1874–79, occupies a deep gorge between two hills at Tatagami, on the western side of the firth opposite the city; a few hundred yards to the north of the dock are the engine-works of Akaonura (with an area of 7 acres); and at Ko-ki there is a fine patent slip constructed for the prince of Satsuma (the prince of Hizen's rival). Nagasaki is laid out with great regularity and neatness, the streets crossing each other at right angles; beginning to climb the hills, they not infrequently end in stairs. Among the public buildings may be mentioned the hospital established in 1861, the oldest in Japan, and the great Government school, with its department for European languages and sciences, attended by hundreds of Japanese of all ages and ranks. Population about 80,000.

In 1825 the trade of the Dutch monopolists, who were allowed to have only two vessels, amounted to upwards of £100,000 (£31,151 imports and £72,373 exports). By 1871, twelve years after the opening of the port, this sum was multiplied more than sevenfold (£317,727 imports, £449,855 exports), and since then there has been a slight additional increase—£755,180 being the average of the four years 1878–81. The principal exports are coal (£228,000 in 1881), camphor, rice (now largely sent to Australia), tea, tobacco, dried fish, and vegetable wax. Most of the coal, which makes excellent coke, and is freely used by men-of-war and merchant steamers, is brought from the Takashima mines about 6 miles distant, which give employment to 4000 workmen. The export of camphor has steadily increased from 2380 piculs in 1877 to 11,640 piculs (worth £42,928) in 1881. Of the 333 vessels which entered the port in 1881, 280 were British. Nagasaki has regular steamship communication with Shanghai, and is the terminus of submarine telegraphs from that city and from Vladivostok.

NAGÍNA, a town in Bijnaur district, North-Western Provinces of India, is situated on the road from Hardwár to Muradábád, in 29° 27′ 5″ N. lat. and 78° 28′ 50″ E. long., with a population of 20,503 in 1881. The headquarters of the district were removed from it to Bijnaur town in 1824. It is celebrated for its ebony carvings. There are also manufactures of glassware, ropes, and matchlocks, and a large export of sugar.

NAGOYA, sometimes NOGOYA, one of the largest and most active of the cities of Japan, the chief town of Aichi *ken* (province of Owari), and formerly the seat of the princes of Owari (one of the "three august families" closely allied to the Tokugawa line of shoguns), lies at the head of the shallow Owari Bay, about 30 miles from Yokai-ichi, its port, with which it communicates by light-draught steamers. Nagoya is well known as one of the great seats of the pottery trade (though the master potters for the most part get their goods manufactured at Seto, about 13 miles distant, where the clay has been worked for wellnigh two thousand years); fans and enamels are also made in the city. The castle of Nagoya, occupying about 400 acres of ground at the north side of the city, erected in 1610, suffered comparatively little during the revolution of 1868, and is now the headquarters of the Nagoya military district, with extensive barracks and drill-grounds. The central keep of the citadel is a remarkable structure, covering close upon half an acre, but rapidly diminishing in each of its five stories till the top room is only about 12 yards square. Gabled roofs and hanging rafters break the almost pyramidal outline; and a pair of gold-plated dolphins 8 feet high form a striking finial. Both were removed in 1872, and one of them was at the Vienna Exhibition in 1873; but they have been restored to their proper site. Among the religious buildings perhaps the most interesting is the Kenchiu-ji, a monastery of the Jo-do sect, containing the burial-place of the princes of Owari. A superior court, a middle school, a girls' school, a normal school, the prefecture, the telegraph and post-office, and the hospital are the principal foreign-style buildings in Nagoya. The population is 325,000.

NÁGPUR, a district in the division of the same name, in the Central Provinces of India, lying between 20° 36′ and 21° 43′ N. lat., and between 78° 17′ and 79° 42′ E. long., bounded on the N. by Chhindwára and Seoni, E. by Bhandára, S. by Chánda and Wardhá, and W. by Wardhá and Ellichpur, with an area of 3786 square miles. Nágpur district lies immediately below the great table-land of the Sátpura range. A second line of hills shuts in the district on the south-west, and a third runs from north to south, parting the country into two plains of unequal size. These hills are all offshoots of the Sátpuras, and nowhere attain any great elevation. Their heights are rocky and sterile, but the valleys and lowlands at their feet are fertile, yielding rich crops of corn and garden produce. The western plain slopes down to the river Wardhá, is watered by the Jám and Madár rivers, tributaries of the Wardhá, and contains the most highly-tilled land in the district, abounding in fruit trees, and the richest garden cultivation. The eastern plain (six times the larger), stretching away to the confines of Bhandára and Chánda, consists of a rich undulating country, luxuriant with mango groves, and dotted towards the east with countless small tanks. It is watered by the Kanhán, with its tributaries, which flows into the Wainganga beyond the district.

The population in 1881 was 697,356 (British-born, 1063; other Europeans and Americans, 383; Eurasians, 630; aborigines, 42,750; Hindus, 606,223; Mohammedans, 39,765; Buddhists and Jains, 3589). The most numerous of the aboriginal tribes are the Gonds (13,885). The population of the nine principal towns was as follows:—Nágpur, 79,842; Kámthi, 36,381; Umrer, 12,784; Rámtek, 6978; Khápa, 6661; Narkher, 6498; Mohpa, 5256; Kalmeshwar, 4842; Saoner, 4739.

Of the area of 3786 square miles, 1863 were cultivated in 1882. Wheat in 1882 occupied 314,037 acres, rice 38,127, other food grains 489,111, oil-seeds 224,495, cotton 101,166, and sugar-cane 1545. During the last few years there has been a great increase in the manufacture of cotton in the Empress mills at Nágpur. There were 30,000 spindles in operation in 1882, the output of yarn and cloth being 1,804,530 and 149,995 ℔ respectively. The Nágpur branch of the Great Indian Peninsula Railway runs through the district for a distance of 26 miles. The gross revenue in 1876–77 was 1,460,168 rupees.

NÁGPUR, the chief town of Nágpur district, and the administrative headquarters of the Central Provinces, India, is situated in the centre of the district, on the banks of a small stream, the Nág, in 21° 9′ 30″ N. lat., 79° 7′ E. long. The population was 79,842 in 1881. The municipal limits include, besides the city proper, the suburb of Sítábaldí, and the European station of Sítábaldí, with Táklí. In the centre stands Sítábaldí Hill, crowned with the fort, which commands a fine view of the country round. On the north and west lies the prettily wooded station of Sítábaldí; beyond, to the north, are the military lines and *bázárs*, and, again, beyond these the suburb of Táklí. Close under the southern side of the hill is the native suburb of Sítábaldí. Below the eastern glacis of the fort is the railway terminus. Beyond this lies the broad sheet of water known as the Jamá Taláo, and farther east is the city, completely hidden in a mass of foliage. Three great roads connect the city with the European station. Handsome tanks and gardens, constructed by the Mahratta princes, lie outside the city. Many Hindu temples, elaborately carved in the best style of Mahratta archi-

of proprietors was 537, possessing lands of a gross annual value of £41,767. Of these 467 possessed less than 1 acre, and 5 more than 5000 acres, viz., earl of Cawdor, 46,176 acres; James C. G. Brodie, 22,378; N. J. M'Gillivray, 12,600; earl of Leven and Melville, 7805; and Hugh Davidson, 6363. There are several fine mansions in the county, in addition to a number of shooting lodges. The coast is skirted by the Highland Railway, and there is a good harbour at Nairn. The county possesses no special trade or manufacture, but there is a large distillery at a short distance from the county town.

Nairn includes three entire parishes, Ardclach, Auldearn, and Nairn, and portions of the parishes of Cawdor, Croy, Dyke, Moy, Petty, Daviot, and Urquhart,—the last two being detached portions, lying within Inverness and Ross respectively, at considerable distances from the rest of the county. Since 1801, when it was 8322, the population has been slowly but steadily increasing, and in 1881 numbered 10,455 (4979 males and 5476 females). There is one royal burgh, Nairn, and a burgh of barony, Auldearn. The county is under the same sheriffdom as Elgin and Banff, and unites with Elgin in returning a member to parliament. Anciently Nairn was included under the province of Moray, which was governed by a ri or mormaer. Roman coins have been found at a vitrified fort on the summit of a hill in the parish of Cawdor. There are numerous stone circles, including a very perfect one on the summit of Lethenbar Hill, one at Golford, and one at Moyness consisting of two concentric circles and a rocking stone. Cawdor Castle, a fine baronial structure, in a very picturesque situation, 5 miles south of Nairn, is associated in unauthentic legend with the murder of King Duncan by Macbeth; but no part of the building is really older than the 15th century.

NAIRN, a royal and parliamentary burgh and county town, is pleasantly situated near the Moray Firth, on the left bank of the Nairn, and on the Highland Railway, 93 miles west-north-west of Aberdeen and 15 north-east of Inverness. The principal buildings are the town and county hall (1818) surmounted by a spire, the hospital (1846) in the Italian style, the new public hall erected at a cost of £12,000, and the academy. Nairn is much frequented in summer for sea-bathing, and possesses very complete artificial baths. There is a commodious harbour with breakwater and pier. The principal exports are corn, eggs, potatoes, herrings, haddocks, freestone, and timber, and the principal imports coal, lime, and provisions. There are freestone quarries in the neighbourhood, and the town possesses rope and twine factories. There is also a salmon fishery. The burgh unites with Fortrose, Forres, and Inverness in returning a member to parliament. The population of the parliamentary burgh in 1881 was 4161, and that of the royal burgh 4665.

The town, whose original name was Invernairn, stood at first at some distance from its present site. Its earliest extant charter, which bears, however, to be a renewal of one received from Alexander I. in the 12th century, was granted by James VI. in 1589. At that time the inhabitants of the western half of the town spoke only Gaelic, and until a late period the distinction between the two sections of the town inhabited by different races was very clearly marked.

NAIRNE, CAROLINE OLIPHANT, BARONESS (1766–1845), the authoress of many fine Scotch songs, was born in the "auld hoose" of Gask, Perthshire, 16th August 1766. She was descended from an old family which had settled in Perthshire in the 13th century, and which could boast of kinship with the royal race of Scotland. Her father, Laurence Oliphant, was one of the foremost supporters of the Jacobite cause, and she was named Caroline in memory of Prince Charlie. In early childhood her health was extremely delicate, but a certain refined sensibility was the only trace of this which she retained in after years. In the schoolroom she was known as "pretty Miss Car," and afterwards her striking beauty and pleasing manners earned for her the name of the "Flower of Strathearn." Miss Oliphant was one of the earliest admirers of Robert Burns, and induced her brother Laurence to enter his name as subscriber to the first edition of his poems. It was the attempts of Burns in the *Scots Musical Museum* to adapt words of a more refined character to the old Scotch airs that suggested to her to undertake a similar enterprise. Her first effort was a new version of the "Pleughman," which her brother introduced at an entertainment to the Gask tenantry, and which soon met with great popularity throughout central Scotland. In June 1800 she married William Murray Nairne, whose rank as fifth Lord Nairne was in abeyance on account of attainder. He was then assistant inspector-general of barracks in Scotland. At the instigation of the Misses Hume, daughters of Baron Hume, she some time after her marriage undertook to bring out a collection of national airs set to appropriate words. To the collection she contributed a large number of original songs, adopting the signature "B.B."—"Mrs Bogan of Bogan." The music was edited by R. A. Smith, and the collection was published at Edinburgh under the name of the *Scottish Minstrel* (6 vols., 1821–24). Her husband was restored to his rank in 1824, but died 9th July 1830. After his death she took up her residence at Enniskerry, county Wicklow, but on account of the delicate health of her only son she went to the Continent, where she spent several years. The son died at Brussels in 1838. Lady Nairne returned to Gask in 1843, and died there 26th October 1845.

The songs of Lady Nairne may be classed under three heads:—(1) those illustrative of the characters and manners of the old Scotch gentry, such as "The Laird of Cockpen," "The Fife Laird," and "John Tod"; (2) Jacobite songs, composed for the most part to gratify her kinsman the aged chief of Strowan, among the best-known of which are perhaps "Wha'll be King but Charlie," "Charlie is my Darling," "The Hundred Pipers," "He's owre the Hills," and "Bonnie Charlie's noo awa"; and (3) songs not included under the above heads, ranging over a variety of subjects from "Caller Herrin'" to the "Land o' the Leal." For vivacity, genuine pathos, and bright wit her songs are surpassed only by those of Burns, and, although their note is less full and strong than his, it is perhaps in some respects more mellow and tender.

Lays from Strathearn, by Caroline, Baroness Nairne, arranged with Symphonies and Accompaniments for the Pianoforte by Finlay Dun, appeared without date some time after her death. Her poems were published in vol. i. of the *Modern Scottish Minstrel*, 1857; but the most complete collection is that contained in *Life and Songs of the Baroness Nairne, with a Memoir and Poems of Caroline Oliphant the Younger*, edited by Rev. Charles Rogers, LL.D., 2d ed., 1869.

NAKHICHEVAN, or NAKHJEVAN, a city of Russian Armenia, the chief town of a circle in the government of Erivan, is situated in 39° 12′ N. lat. and 45° 25′ E. long., 100 miles south-east of Erivan and 267 miles from Tiflis. It occupies the brow of one of the last spurs of the Karabakh Mountains (Anti-Caucasus), 3015 feet above the sea, and looks out over the wide and beautiful valley of the Araxes. Built and rebuilt again and again, Nakhichevan is full of half-obliterated evidence of former periods of prosperity. The present houses have for the most part been quarried from ancient ruins; of the palace of the Atabeks of Azerbijan there still remains a gateway with a Persian inscription, flanked by two brick towers; and at a little distance stands the so-called Tower of the Khans, a richly decorated twelve-sided structure about 102 feet in circumference and 75 feet in height, dating, to judge by the marvellously executed inscription which runs round the cornice, from the 12th century. There are also ruins of a large mosque. Situated on the highroad to Tabriz and Teheran, Nakhichevan is the seat of a considerable transit trade. In the Persian period the city is said to have had 40,000 inhabitants; in 1863 there were only 6251, and in 1873 6877 (2157 Armenians, 4697 Tartars). At the latter date there were 1200 houses, one Russian Greek church, three Armenian churches, four mosques, and two caravanserais.

The origin of Nakhichevan (the Naxuana of Ptolemy) is unknown. Armenian tradition claims Noah as its founder, and a mean mound of earth in the city is still visited by many pilgrims as his grave. Laid waste by the Persians in the 4th century, Nakhichevan sank into comparative insignificance, but by the 10th century had recovered its prosperity. In 1064 it was taken by Alp Arslan, and in the 13th century it fell a prey to the followers of Jenghiz Khan. It afterwards suffered frequently during the wars between the Persians, Armenians, and Turks, and it finally passed into Russian possession by the peace of Turkmen-Chai in 1828.

smith's hearth, hammered on a low anvil, the nail length cut off on a chisel attached to the anvil, and the head formed by dropping the spike into a hole in a "bolster" of steel, from which enough of the spike is left projecting to form the head, which is variously flattened out. The head, in the case of clasp nails, is formed with two strokes of the hammer, while rose nails require four blows. The heads of the larger-sized nails are made with the aid of an "oliver" or mechanical hammer, and for ornamental or stamped heads "swages" or dies are employed. The conditions of life and labour among the hand nailers in England are exceedingly unsatisfactory: married women and young children of both sexes are set to work long hours in small filthy sheds attached to their dwellings, and their employment is controlled by middlemen or nail-masters, who supply them with the nail-rods and pay for work done, sometimes in money and sometimes in kind on the truck system. The handicraft is, however, an expiring industry, as machine-wrought and cut nails are rapidly supplanting most corresponding kinds of hand-made nails. Horse nails alone continue to be made in large measure by hand labour (at St Ninians near Stirling, as well as in the Birmingham district). These are made from the finest Swedish charcoal iron, hammered out to a fine sharp point. They must be tough and homogeneous throughout, so that there may be no danger of their breaking over and leaving portions sunk in the hoof. The credit of perfecting machinery for the making of nails belongs to American inventors, and by numerous stages the nail-making machines have arrived at a high degree of efficiency. Of late years mild steel, such as the plates employed for shipbuilding, has been largely used for machine-made nails. Without much detail it would be impossible to convey an idea of how the machine, fed with heated (to black heat only) strips of metal having a breadth and thickness sufficient for the nail to be made, shears off by means of its slicer the "nail blank," which, falling down, is firmly clutched at the neck till a heading die moving with sufficient force strikes against its upper end and forms the head, and the nail now completed is liberated, passing out through an inclined shoot. In the case of large nails the taper of the shank and point is secured by the sectional form to which the strips are rolled; brads, sprigs, and small nails, on the other hand, are cut from uniform strips in an angular direction from head to point, the strip being turned over after each blank is cut so that the points and heads are taken from opposite sides alternately, and a uniform taper on two opposite sides of the nail, from head to point, is secured. The machines turn out nails with wonderful rapidity, varying with the size of the nails produced from about 100 to 1000 per minute. Wire or French nails are made from round wire, which is unwound, straightened, cut into lengths, and headed by a machine the same in principle as the pin-making apparatus (see PINS), but the pointing is accomplished by the pressure of dies in the same manner as the head is formed. Cast nails, which are cast in sand moulds by the ordinary process, are used principally for horticultural purposes, and the hob-nails or tackets of shoemakers are also cast.

NAIN, LE. The three brothers Le Nain, who have of late attracted much attention, occupy a peculiar position in the history of French art. Although they figure amongst the original members of the French Academy, their works show no trace of the influences which prevailed when that body was founded. Their sober execution and choice of colour recall characteristics of the Spanish school, and when the world of Paris was busy with mythological allegories, and the "heroic deeds" of the king, the three Le Nain devoted themselves chiefly to subjects of humble life such as Boys Playing Cards, The Forge, or The Peasants' Noonday Meal. These three paintings, together with others, amongst which is the noble Procession in the Interior of a Church (erroneously attributed to the Le Nain), are now in the Louvre; various others may be found in local collections, and some fine drawings may be seen in the British Museum and in the Albertina; but their signature is rare, and is never accompanied by initials which might enable us to distinguish the work of one or other of the brothers. Their lives are lost in obscurity; all that can be affirmed is that they were born at Laon in Picardy early in the 17th century. In 1633 Antoine, the eldest, was admitted painter at Paris; in 1648 he and his brothers Louis and Mathew were received into the Academy, and in the same year both Antoine and Louis died. Mathew lived on till 1677; he bore the title of chevalier, and painted many portraits. Mary of Medici and Mazarin were amongst his sitters, but these works (like his portrait of the unfortunate Cinq Mars, sold by auction at the Palais Royal in 1848) seem to have disappeared. Champfleury has written two works on the brothers Le Nain (1850, 1865).

NAIRN, a small maritime county in the north-east of Scotland, is bounded W. and S. by Inverness, E. by Elgin, and N. by the Moray Firth. Its greatest length from north to south is about 20 miles, and its greatest breadth about 15 miles; the area is 114,400 acres, or about 179 square miles.

The coast is low and sandy, and is skirted by sandbanks which render navigation dangerous. The eastern part of the seaboard district is formed of low sand-hills which extend into Morayshire. Parallel with the coast-line there is a great deposit of sand and gravel, which forms a terraced bank rising to the height of about 90 feet, and extends from 4 to 5 miles inward; it rests on Old Red Sandstone, which sometimes protrudes on the surface. This undulating plain is bordered by a hilly region which occupies two-thirds of the county. Where it joins the plain it is skirted by a strip of Devonian associated with coarse conglomerate. The hills, some of which reach a height of about 1500 feet, are formed of granite and grey gneiss, with occasional beds of primitive limestone. Freestone is plentiful, and there is also a species of dark bluestone which is greatly valued for ornamental building. Shell-marl is obtained from several of the lochs. The only rivers are the Nairn and Findhorn, with their tributaries. The Nairn, after entering the county, flows north-east for a distance of about 30 miles, and falls into the Moray Firth at the town of Nairn. The Findhorn, which also rises in Inverness, flows north-east through the southern and hilly district of the county into Morayshire. The soil of the alluvial plain on the coast is light and porous, and has been rendered very fertile by careful cultivation. There is also some rich land on the Findhorn. The most advanced methods of agriculture are in operation, but only a small proportion of the surface is capable of tillage, scarcely more than a fifth of the total area being under crops. The hills are for the most part covered with heath or pasture suitable for sheep, intermixed with fir and larch plantations.

The number of holdings in 1880 was only 392, and of these 214 did not exceed 50 acres in extent, 92 were between 50 and 100 acres, and 86 above 100 acres. According to the agricultural returns of 1882 there were 26,463 acres under cultivation, of which 9359 were under corn crops, 4871 under green crops, 10,031 under rotation grasses, and 2124 permanent pasture; 12 acres were under orchards, and 13,241 under woods. Very little wheat is grown, the principal corn crops being barley or bere, 3156 acres, and oats, 5917 acres. Of the green crops 4201 acres were under turnips or swedes, and 617 under potatoes. Horses in 1882 numbered 1292, cattle 5992 (1801 being cows or heifers in milk or in calf), sheep 17,442, and pigs 981.

The valued rental of the county in 1674 was £15,162 Scots, or about £1263 sterling. Exclusive of railways, the valuation in 1881–82 was £36,217. According to the latest return the number

(Celtic, Roman, and English in Great Britain) who have set in the form of names the seal of their possession on the soil. Again, the meanings of the names illustrate the characters of the various races. The Romans have left us names connected with camps (castra, chesters) and military roads; the English have used simple descriptions of the baldest kind, or have exhibited their attachment to the idea of property; the Celtic names (like those which the red men have left in America, or the blacks in Australia) are musical with poetic fancy, and filled with interest in the aspects and the sentiment of nature. Our race carries with it the ancient names of an older people into every continent, and titles perhaps originally given to places in the British Isles by men who had not yet learned to polish their weapons of flint may now be found in Australia, America, Africa, and the islands of the furthest seas.

Local names were originally imposed in a handy local manner. The settler or the group of cave-men styled the neighbouring river "the water," the neighbouring hill "the peak," and these terms often still survive in relics of tongues which can only be construed by the learned. The history of personal names is longer and more complex, but proceeds from beginnings almost as simple. But in personal names the complexity of human character, and the gradual processes of tangling and disentangling the threads of varied human interest, soon come in, and personal names are not imposed once and for all. Each man in very early societies may have many names, in different characters and at different periods of his life. The oldest personal names which we need examine here are the names which indicate, not an individual, but a group, held together by the conscious sense or less conscious sentiment of kindred, or banded together for reasons of convenience. An examination of customs prevalent among the most widely separated races of Asia, Africa, Australia, and America proves that groups conceiving themselves to be originally of the same kin are generally styled by the name of some animal or other object (animate or inanimate) from which they claim descent. This object is known as the "totem," from the Red-Indian word *dodhaim*. Of this topic it must here suffice to say that the earliest and most widely spread class and family names among uncivilized people are totemistic. The groups of supposed kin, however widely scattered in local distribution, are known as wolves, bears, turtles, suns, moons, cockatoos, reeds, and what not, according as each group claims descent from this or that stock, and wears a badge representing this or that animal, plant, or natural object. Unmistakable traces of the same habit of naming exist among Semitic and Teutonic races, and even among Greeks and Romans. The origin of this class of names cannot well be investigated in this place, but it may be observed that the names chosen are commonly those of objects which can be easily drawn in a rude yet recognizable way, and easily expressed in the language of gesture. In addition to the totem names (which indicate, in each example, supposed blood-kindred), *local* aggregates of men received local names. We hear of the "hill-men," "the cave-men," "the bush-men," "the coast-men," the "men of the plain," precisely as in the old Attic divisions of Aktaioi, Pediaioi, and so forth. When a tribe comes to recognize its own unity, as a rule it calls itself by some term meaning simply "the men," all other tribes being regarded as barbarous or inferior. Probably other neighbouring tribes also call themselves "the men" in another dialect or language, while the people in the neighbourhood are known by an opprobrious epithet, as *Rakshasas* among the early Aryan dwellers in India, or *Eskimo* (raw-eaters) in the far north of the American continent.

Leaving tribal for personal names, we find that, among most uncivilized races, a name (derived from some incident or natural object) is given at the time of birth by the parents of each new-born infant. Occasionally the name is imposed before the child is born, and the proud parents call themselves father and mother of such an one before the expected infant sees the light. In most cases the name (the earliest name) denotes some phenomenon of nature; thus Dobrizhofer met in the forests a young man styled "Gold flower of day," that is, "Dawn," his father having been named "Sun." Similar names are commonly given by the natives of Australia, while no names are more common among North-American Indians than those derived from sun, moon, cloud, and wind. This simple historical fact is very damaging to the mythological theories which resolve into solar or elemental myths all legends where the names of the characters can be philologically twisted into descriptions of natural phenomena. It is concluded that these myths originally described incidents in the life of clouds, winds, and tides, whereas names like those on which the theory depends are commonly applied by savage peoples to ordinary human beings. Marshal Saxe was not the sun because his mistress was named "Aurore," and Cephalus and Procris were real persons to those who heard their story, although by a series of logical jumps their names may be interpreted as synonyms of the sun and the dew.

The names of savage persons are not permanent. The name first given is ordinarily changed (at the ceremony answering to confirmation in church) for some more appropriate and descriptive nickname, and that, again, is apt to be superseded by various "honour-giving names" derived from various exploits. The common superstition against being "named" has probably produced the custom by which each individual is addressed, when possible, by some wide term of kinship—"brother," "father," and the like. The bad luck which in Zulu customs as in Vedic myths attends the utterance of the real name is evaded by this system of addresses. Could we get a savage—an Iroquois, for example—to explain his titles, we would find that he is, say, "Morning Cloud" (by birth-name), "Hungry Wolf" (by confirmation name), "He that raises the white fellow's scalp" (by honour-giving name), of the Crane totem (by family and hereditary name, as understood by ourselves). When society grows so permanent that male kinship and paternity are recognized, the custom of patronymics is introduced. The totem name gives place to a gentile name, itself probably a patronymic in form; or, as in Greece, the gentile name gives place to a local name, derived from the deme. Thus a Roman is called Caius; Julius is his gentile name (of the Julian clan); Cæsar is a kind of hereditary nickname. A Greek is Thucydides (the name usually derived from the grandfather), the son of Olorus, of the deme of Halimusia.

This system of names answered the purposes of Greek and Roman civilization. In Europe, among the Teutonic races, the stock-names (probably totemistic in origin) survive in English local names, which speak of the "ton" or "ham" of the Billings or Tootings. An examination of these names, as collected in Kemble's *Anglo-Saxons*, proves that they were originally derived, as a rule, from animals and plants. Our English ancestors had for personal names compound words, as "Noble Wolf" (Ethelwulf), "Wolf of War," and so forth, and these names certainly testify to a somewhat primitive and fierce stage of society. Then came more vulgar nicknames and personal descriptions, as "Long," "Brown," "White," and so forth. Other names are directly derived from the occupation or craft (Smith, Fowler, Sadler) of the man to whom they were given, and yet other names were derived from places. The noble and

NAKHICHEVAN-ON-THE-DON, a town of southern Russia, situated in the government of Ekaterinoslaff, district of Rostoff, 6 miles by rail to the north-east of the latter town, on the right bank of the Don. It was founded in 1780 by Armenians who emigrated from the Crimea and were allowed to settle on the banks of the Don, forming there an independent district between Azoff and the fort of St Demetrius, now Rostoff; they gave to the chief town of their new settlement the name of the older city in Caucasus. Owing to the fertility of the region, its advantageous situation for trade, and the privileges granted to the settlers, Nakhichevan soon became a wealthy place, and it still is the administrative centre of the "Armenian district," which extends as a narrow strip along the banks of the Don, with a population of upwards of 25,000, of whom 16,500—principally Armenians, with some 2000 Russians—are settled at Nakhichevan. The town has several tobacco and wadding factories, tallow-melting houses, soap-works, brick-works, and tanneries, with an aggregate annual production of about £100,000. The chief occupation of the Armenians, however, is trade, which they carry on throughout southern Russia, while the less wealthy of them are renowned as innkeepers on the Caucasus. The rural population depend mainly on cattle-breeding, and to some extent also on fishing.

NAMAQUALAND, a vast region of south-western Africa, extending along the west coast for a distance of 600 miles from the south of Damaraland (22° 43′ S. lat.) to the north of the county of Clanwilliam (30° 35′ S. lat.), and stretching inland from 80 to 350 miles. It is divided by the lower course of the Orange River into two portions —Little Namaqualand to the south, and Great Namaqualand to the north. Little Namaqualand, incorporated with Cape Colony since 1865, has an area of 20,635 square miles, and in 1875 had a population of 12,233, of whom 2675 were whites. The seat of magistracy is at Springbokfontein, on a branch of the Buffels River, about 60 miles from the coast, with which it communicates by a mule-railway (96 miles long) ending at Port Nolloth on Robbe or Seal Bay. Ookiep, 6 miles to the north of Springbokfontein, is, next to the diamond fields of Kimberley, the most important mining place in South Africa, its copper mines (worked by the Cape Copper Mining Company) giving employment to about 1500 people; the output in 1882 was 16,311 tons of extremely rich ore. The European miners are mainly from Cornwall and Mansfeld. Copper is also worked at Concordia, Spektakel, and (since 1853) Kodas. Great Namaqualand has an area of 987,000 square miles, about sixteen times the size of England; but its population does not exceed 20,000, mostly Namaquas and other Hottentots (see Hottentots). For 30, 40, or even 100 miles inland the country is a sandy waste, and on the eastern side it passes off into the great Kalahari desert. The central portion is traversed from north to south by the Fish River or Oub and its tributaries, which ultimately reach the Orange River about 70 miles above its mouth; but, except after rain, they are mere dry beds. And the rains are periodical and partial,—the result almost always of thunderstorms. In a few minutes after the thunder-clouds have burst the country is flooded; turbid currents half a mile wide roar through a ravine which has not shown a drop of water for years previously; rivulets flow where one would think water had never run before (J. F. Wilson). The surface of the interior part of the country is covered with hills, irregularly distributed, but with a general tendency to run in lines parallel to the coast. Towards the south-east the Gei Kharas mountains reach a height of 6570 feet, and the smaller Khari Kharas group about 5200. The Nuaibeb mountains on the borders of Damaraland are a little higher (6700 feet). The only Europeans as yet settled in Great Namaqualand are the Basel and the Wesleyan missionaries; but it has been decided to establish a regular German colony at Angra Pequeña, the only important bay on the whole coast. The country, like Little Namaqualand, has long been known to be rich in minerals. The proposal made about 1876 to annex it and Damaraland to Cape Colony fell through.

Benjamin Ridsdale, *Scenes and Adventures in Great Namaqualand*, 1883.

NAMES. Names, and the study of proper names of persons and places, are not without scientific and historical importance, but, on the whole, are perhaps rather matter of curious interest. It stands to reason that, even in the earliest societies of "articulate speaking men," all known persons, places, and groups of human beings must have had names by which they could be spoken of and by which they were recognized. The study of these names and of their survival in civilization enables us in some cases to ascertain what peoples inhabited districts now tenanted by persons of far different speech. Thus the names of mountains and rivers in many parts of England are Celtic, —for example, to take familiar instances, Usk, Esk, and Avon. There are also local names (such as Mona, Monmouth, Mynwy, and others) which seem to be relics of tribes even older than the Celtic stocks, and "vestiges of non-Aryan people, whom the Celts found in possession both on the Continent and in the British Isles."[1] These are affairs of somewhat dubious conjecture, but it is certain enough that the Celtic names, with their mysterious and romantic sounds, do linger in English valleys like the last echoes of Arthur's horn among the hollows of the hills. And it is no less certain that the English name is sometimes the mere translation, perhaps unconscious, of the earlier Celtic appellation, often added to the more ancient word. Penpole Point in Somerset is an obvious example of this redoubling of names. As to the meaning and nature of ancient local names, they are as a rule purely descriptive. A river is called by some word which merely signifies "the water"; a hill has a name which means no more than "the point," "the peak," "the castle." Celtic names are often of a more romantic tone, as Ardnamurchan, "the promontory by the great ocean," an admirable description of the bold and steep headland which breasts the wash of the Atlantic. As a general rule the surviving Celtic names, chiefly in Ireland, Wales, and Scotland, all contain some wide meaning of poetic appropriateness. The English names, on the other hand, commonly state some very simple fact, and very frequently do no more than denote property, such and such a town or hamlet, "ton" or "ham," is the property of the Billings, Uffings, Tootings, or whoever the early English settlers in the district may have been. The same attachment to the idea of property is exhibited in even the local names of petty fields in English parishes. Occasionally one finds a bit of half humorous description, as when a sour, starved, and weedy plot is named "starvacre"; but more usually fields are known as "Thompson's great field," "Smith's small field," "the fouracre," or the like. The name of some farmer or peasant owner or squatter of ancient date survives for centuries, attached to what was once his property. Thus the science of local names has a double historical value. The names indicate the various races

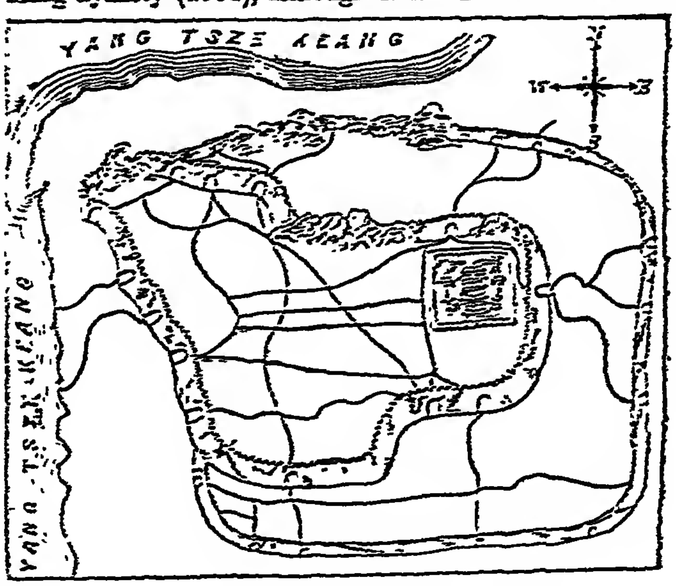
and the canal from the Marne to the Rhine. Other railways—to Metz, to Épinal by Mirecourt, to Château Salins—join the main line in the neighbourhood, and make the place an important junction. The Place Stanislas is worthy of a capital city: in the centre stands the statue of Stanislas Leczinski, ruler of Lorraine (who still remains the most popular personage in the town which he embellished), and on all sides rise imposing buildings in the 17th-century style—the town-hall, episcopal palace, theatre, &c. The streets opening into the square have railings of artistic workmanship. A fine triumphal arch known as the King's Gate leads from the Place Stanislas to the Place Carrière, which forms a beautiful tree-planted promenade, and at its further end contains the Government palace and the so-called Pépinière (nursery), with fine clumps of trees, grass, and flowers. Other open spaces in the city are the Place d'Alliance (formed by Stanislas, with a fountain in memory of the alliance between Louis XV. and Maria Theresa in 1756), the Place de l'Académie, the Cours Léopold, the Place St Epvre, the Place Dombasle, and the Place de la Gare. The town-hall contains a picture gallery. The cathedral, built in the 18th century, has a wide façade flanked by two dome-surmounted towers, and a somewhat frigid and sombre interior. Of particular interest is the church of the Franciscans (Cordeliers), in the old town, built by René II. to commemorate his victory over Charles the Bold in 1476. Pillaged during the Revolution period, but restored to religious uses in 1825, it contains the tombs of Antony of Lorraine and his wife Marie d'Harcourt, Philippe of Gueldres, second wife of René II., the engraver Jacques Callot, Henry III., count of Vaudémont, and Isabella of Lorraine his wife, René II. (a curious monument raised by his widow in 1515), and Cardinal de Vaudémont. Here also is a chapel built in the beginning of the 17th century to receive the tombs of the princes of the house of Lorraine. The church of St Epvre, rebuilt between 1864 and 1874 on the site of an old church in the style of the 13th, 14th, and 15th centuries, has a fine spire and belfry and good stained glass windows. Bonsecours Church, at the end of the St Pierre Faubourg, contains the mausoleums of Stanislas (by whom it was built) and his wife Catharine, and the heart of their daughter Marie, queen of France. Of the old ducal palace, begun in the 15th century by Duke Raoul and completed by René II., there remains but a single wing, and of this a portion was destroyed by a great fire in 1871, and has been replaced by an upper primary school built in the same 15th-century style as the rest of the building. The entrance to this wing is a delightful specimen of the late Gothic of the beginning of the 16th century. From the ground-floor gallery a fine staircase ascends to the Galerie des Cerfs, which accommodates the archæological museum of Lorraine; one of the greatest treasures of the collection is a piece of tapestry 92 feet long and 13 feet broad, which was found in the tent of Charles the Bold after the battle of Nancy. At a short distance from the railway station a cross marks the spot where the duke's body was found. Of the old gates of Nancy the most remarkable is the Porte de la Craffe.

Nancy is the seat of a bishop and of a court of appeal, and the headquarters of a military division dependent on the Châlons corps d'armée. It is also a university town, with the four faculties of medicine, literature, science, and law, and as an educational centre has risen in importance since 1871. It possesses a large library, archives of antiquarian interest, a botanical garden, and a museum of natural history, an academy, a geographical society, and an important school of forestry (see vol. ix. p. 403). The first agricultural station founded in France (1822) is at Roville in the vicinity. Timber, grain, and hops (largely grown in the district), rags for the paper-mills of the Vosges, and the embroidery which was its earliest industry have long been the objects of an extensive trade at Nancy; during the last fifty years the commercial and industrial importance of the place has been greatly increased by the construction of the railway and the canal from the Marne to the Rhine, now supplemented by the new eastern canal between the Meuse, the Moselle, and the Saône; and since the Franco-German war the manufacturing class has been recruited by numerous immigrants from Alsace. Round about the city are now to be seen the chimneys of iron-works and foundries, cotton-mills, chemical-works, and glass-works; and large numbers of the inhabitants are also employed in making straw-hats, artificial flowers, boots and shoes, and hosiery. A printing and publishing establishment of some importance has been transferred from Strasburg. The population was about 28,000 in the close of the 18th century, 43,000 in 1856, 52,000 in 1871, and 66,009 (73,225 as a commune) in 1881.

At the close of the 11th century Odelric of Nancy, brother of Gerard of Alsace, possessed at Nancy a castle which enabled him to defy the united assaults of the bishops of Metz and Treves and the count of Bar. In the course of the next century the town was surrounded with walls, and became the capital of the dukes of Lorraine; but its real importance dates from the 15th century, when (in 1477) Charles the Bold and his schemes of conquest perished at its gates. Enlarged, embellished, and admirably refortified by Charles III., it was taken by the French in 1633 (Louis XIII. and Richelieu being personally present at the siege); and when in 1661 it was restored by Louis XIV. Charles was compelled to raze its fortifications. After the peace of Ryswick in 1697 Duke Leopold, at length in quiet possession of his duchy, set himself to repair the disasters of the past. He founded academies, established manufactures, and set about the construction of the new town. But it was reserved for Stanislas Leczynski, to whom Lorraine and Bar were assigned in 1735, to carry out the plans of improvement and embellishment in a style which made Nancy one of the palatial cities of Europe, and rendered himself the most popular as he was the last of the dukes of Lorraine. The city, which became French in 1766, was occupied by the allies in 1814 and 1815, and put to ransom by the Prussians in 1870.

NANKING, or "the southern capital," is the name by which Keang-ning, the chief city in the province of Keang-soo, in China, has been popularly known for several centuries. The present city, which stands in 32° 5′ N. lat. and 118° 47′ E. long., dates only from the beginning of the Ming dynasty (1368), although it is built on the site of



Plan of Nanking.

one which for more than two thousand years has figured under various names in the history of the empire. The more ancient city was originally known as Kin-ling; under the Han dynasty (206 B.C. to 25 A.D.) its name was converted into Tan-yang; by the Tang emperors (618–907

landowner was called "of" such and such a place (the German *von*, and French *de*), while the humbler man was called not "of" but "at" such a place, as in the name "Attewell," or merely by the local name without the particle. If we add to these patronymics formed by the addition of "son," and terms derived from Biblical characters (the latter adopted after the Reformation as a reaction against the names of saints in the calendar), we have almost exhausted the sources of modern English and European names. A continual development of custom can be traced, and the analysis of any man's family and Christian names will lead us beyond history into the manners of races devoid of literary records. (A. L.)

NAMUR, a province of Belgium, is bounded on the N. by South Brabant, on the E. by Liége and Luxemburg, on the S. by France, and on the W. by Hainault, having a maximum length from north to south of 55 miles; its greatest breadth is 45 miles, and the area 1413 square miles. The surface is much varied by hill and dale, being traversed by the forest of Ardennes, which here attains a height of about 2100 feet; in some parts, especially in the valley of the Meuse between Dinant and Liége, the scenery is beautiful and romantic. The principal rivers are the Meuse and its tributary the Sambre, which joins it at Namur. Geologically the province belongs to the Carboniferous system; the iron mines are very rich, and along with the coal-pits employ a considerable proportion of the industry of the province. Lead mines are also worked to some extent; and building-stone, slate, and excellent marble are quarried. The soil in the arrondissement of Namnr is a rich marl, fertile and well-cultivated; about one-third of the entire province is occupied by wood, and in the arrondissement of Dinant there are considerable stretches of heath. The climate is, generally speaking, moist and cold. Wheat, rye, oats, barley, hemp, flax, and hops are the principal crops raised, but the vine is also grown. As regards live stock, sheep are preferred to horned cattle; large numbers of horses, strong and of a good breed, are also reared. The special manufacture of Namur is cutlery, for which the province is famed. Among the other industries may be mentioned porcelain and glass-making, paper-making, cotton-spinning, and tanning. At the census of 1876 the population was 315,796. There are three arrondissements,—Dinant, Namur, and Philippeville.

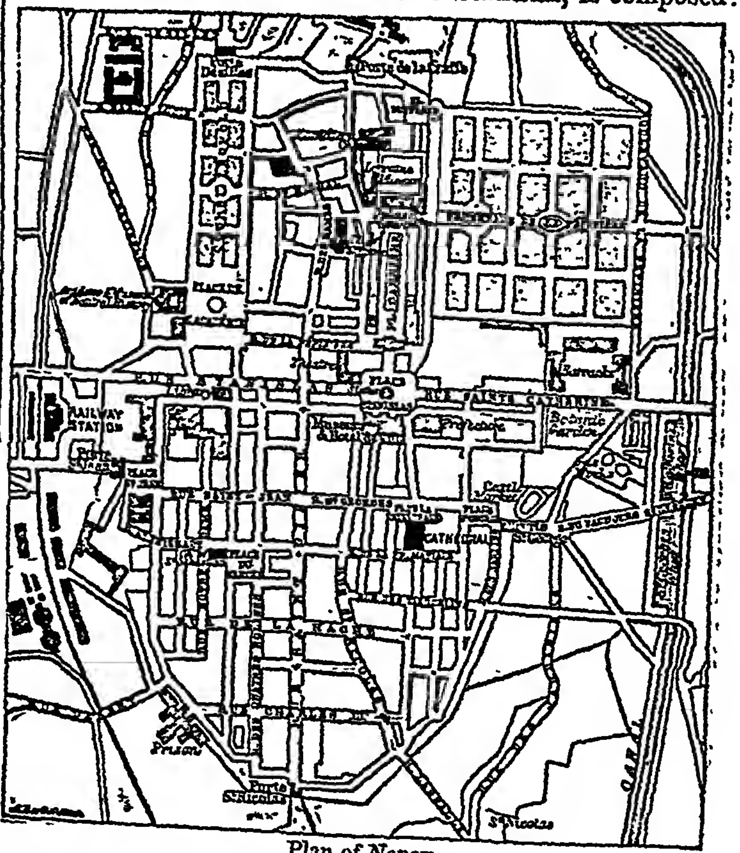
NAMUR (Flem., *Namen*), capital of the above province, is picturesquely situated on both banks of the Sambre, at the point of its junction with the Meuse, 35 miles south-east from Brussels. The rivers are crossed by several stone bridges. The streets are broad and clean, and there are two or three good squares. There are almost no buildings of any considerable antiquity now standing, if the 11th-century belfry and the palace of justice, dating from 1464 as the monastery of St Albinus, be excepted. The cathedral church of St Aubain or St Albin is a modern building (1751–72) in the Renaissance style, adorned in front with several statues in white marble. The interior has statues by Delvaux and Parmentier, a fine carved oak pulpit by Geerts, and the tomb of Don John of Austria, who died at his camp at Bouges, about a mile to the north-east of the town, in 1578. The church of St Loup is also a fine building, richly adorned in the interior with marble and stone carving. Besides several other churches, the town has a town-hall, a theatre, a seminary, a picture gallery, library, and archæological museum, various charitable institutions, barracks, &c. The manufactures are considerable, cutlery being the specialty. Tanning is also extensively carried on, and a great number of the inhabitants are employed in the mines and quarries of the neighbourhood. The situation of Namur gives it great advantages as a centre for trade. The population in 1875 was 27,068.

In Cæsar's time Namur was the capital of the Aduatuci, who, he tells us (*B. G.*, ii. 29), after his defeat of the Nervii, leaving all their other strongholds betook themselves to this one town "egregie natura munitum." Defended by walls of considerable thickness, by well-constructed outworks on both sides of the rivers, and by the citadel on a rocky eminence at their junction, it was long a place of great strength in modern times also. It was taken by Louis XIV. in 1692, an event which was recorded by Racine and celebrated in verse by Boileau, but it was recovered in 1695 by the British and Dutch under William III., after a siege of ten months. The fortifications were destroyed in 1784 by Joseph II. of Austria, restored and strengthened in 1817 under the inspection of Wellington, and finally razed in 1866.

NANAK. See INDIA, vol. xii. p. 808.

NANA SAHIB is the common designation of Dandhu Panth, adopted son of the ex-peshwa of the Mahrattas, Báji Ráo, who took a leading part in the great Indian mutiny, and was proclaimed peshwa by the mutineers. See INDIA, vol. xii. p. 810. Nana Sahib was responsible for the massacres at Cawnpore, and was engaged in the protracted campaigns in Oudh. In the closing days of 1859, when the last remnants of the rebels disappeared over the Nepalese frontier, the Nana was among the fugitives. His death was reported some time afterwards, but his real fate remains obscure. Compare NEPAL.

NANCY, the ancient capital of Lorraine, afterwards the chief town of the French department of Meurthe, and since 1872 that of the department of Meurthe-et-Moselle, is situated 219 miles east of Paris by railway, on the left bank of the Meurthe, 6 miles above its junction with the Moselle. It consists of two distinct portions: the old town in the north-west, between the citadel and the streets and square which bear the name of Stanislas, is composed



Plan of Nancy.

of narrow and winding streets; the Stanislas town in the south-east has, on the other hand, wide straight streets which cross each other at right angles and allow views of the hills around the city. Beyond the gates (several of which are preserved on account of their antiquarian interest, and still indicate the line of the old civic boundaries) long suburbs stretch out into the country. The railway from Paris to Strasburg skirts the city on the south-west side, and to the east and north lie the Meurthe

dence of the dukes of Brittany it became a state prison (Cardinal de Retz, Fouquet, and the duchess of Berri were confined within its walls), and it is now occupied by the artillery headquarters. The chapel in which the marriage of Louis XII. with Anne of Brittany was celebrated was destroyed by an explosion in 1800. Nantes possesses a fine theatre, a court-house, a prefecture, and an exchange, which includes both the tribunal and the chamber of commerce. The town-hall possesses a curious casket in gold and enamel which once, it is said, contained the heart of Anne of Brittany. The public library is in the old corn-market, and the museum of painting and sculpture finds scanty accommodation in the old cloth-market. Apart from the beautiful collection presented to the town by the duke of Feltre, the catalogue includes 1000 pictures and 130 statues. An archæological museum has its quarters in the old church of the Convent of the Oratory, where Fouché, afterwards duke of Otranto, taught before the Revolution; part of the old mint is occupied by the school of science and arts; and not far off is the museum of natural history, comprising a complete collection of the minerals of the department. The botanic garden consists of a purely scientific portion and a landscape garden which forms one of the finest promenades of its kind. Between

the Loire and the Erdre run Cours St Pierre and Cours St André, adorned at the two ends of the line by statues of Anne of Brittany and Arthur III., Du Guesclin and Olivier de Clisson, and separated by the Place Louis XVI., with a statue of that monarch on a column 92 feet high. The Place Royale, the great meeting-place of the principal thoroughfares of the city, contains a monumental fountain in blue Rennes granite, with a white marble statue of the town of Nantes and bronze statues of the Loire and four of its affluents—the Sèvre, the Erdre, the Cher, and the Loir. A flight of steps at the west end of the town leads up from the quay to the colossal cast-iron statue of St Anne, whence a splendid view may be obtained over the valley of the Loire. Several old houses of the 15th and 16th centuries, the fish market, the railway station, and the Salorges (a vast granite building now used as a bonded warehouse) are all of interest. Besides two great hospitals —St Jacques on the left bank of the Loire, with 1600 beds, and the Hôtel-Dieu, recently rebuilt in Gloriette island, with 1200 beds—Nantes contains a deaf-mute institute, a secondary school of medicine and pharmacy, a hydrographic school, a drawing school, a branch establishment of the conservatoire at Paris, and a lyceum. It is the see of a bishop, and the headquarters of the 11th corps d'armée. As a seat of the sugar manufacture Nantes stands next to Paris and Marseilles. In city or suburbs there are vast establishments for the manufacture of iron, copper, and lead, shipbuilding yards, factories for agricultural and similar implements, oil-works, soap-works, a national tobacco factory employing 1800 hands, a stained-glass factory, manure works, and granite yards. Food-preserving is a rapidly growing industry in all the three departments of meat, fish, and vegetables (the last largely grown in the neighbourhood). Commercially Nantes does not occupy so high a position as formerly, being now only eleventh in the list of French ports, though its custom-house still ranks second in amount of receipts. It imports coal from England (duty free), wood from Scandinavia, colonial wares from the Antilles. Its shipowners, whose vessels are rather more numerous than those of Havre, keep possession of the greater part of the trade of the lower Loire and the coast fisheries. In 1875 they had 745 vessels, of 150,000 tons aggregate burden. The commercial movement of the port was 235,000 tons; and the value of the exports and imports amounted to £5,000,000. In 1880 the movement was upwards of 400,000 tons.

Previous to the Roman occupation, Nantes (Condivicenum) was the chief town of the Nannetes, and under the conquerors it became a great commercial and administrative centre. In the middle of the 3d century Christianity was introduced by St Clair. Clotaire I. got possession of the city in 560, and placed it under the government of St Felix the bishop, who executed enormous works to cause the Loire to flow under the walls of the castle. After being several times subdued by Charlemagne, Brittany revolted under his successors, and Nominoé, proclaimed king in 842, ordered the fortifications of Nantes to be razed because it had sided with Charles the Bald. The Normans held the town from 843 to 936. About this time began the rivalry between Nantes and Rennes. Pierre de Dreux, declared duke of Brittany by Philip Augustus, made Nantes his capital, surrounded it with fortifications, and defended it valiantly against John of England. During the Breton wars of succession Nantes took part first with Montfort, but afterwards with Charles of Blois, and did not open its gates to Montfort till his success was assured and his English allies had retired. In 1560 Francis II. granted Nantes a communal constitution. In the course of the 15th and 16th centuries the city suffered from several epidemics. Averse to Protestantism, it joined the League along with Mercœur, governor of Brittany, who helped to raise the country into an independent duchy; and it was not till 1598 that it opened its gates to Henry IV., who here signed on May 2d of that year the famous edict which until its revocation by Louis XIV. in 1685 was the charter of Huguenot liberties in France (see vol. ix. p. 564, 579, and vol. xii. p. 335–9). It was at Nantes that Count Chalais was punished for plotting against Richelieu, that Fouquet was arrested, and that the Cellamare conspirators were executed under the regent. Having warmly embraced the cause of the Revolution in 1789, the city was in 1793 treated with extremest rigour by Carrier, of *noyade* fame. Under the empire its foreign commerce was ruined. The duchess of Berri was arrested at Nantes in 1832 while trying to stir up La Vendée against Louis Philippe. Anne of Brittany, Charles Errard, founder of the French Academy at Rome, Generals Cambronne and Lamoricière, and Jules Verne were born in the city.

NANTEUIL, ROBERT (1623–1678), a crayonist, and one of the most eminent of French line engravers, was born about 1623, or, as other authorities state, in 1630, the son of a merchant of Rheims. Having received an excellent classical education, he studied engraving under his brother-in-law, Nicholas Regnesson; and, his crayon portraits having attracted attention, he was pensioned by Louis XIV., and appointed designer and engraver of the cabinet to that monarch. It was mainly due to his influence that the king granted the edict of 1660, dated from St Jean de Luz, by which engraving was pronounced free and distinct from the mechanical arts, and its practitioners were declared entitled to the privileges of other artists. The plates of Nanteuil, several of them approaching the scale of life, number about three hundred. In his early practice he imitated the technique of his predecessors, working with straight lines, strengthened, but not crossed, in the shadows, in the style of Claude Mellan, and in other

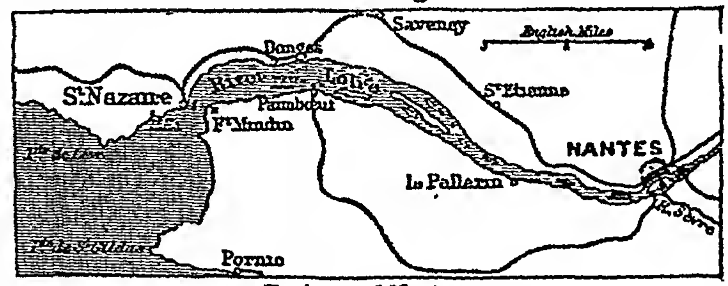
A.D.) it was styled Keang-nan and Shing Chow; by the first sovereign of the Ming dynasty (1368–1644 A.D.) it was created the "southern capital" (Nan-king), and was given the distinctive name of Ying-t'een; and since the accession to power of the present Manchu rulers it has been officially known as Keang-ning, though still popularly called Nan-king. As a matter of fact it was the seat of the imperial court only during the reigns of the first two emperors of the Ming dynasty, and was deserted for Shun-t'een (Peking) by Yung-lo, the third sovereign of that line, who in 1403 captured the town and usurped the crown of his nephew, the reigning emperor.

But even when speaking of the city rebuilt by the Ming emperors it is necessary to use the past tense. The Tai-ping rebels, who carried the town by assault in 1853, made a clean sweep of all the national monuments and most of the more conspicuous public buildings it contained, and destroyed or were the means of destroying the greater part of the magnificent wall which surrounded it. The following description, therefore, must be understood as referring to the town as it existed before it was invaded by those ruthless destroyers.

The city is said by Chinese topographers to have been surrounded by a wall measuring 96 le, or 32 miles, in circumference. This computation has, however, been shown by more accurate calculation to be a gross exaggeration, and it is probable that 60 le, or 20 miles, would be nearer the actual dimensions. The wall, of which only small portions now remain, was about 70 feet in height, measured 30 feet in thickness at the base, and was pierced by thirteen gates. Encircling the north, east, and south sides of the city proper was a second wall which enclosed about double the space of the inner enclosure. The public buildings were on a scale befitting one of the foremost cities in the empire, which was and still is the permanent seat of the provincial government, and which for a time was the abode of the imperial court. The inner city, which is nominally inhabited by the Manchu garrison only, is crossed from north to south by four main thoroughfares, which are intersected by roads connecting the gates in the eastern and western walls. In the north-east corner of the town stood the imperial palace reared by Hung-woo, the imperial founder of the modern city. After suffering mutilation at the time of the overthrow of the Ming dynasty, this magnificent building was finally burnt to the ground on the recapture of the city from the Taiping rebels in 1864. But beyond comparison the most conspicuous public building at Nanking was the famous porcelain tower, which was designed by the emperor Yung-lo (1403–28) to commemorate the virtues of his mother. Twelve centuries previously an Indian priest deposited on the spot where this monument afterwards stood a relic of Buddha, and raised over the sacred object a small pagoda of three stories in height. During the disturbed times which heralded the close of the Yuen dynasty (1368) this pagoda shared the fate of the surrounding buildings, and was utterly destroyed. It was doubtless out of respect to the relic which then perished that Yung-lo chose this site for the erection of his "token-of-gratitude" pagoda. At noon on the fifteenth day of the sixth month of the tenth year of the reign of this monarch (1413) the building was begun. But before it was finished Yung-lo had passed away, and it was reserved for his successor to see the final pinnacle fixed in its place, after nineteen years had been consumed in carrying out the designs of the imperial architect. In shape the pagoda was an octagon, and was about 260 feet in height, or, as the Chinese say, with that extraordinary love for inaccurate accuracy which is peculiar to them, 3½ chang (a chang equals about 120 inches) 9 feet 4 inches and $\frac{1}{10}$ of an inch. The outer walls were cased with bricks of the finest white porcelain, and each of the nine stories into which the building was divided was marked by overhanging eaves composed of green glazed tiles of the same material. The summit was crowned with a gilt ball fixed on the top of an iron rod, which in its turn was encircled by nine iron rings. Hung on chains which stretched from this apex to the eaves of the roof were five large pearls of good augury for the safety of the city. One was supposed to avert floods, another to prevent fires, a third to keep dust-storms at a distance, a fourth to allay tempests, and a fifth to guard the city against disturbances. From the eaves of the several stories there hung one hundred and fifty-two bells, and countless lanterns adorned the same coignes of vantage. The strange form and beauty of the edifice, which might have been expected to have preserved it from destruction, were, however, no arguments in its favour in the eyes of the Taiping rebels, who razed it to the ground when they made themselves masters of Nanking.

Nanking is about 194 geographical miles to the west of Shanghai, and is nearly equidistant between Canton and Peking. It is situated on the south bank of the Yang-tsze Keang, and has a population of 400,000 souls. In bygone days it was one of the chief literary centres of the empire, besides being famous for its manufacturing industries. Satin, crape, nankeen cloth, paper, pottery, and artificial flowers were among its chief products. Of late years, however, these peaceful industries have been superseded by the production of all kinds of warlike material. As at Fuh-chow, the arsenal at Nanking is superintended by Europeans, under whose guidance steam ships of war and cannon of the newest and most approved type are there manufactured. In the history of the political relations of England with China, Nanking principally figures as the city where, after its capture by British ships in 1842, Sir Henry Pottinger signed the "Nanking treaty." (R. K. D.)

NANTES, a city of France, chief town of the department of Loire-Inférieure, is situated on the right bank of the Loire, 35 miles above its mouth, in 47° 13′ N. lat. and 1° 33′ W. long. In population (117,555 inhabitants in 1881) it is the first city of Brittany. At Nantes the Loire receives on the left hand the Sèvre Nantaise, and on the right the Erdre, which forms the outlet of the canal between Nantes and Brest; and a large number of bridges spanning the various branches of the different streams join the several quarters of the city. Along the left bank of the Loire stretches an ever-extending line of factories and shipbuilding yards. In all there are 6 miles of quays, 2½ miles traversing the city in its greatest breadth from east to west along the main river. The



Environs of Nantes.

largest vessels at present come no farther than St Nazaire, but a canal is being made on the left bank which will allow vessels drawing 16 feet to come up to the city. Nantes lies 264 miles west-south-west of Paris by the Angers and Le Mans Railway, and 40 miles from St Nazaire. Other lines connect it with Rennes *via* Châteaubriant, La Roche-sur-Yon, Paimbœuf, and Pornic.

The cathedral of Nantes, commenced in 1434 in the Gothic style, is still unfinished. Its length will be, when completed 335 feet, and the nave is 85 feet wide and 123 feet in height The towers are 205 feet high. There are two interesting monuments in the transept,—on the right Michel Colomb's tomb of Francis II., duke of Brittany, and his second wife Marguerite de Foix (1507), and on the left that of General Lamoricière by Paul Dubois. The former consists of a white marble base covered by a black marble slab on which rest the two effigies, the four corners being occupied by upright figures of Justice, Fortitude, Temperance, and Prudence. Of the other churches the more interesting are St Nicolas, a modern building in the style of the 13th century, Ste Croix, which occupies the site of an old pagan temple, and St Jacques on the left bank of the Loire.

Between the cathedral and the Loire, from which it is separated only by the breadth of the quay, stands the castle of Nantes, founded in the 9th or 10th century. Re built by Francis II. and the duchess Anne, it was flanked by Mercœur in the time of the League with huge bastion decorated with the Lorraine cross. From being the resi

and may be separated by means of fractional distillation; together, under the name of caoutchine, they form a most efficient solvent for india-rubber itself. (6) *Bone naphtha*, or bone oil, known also as Dippel's animal oil, is a most offensively smelling product of the distillation of bones in the preparation of animal charcoal. The persistent and repulsive stench of this substance effectually precludes its industrial use among the naphthas.

NAPHTHALINE. See TAR.

NAPIER, a seaport and borough of New Zealand, on the south-east coast of North Island, is the chief town of the province of Hawke's Bay, and is built on a peninsula (known as Scinde Island) about 12 miles from the southern end of the bay, in 39° 29′ S. lat. and 176° 44′ E. long., about 200 miles by sea from Wellington. It is a thriving place, the centre of a large agricultural and pastoral district. The main portion of the town, with the banks, churches, hotels, &c., stretches along the flat shore-land, while the suburban dwelling-houses of the wealthier inhabitants scatter themselves over the hills to the north. The stagnant salt lagoons which formerly occupied the southern boundary have been reclaimed. In 1881 the population was 5756; and the municipality, with its area of 879 acres, now contains about 1300 dwellings, with rateable property valued in 1882 at £57,866. An athenæum, a small hospital, a lunatic asylum, a philosophical society, and an acclimatization society are among the public institutions. The town (named after Sir Charles James Napier) is the seat of the bishop of Waiapu, and returns a member to the New Zealand House of Representatives. A railway is now open as far as Makatuku (70 miles). The harbour (Port Ahuriri), 1¼ miles to the west, is very unsatisfactory, and though there is good anchorage the roadstead is greatly exposed to easterly and southerly winds.

NAPIER, SIR CHARLES (1786–1860), British admiral, was the second son of Captain the Hon. Charles Napier, R.N., and grandson of Francis, fifth Lord Napier, and thus cousin to the three famous Napiers, Sir Charles, Sir George, and Sir William, and was born at Merchiston Hall, near Falkirk, on March 6, 1786. He became a midshipman in 1800, was promoted lieutenant in 1805 and commander in 1807, and distinguished himself in the West Indies, where he fought his famous action with three French ships of the line, and took the "Hautpoult," seventy-four guns, into which the admiral promoted him captain. On his return to England his rank was confirmed, but he was put on half-pay. He spent some time at the university of Edinburgh, and then went to Portugal to visit his cousins in Wellington's army. In 1811 he served in the Mediterranean, and in 1813 on the coast of America and in the expedition up the Potomac. The first years of his leisure he spent in Italy and in Paris, but speculated so much in a steamboat enterprise that by 1829 he was quite ruined. In that year he was appointed to the "Galatea," forty-two, and was at the Azores when they were held by the Count de Villa Flor for the queen of Portugal. He so much impressed the constitutional leaders that they begged him to take command of the fleet, which offer he accepted in February 1833. With it he destroyed the Miguelite fleet off Cape St Vincent on July 5, and on the demand of France was struck off the English navy list. Continuing his Portuguese services, he commanded the land forces in the successful defence of Lisbon in 1834, when he was made Grand Commander of the Tower and Sword, and Count Cape St Vincent in the peerage of Portugal. On his return to England he was restored to his former rank in the navy in 1836, and received command of the "Powerful," eighty-four, in 1838. When troubles broke out in Syria he was appointed second in command, and distinguished himself by leading the storming column at Sidon on September 26, 1840, and by other services, for which he was made a K.C.B. He went on half-pay in 1841, and was in 1842 elected M.P. for Marylebone in the Liberal interest, but lost his seat in 1846. He was promoted rear-admiral the same year, and commanded the Channel fleet from 1846 to 1848. On the outbreak of the Russian War he received the command of the fleet destined to act in the Baltic, and hoisted his flag in February 1854. He refused to attack Cronstadt, and a great outcry was raised against him for not obeying the orders of the Admiralty and attempting to storm the key of St Petersburg; but his inaction has been thoroughly justified by posterity. On his return in December 1854 he was not again offered a command. He was elected M.P. for Southwark in February 1855, and maintained his seat, though broken in health, until his death on November 6, 1860.

See Major-General E. Napier's *Life and Correspondence of Admiral Sir Charles Napier, K.C.B.*, 2 vols., London, 1862; Napier's own *War in Syria*, 2 vols., 1842; *The Navy, its past and present state, in a series of letters*, edited by Sir W. F. P. Napier, 1851; and *The History of the Baltic Campaign of 1854, from documents and other materials furnished by Vice-Admiral Sir C. Napier, K.C.B.*, 1857. See also *The Life and Exploits of Commodore Napier*, 1841; and *Life of Vice-Admiral Sir C. Napier*, 1854.

NAPIER, SIR CHARLES JAMES (1782–1853), the acknowledged hero of a family of heroes, was born at Whitehall, London, in 1782, and was the eldest son of Colonel George Napier, of the Guards (a younger son of the fifth Lord Napier), and of his wife Lady Sarah Lennox—the Lady Sarah who had charmed King George III. After the custom of those times Charles Napier had been gazetted an ensign in the 33d regiment in 1794, and in 1797 his father secured for him the appointment of aide-de-camp to Sir James Duff, the general commanding the Limerick district. Longing for more active service, Napier obtained a commission as lieutenant in Manningham's rifles in 1800. This newly formed corps was designed to supply a body of light troops for the English army fit to cope with the French voltigeurs and tirailleurs, and was specially trained at first under the eye of Colonel Manningham, and then in the famous camp at Shorncliffe, under the immediate supervision of Sir John Moore. Moore speedily perceived the military qualities of the Napiers, and inspired the three elder brothers—Charles, George, and William—with an enthusiasm which lasted all their lives; but, though happy in his general, Charles Napier quarrelled bitterly with William Stewart, the lieutenant-colonel, and in 1803 left the regiment to accompany General Fox to Ireland as aide-de-camp. The great influence of his uncle, the duke of Richmond, procured him in 1804 a captaincy in the staff corps, and in the beginning of 1806 a majority in the Cape regiment. On his way to the Cape, however, he exchanged into the 50th regiment, with which he served in the short Danish campaign under Lord Cathcart in 1807. Shortly after his return from Denmark the 50th was ordered to Portugal, and shared all the glories of the famous retreat to Corunna. At the battle of Corunna, one of the last sights of Sir John Moore before he was struck was the advance of his own old regiment under the command of Charles Napier and Edward Stanhope, and almost his last words were "Well done, my majors!" Being badly supported from the right, the 50th were almost entirely cut to pieces, and both the majors left for dead upon the field. Napier's life was saved by a French drummer named Guibert, who brought him safely to the headquarters of Marshal Soult. Soult treated him with the greatest kindness, and he was allowed by Ney to return to England to his "old blind mother" instead of being interned. He had not been long in England when he heard that his exchange had been arranged, and, volunteering for the Peninsula, he joined the light division before Ciudad Rodrigo. As a volunteer he served in the actions on the

prints cross-hatching like Regnesson, or stippling in the manner of Jean Boulanger; but he gradually asserted his full individuality, modelling the faces of his portraits with the utmost precision and completeness, and employing various methods of touch for the draperies and other parts of his plates. Much of the beauty and artistic character of his prints is due to the fact that he was himself a skilful portraitist, accustomed to work much from the life, and that he commonly engraved from his own designs. His subjects are quiet, tender, and silvern in effect, but, compared with those of his great contemporary Edelinck, they are less rich and varied in the rendering of the relative weights of colour. Among the finest works of his fully developed period may be named the portraits of Pomponne de Bellièvre, Gilles Ménage, Jean Loret, the Duc de la Meilleraye, and the Duchesse de Nemours. A list of his works will be found in Dumesnil's *Le Peintre Graveur Français*, vol. iv. He died at Paris in 1678.

NANTUCKET, an island, county, and town of the United States, forming (since 1693) part of Massachusetts. The island, with an area of about 50 square miles, lies within the 10-fathom line, but is separated from the mainland by Nantucket Sound, which measures from 25 to 30 miles in breadth, and has a general depth of from 5 to 8 fathoms. With the exception of a few inconsiderable hills, the surface for the most part consists of open, breezy, and now almost treeless downs. The soil is generally sandy, but affords in some places good pasture. On the north or landward side of the island there is a large lagoon-like harbour formed by a long narrow tongue of land—the Coatue Beach—which, curving north-west, runs out into Great Point, the end of which is marked by a white lighthouse tower in 41° 23′ 24″ N. lat. and 70° 2′ 24″ W. long. Within the harbour the depth at low water is about 12 or 14 feet, but on the bar it is only between 6 and 7. The western end of the island shelves out in a broad submarine platform (Tuckernuck Bank), which supports the two considerable islands of Tuckernuck and Muskeget, both included in the county. Nantucket post-village, the principal settlement, lies at the south-west end of the harbour, —a quiet place, but beginning to attract attention as a summer residence. A library and museum are maintained in the Athenæum building.

Nantucket (Natocko on the map of 1630) was visited by Gosnold (1602), who found it covered with oaks and other trees, and inhabited by about 1500 Indians. Governor Mayhew, in 1659, granted nine-tenths of the island to ten men for £30 and two beaver hats, and shortly afterwards the first settler, Thomas Macy, took possession. The town of Nantucket (known as Sherburne from 1673 to 1795) was incorporated in 1671; the original site was at Maddequet, 5 or 6 miles west of the present position, to which it was removed in the following year. About the same time whaling operations were commenced, and Nantucket gradually became the greatest whaling station in the world. In 1775 it had 150 vessels engaged in the business; but since the beginning of the century its prosperity has rapidly declined: in 1852 there were still 18,105 tons of its registered shipping employed in whale-fishing; in 1863 there were only 3739; and the number has gradually sunk to zero. The last full-blood Indian in Nantucket died in 1821; the last half-breed in 1854. The population of the county was 4500 in 1775, 9012 in 1810, 6094 in 1860, 4123 in 1870, and 3727 in 1880.

NANTWICH, a market-town of Cheshire, situated on two railway lines and on both sides of the Weaver, 20 miles south-east of Chester and 36 south-south-west of Manchester. There is water communication by the Grand Junction Canal, which near it joins the Ellesmere Canal. The town, which consists of three main streets, is somewhat irregularly built. The principal buildings are the church of SS. Mary and Nicholas, in the Decorated Gothic style, with octagonal tower; the grammar school, founded in 1611; the town-hall, in the Gothic style; and the new market-hall, which replaced the old one in 1867. There are several almshouses and other charities. The ancient castle, erected by the Normans, was in ruins before the time of Henry VII., and there are now no remains of it. The principal industry is the manufacture of boots and shoes; there are also several clothing factories. The population of the urban sanitary district in 1871 was 6673, and in 1881 it was 7495

Nantwich, which is said to have existed in the time of the Romans, was originally called Halen Gwyn, the white salt town. In Domesday it is entered as the part possession of the king and Earl Edwin, to whom its numerous salt springs supplied a considerable revenue. It was erected into a barony by Hugh Lupus, first Norman earl of Chester. The town suffered severely from fire in 1438 and in 1583, from a kind of mad ague in 1587, and from plague in 1604. In the reign of Henry VIII. it possessed three hundred salt-works, but, on account of the discovery of salt in 1624 at a district of the Vale of Weaver more convenient for water carriage, the industry rapidly declined, and is now wholly discontinued. Brine baths have been erected (1883) behind the town-hall.

NAPHTALI, the son of Jacob by Bilhah, Rachel's maid, and uterine brother of Dan. The narrator of Gen. xxx. 8 explains the name נַפְתָּלִי by the verb נִפְתַּל, "wrestle." The seats of the tribe lay in the eastern half of upper Galilee, a fertile mountainous country sloping down to the headwaters of Jordan and the Sea of Galilee (Josh. xix. 32–39). Within this country the Canaanites continued to hold Beth-shemesh and Beth-anath (Judg. i. 33). After the wars with Sisera, in which the tribe took a prominent part (Judg. iv.; v. 18), and with Midian (Judg. vii. 23), we hear little of Naphtali. Dwelling near the settlements of the Aramæans, the tribe was an early sufferer in the bloody conflicts of Damascus with Israel (1 Kings xv. 20), and it was depopulated in the first Assyrian captivity by Tiglath Pileser (2 Kings xv. 29; Isa. ix. 1 [viii. 23]).

NAPHTHA, a word originally applied to the limpid liquid portion of the petroleum which exudes abundantly at Baku, &c., on the shores of the Caspian Sea. It is the νάφθα of Dioscorides, and the *naphtha* or *bitumen liquidum candidum* of Pliny. Both in commerce and in science the term is now used somewhat vaguely, but more in a generic sense, to embrace several bodies having certain properties in common, than as a specific name for a particular substance. Naphtha indeed has no distinct place or meaning in modern chemistry. By the alchemists the word was used principally to distinguish various highly volatile, mobile, and inflammable liquids, such as the ethers,—sulphuric ether and acetic ether having been known respectively as *Naphtha sulphurici* and *Naphtha aceti*. In recent times naphtha has been employed to indicate the volatile, limpid, inflammable hydrocarbons obtained by destructive distillation of organic substances artificially conducted, as well as those produced by similar agencies acting within the earth. In commerce the application of the term is still more restricted, and in general it embraces no more than the more volatile portion of the fluid hydrocarbons separated in the distillation of tar.

Under the name naphtha we thus find the subjoined series of substances comprehended. (1) *Coal-tar naphtha* consists of the lightest and first separated portions of the hydrocarbons obtained in the distillation of gas-tar. It embraces the hydrocarbons having a specific gravity ranging from about 850° up to 950°, and is, especially in its lighter fractions, rich in benzole. (2) *Shale naphtha* is obtained in the purification of the crude oil got by the destructive distillation of shale and other carbonaceous minerals. The first fraction secured, having a specific gravity ranging from 640° to 680°, is termed gasoline; and coming between this and the ordinary burning oils is a light volatile and highly inflammable oil with a specific gravity of 700°–760°, known commonly as naphtha, but also more conveniently termed shale spirit. It is valuable as a solvent, and is also used to some extent for burning in open air. (See PARAFFIN.) (3) *Native naphtha* is the more fluid portion of the rock oil or petroleum found in many parts of the world. (4) *Wood naphtha*, or methyl alcohol, has been already described under METHYL, vol. xvi. p. 195. (5) *Caoutchouc naphtha*: a series of hydrocarbons can be prepared by the distillation of india-rubber,

Possibly he had not the coolness which forms a Wellington, but he had the power of inspiring his soldiers with an enthusiastic love and admiration which Wellington could never inspire. Besides being a great soldier he was a very great administrator, and both in Cephalonia and in Sind proved what work a man never fatigued and never afraid of responsibility could do. The most discussed question in his life is the conquest of Sind. There can be no doubt that he hurried on that conquest. There can be no doubt that the conquest was disapproved by statesmen in England. Mr Gladstone's own testimony is to the effect that the conquest of Sind "was disapproved unanimously by the cabinet of Sir Robert Peel, of which I can speak, as I had just entered it at that time. But the ministry were powerless inasmuch as the mischief of retaining was less than the mischief of abandoning it, and it remains an accomplished fact" (*Contemporary Review*, November 1876). But that the mischief was not greater was due to Sir Charles's administrative power. Many men have been gallant generals, great soldiers, and even great administrators, but no man of the 19th century was a hero as well, and it is the heroic side of his character which it is most difficult to analyse, and most easy to perceive. It appears all through Sir William Napier's life of his brother, but it is most clearly and trenchantly brought out in a letter of Carlyle to the biographer. "The fine and noble qualities of the man are very recognizable to me: his subtle piercing intellect turned all to the practical, giving him just insight into men and into things; his inexhaustible adroit contrivances, his fiery valour, sharp promptitude to seize the good moment that will not return. A lynx-eyed fiery man, with the spirit of an old knight in him, more of a hero than any modern I have seen for a long time."

The chief authority for Sir Charles Napier's life is his *Life and Opinions*, by his brother, 1857; consult also MacCall, *Career and Character of C. J. Napier*, 1857; and M'Dougall, *General Sir C. J. Napier, Conqueror and Governor of Scinde*, 1860. His own works are *Memoir of the Roads of Cephalonia*, 1825; *The Colonies*, 1833; *Colonization*, 1835; *Remarks on Military Law and the Punishment of Flogging*, 1837; *A Letter on the Defence of England by Corps of Volunteers and Militia*, 1852; *A Letter to the Right Honourable Sir J. C. Hobhouse on the Baggage of the Indian Army*, 1849; *Defects, Civil and Military, of the Indian Government*, 1853; and *William the Conqueror, a Historical Romance*, edited by Sir W. Napier, 1858. On Sind, consult primarily Sir W. Napier, *The Conquest of Scinde*, 1845; *The Administration of Scinde*, 1851; *Compilation of General Orders issued by Sir C. Napier*, 1850; and Outram, *The Conquest of Scinde, a Commentary*, 1846. For his command-in-chief, and the controversy about his resignation, consult J. Mawson, *Records of the Indian Command of General Sir C. J. Napier*, Calcutta, 1851; *Minutes on the Resignation of the late General Sir C. Napier, by Field-Marshal the Duke of Wellington, &c.* 1854; *Comments by Sir W. Napier on a Memorandum of the Duke of Wellington*, 1854; and Sir William Napier, *General Sir C. Napier and the Directors of the East India Company*, 1857. (H. M. S.)

NAPIER, JOHN (1550–1617), the inventor of logarithms, was born at Merchiston near Edinburgh in 1550, and was the eighth Napier of Merchiston. The first Napier of Merchiston, "Alexander Napare," acquired the Merchiston estate before the year 1438, from James I. of Scotland. He was provost of Edinburgh in 1437, and was otherwise distinguished. His eldest son Alexander, who succeeded him in 1454, was provost of Edinburgh in 1455, 1457, and 1469; he was knighted and held various important court offices under successive monarchs; at the time of his death in 1473 he was master of the household to James III. His son, John Napier of Rusky, the third of Merchiston, belonged to the royal household in the lifetime of his father. He also was provost of Edinburgh at various times, and it is a remarkable instance of the esteem in which the lairds of Merchiston were held that three of them in immediate lineal succession repeatedly filled so important an office during perhaps the most memorable period in the history of the city. He married a great-granddaughter of Duncan, eighth earl of Levenax (or Lennox), and besides this relationship by marriage the Napiers claimed a lineal male cadency from the ancient family of Levenax. His eldest son, Archibald Napier of Edinbellie, the fourth of Merchiston, belonged to the household of James IV. He fought at Flodden and escaped with his life, but his eldest son Alexander (fifth of Merchiston) was killed. Alexander's eldest son (Alexander, sixth of Merchiston) was born in 1513, and fell at the battle of Pinkie in 1547. His eldest son was Archibald, seventh of Merchiston, and the father of John Napier, the subject of this article.

In 1549 Archibald Napier, at the early age of about fifteen, married Janet, daughter of Francis Bothwell, and in the following year John Napier was born. In the criminal court of Scotland, the earl of Argyll, hereditary justice-general of the kingdom, sometimes presided in person, but more frequently he delegated his functions; and it appears that in 1561 Archibald Napier was appointed one of the justice-deputes. In the register of the court, extending over 1563 and 1564, the justice-deputes named are "Archibald Naper of Merchistoune, Alexander Bannatyne, burgess of Edinburgh, James Stirling of Keir, and Mr Thomas Craig." About 1565 he was knighted at the same time as James Stirling, his colleague, whose daughter John Napier subsequently married. In 1582 Sir Archibald was appointed master of the mint in Scotland, with the sole charge of superintending the mines and minerals within the realm, and this office he held till his death in 1608. His first wife died in 1563, and in 1572 he married a cousin, Elizabeth Mowbray, by whom he had three sons, the eldest of whom was named Alexander.[1]

As stated above, John Napier was born in 1550, the year in which the Reformation in Scotland may be said to have commenced. In 1563, the year in which his mother died, he matriculated at St Salvator's College, St Andrews. He early became a Protestant champion, and the one solitary anecdote of his youth that is known to exist occurs in his address "to the Godly and Christian reader" prefixed to his *Plaine Discovery*. He writes:—

"In my tender yeares, and barneage in Sanct-Androis at the Schooles, having, on the one parte, contracted a loving familiaritie with a certaine Gentleman, &c. a Papist; And on the other part, being attentive to the sermons of that worthie man of God, Maister Christopher Goodman, teaching upon the Apocalyps, I was so mooved in admiration, against the blindnes of Papists, that could not most evidently see their seven hilled citie Rome, painted out there so lively by Saint John, as the mother of all spiritual whoredome, that not onely bursted I out in continual reasoning against my said familiar, but also from thenceforth, I determined with my selfe (by the assistance of Gods spirit) to employ my studie and diligence to search out the remanent mysteries of that holy Book: as to this houre (praised be the Lorde) I have bin doing at al such times as conveniently I might have occasion."

The names of nearly all Napier's classfellows can be traced as becoming *determinantes* in 1566 and masters of arts in 1568; but his own name does not appear in the

[1] The descent of the first Napier of Merchiston has been traced to "Johan le Naper del Counte de Dunbretan," who was one of those who swore fealty to Edward I. in 1296 and defended the castle of Stirling against him in 1304; but there is no authority for this genealogy. The legend with regard to the origin of the name Napier was given by Sir Alexander Napier, eldest son of John Napier, in 1625, in these words:—"One of the ancient earls of Lennox in Scotland had issue three sons: the eldest, that succeeded him to the earldom of Lennox; the second, whose name was Donald; and the third, named Gilchrist. The then king of Scotland having wars, did convocate his lieges to battle, amongst whom that was commanded was the earl of Lennox, who, keeping his eldest son at home, sent his two sons to serve for him with the forces that were under his command. This battle went hard with the Scots; for the enemy pressing furiously upon them forced them to lose ground until it came to flat running away, which being perceived by Donald, he pulled his father's standard from the bearer thereof, and valiantly encountering the foe, being well followed by the earl of Lennox's men, he repulsed the enemy and changed the fortune of the day, whereby a great victory was got. After the battle, as the manner is, every one drawing and setting forth his own acts, the king said unto them, ye have all done valiantly, but there is one amongst you who hath Na-Peer [*i.e.*, no equal]; and calling Donald into his presence commanded him, in regard to his worthy service, and in augmentation of his honour, to change his name from Lennox to Napier, and gave him the lands of Gosford, and lands in Fife, and made him his own servant, which discourse is confirmed by evidences of mine, wherein we are called Lennox *alias* Napier." Sir Archibald adds that this is "the origin of our name, as, by tradition from father to son, we have generally and without any doubt received the same." This written statement of the legend was occasioned by the following circumstance. Robert Napier, a cousin of John Napier, had amassed riches abroad as a merchant; he was created a baronet in 1612, and in order to put his genealogy formally on record in the heralds' books, he applied for an authentic certificate to Sir Archibald, afterwards Lord Napier, who resided at Merchiston, as the head of the family; and Sir Archibald in reply wrote out in his own hand the document from which the preceding extract has been made.

Coa, and again at Busaco, where he was badly wounded in the face. He was ordered to England, but refused to go, and was present with the light division in all the actions which took place during Wellington's pursuit of Masséna. His services were rewarded soon after by the lieutenant-colonelcy of the 102d regiment, which had been entirely demoralized at Botany Bay, and when he joined it at Guernsey was one of the worst regiments in the service; when he left it in 1813 it was one of the best. He accompanied it in June 1812 from Guernsey to Bermuda, where he wrought a wonderful change in the spirit both of officers and men. By treating his men as friends he won their love and admiration, and became in a peculiar degree the hero of the British soldiers. In September 1813 he exchanged back into the 50th regiment, and in December 1814, believing all chance of active service to be at an end, retired on half-pay. He was gazetted one of the first C.B.'s on the extension of the order in 1814, and was present as a volunteer at the capture of Cambray, though he just missed the great battle of Waterloo. Though an officer of some experience and more than thirty years of age, he now joined the military college at Farnham, and completed his military education. In 1819 he was appointed inspecting field officer at Corfu. From Corfu he was moved in 1822 to Cephalonia, where he remained for eight years as governor and military resident. What he did there he has described in a book of his own, and how he loved the place is shown by his wish to the very end of his life to return and die there. He was the model of a despotic colonial governor, and showed all the qualities of a benevolent despot. He made good roads and founded great institutions, but everything must be done by him, and he showed himself averse to interference whether from the lord high commissioner of the Ionian Islands or from the inhabitants of his own little colony. An interesting episode in his command was his communication with Lord Byron when he touched at Cephalonia on his way to his death at Missolonghi, and the insurrection of the Greeks, who would have called him to be their commander-in-chief had the Greek committee in London encouraged his pretensions. But at last his struggle with the authorities of the colonies grew to such a pitch that in 1830 he was obliged to leave Cephalonia. He retired to Normandy, where he published his work on the colonies, and also an historical romance on William the Conqueror. In 1834 he refused the governorship of Australia, still hoping for military employment. In 1837 he was promoted major-general with his brother George, and in 1838 was made a K.C.B.; but he was to wait till 1839 before he received an offer of employment. In that year he was made commanding officer in the northern district, and found his command no sinecure, owing to the turbulent state of the Chartists in the towns of Yorkshire and Lancashire. His behaviour during the tenure of his command is described by William Napier in his life of his brother, and his inability to hold a command which did not carry supreme authority is plainly portrayed. In 1841, to the content of the Government, he resigned his command and went to India. He was stationed at Poona, and in September 1842, when troubles were expected there, was ordered to Sind.

His command in Sind from 1842 till August 1847 is the period of his life during which, according to his brother, he made good his title to fame, but his acts, more especially at first, have been most severely criticized. In fact there can be little doubt that from the moment he landed in the province he determined to conquer the ameers, and to seek the first opportunity of doing so. He was to be accompanied by Colonel Outram, who had been resident in Sind during the Afghan war, and who felt a great admiration for him, but who had also a warm affecti for the ameers, and believed that he could put off the day their destruction. On Feb. 15, 1843, Outram was treac erously assailed at Hyderabad, and on the 17th Napi attacked the Baluch army 30,000 strong with but 2800 me With these 2800 men, including the 22d regiment, whic would do anything for him, he succeeded in winning th victory of Meanee. It was a battle of the olden type, i which generals had to fight like privates. Sir Charles wa in his element, and himself engaged in the fray. In th March following he finally destroyed the army of the ameers at the battle of Hyderabad. His success was received with enthusiasm both by the governor-general, Lord Ellenborough, and by the English people, and he was at once made a G.C.B. The conqueror of Sind now had an opportunity to prove his administrative powers, and proceeded to apply the same material means of civilization to Sind which had formerly been successful in Cephalonia. Whether or not the conquest of Sind at that particular period can be justified, there can be no doubt that Charles Napier was the best administrator who could be found for the province when conquered. Sind, when it came under English rule, was in a state of utter anarchy, for the Baluches had formed a military government not unlike that of the Mamelukes in Egypt, which had been extremely tyrannical to the native population. This native population was particularly protected by Sir Charles Napier, who completed the work of the destruction of the Baluch supremacy which he had commenced with the victory of Meanee. The labour of administration was rendered more difficult by the necessity of repressing the hill tribes, which had been encouraged to acts of lawlessness by the licence which followed the Afghan war. The later years of his administration were made very stormy by the attacks on the policy of the conquest which had been made in England. He left Sind, after quarrelling with every authority of the presidency of Bombay, and nearly every authority of the whole of India, in August 1847, and received a perfect ovation on his return from all the hero-worshippers of the Napiers, of whom there were many in England. His short stay in England was occupied with incessant struggles with the directors of the East India Company; but, however much the directors hated him, it was not long before they had to beseech him in humble terms to become their commander-in-chief. The news of the indecisive victory of Chillianwalla created a panic in England, and the East India Company was obliged by the force of public opinion to summon the greatest general to take the command of its armies. Sir Charles started almost at a moment's notice, but on reaching India found that the victory of Gujrat had been won and the Sikh war was over. No taint of envy was in his nature, and he rejoiced that he had not to supersede Lord Gough in the moment of defeat. His restless and imperious spirit was met by one equally imperious in the governor-general, Lord Dalhousie. From the very beginning of his command the governor-general and the commander-in-chief disagreed, and in April 1850 Sir Charles was reprimanded on some trifling point of discipline. The reprimand was reiterated by the duke of Wellington, and in December 1850 Napier once more left for England. His constitution was undermined by the Indian climate, and especially by his fatiguing command in Sind, and on August 29, 1853, he died at Portsmouth.

Charles James Napier, recognized by his brothers as the greatest representative of the Napiers, though without the literary genius of his brother William, had all the restless energy which distinguished the whole family,—the same impatience of command and contradiction, the same power of inspiring the people with a reverential enthusiasm which impressed even the dullest. At Meanee he showed himself to be a gallant general; but he was also a great soldier.

Napierian, that is to say, logarithms to the base e where $e = 2{\cdot}7182818\ldots$; but they are closely related to this system, the connexion being expressed by the equation—

$$\text{log Nap. } n = 10{,}000{,}000 \log_e (10{,}000{,}000) - 10{,}000{,}000 \log_e n\,;$$

or

$$\text{log Nap. } n = 10^7 \log_e\left(\frac{10^7}{n}\right).$$

A translation of the *Canon Mirificus* into English was made by Edward Wright, and published after his death by his son Samuel Wright, at London, in 1618, under the title *A Description of the admirable Table of Logarithmes.* Edward Wright, who was a fellow of Caius College, Cambridge, occupies a conspicuous place in the history of navigation. In 1599 he published *Certaine errors in Navigation detected and corrected*, and he was the author of other works; to him also is chiefly due the invention of the method known as Mercator's sailing. He at once saw the value of logarithms as an aid to navigation, and lost no time in preparing a translation, which he submitted to Napier himself. The preface to Wright's edition consists of a translation of the preface to the *Canon Mirificus*, together with the addition of the following sentences written by Napier himself:—"But now some of our Countreymen in this Island well affected to these studies, and the more publique good, procured a most learned Mathematician to translate the same into our vulgar English tongue, who after he had finished it, sent the Coppy of it to me, to bee seene and considered on by myselfe. I having most willingly and gladly done the same, finde it to bee most exact and precisely conformable to my minde and the originall. Therefore it may please you who are inclined to these studies, to receive it from me and the Translator, with as much good will as we recommend it unto you."

There is a short "preface to the reader" by Briggs, and a description of a triangular diagram invented by Wright for finding the proportional parts. The table is printed to one figure less than in the *Canon Mirificus*. Edward Wright died in 1615, and his son in the preface states that his father "gave much commendation of this work (and often in my hearing) as of very great use for mariners"; and with respect to the translation he says that "shortly after he had it returned out of Scotland, it pleased God to call him away afore he could publish it."

In 1617 Napier published his *Rabdologia*,[1] a duodecimo of one hundred and fifty-four pages; there is prefixed to it as preface a dedicatory epistle to the high chancellor of Scotland. The method which Napier terms "Rabdologia" consists in the use of certain numerating rods for the performance of multiplications and divisions. These rods, which were commonly called "Napier's bones," will be described further on. The second method, which he calls the "Promptuarium Multiplicationis" on account of its being the most expeditious of all for the performance of multiplications, involves the use of a number of lamellæ or little plates of metal disposed in a box. In an appendix of forty-one pages he gives his third method, "local arithmetic," which is performed on a chess-board, and depends, in principle, on the expression of numbers in the scale of radix 2. In the *Rabdologia* he gives the chronological order of his inventions. He speaks of the canon of logarithms as "a me longo tempore elaboratum." The other three methods he devised for the sake of those who would prefer to work with natural numbers; and he mentions that the promptuary was his latest invention. In the preface to the appendix containing the local arithmetic he states that, while devoting all his leisure to the invention of these abbreviations of calculation, and to examining by what methods the toil of calculation might be removed, in addition to the logarithms, rabdologia, and promptuary, he had hit upon a certain tabular arithmetic, whereby the more troublesome operations of common arithmetic are performed on an abacus or chess-board, and which may be regarded as an amusement rather than a labour, for, by means of it, addition, subtraction, multiplication, division, and even the extraction of roots are accomplished simply by the motion of counters. He adds that he has appended it to the *Rabdologia*, in addition to the promptuary, because he did not wish to bury it in silence, nor to publish so small a matter by itself. With respect to the calculating rods, Napier mentions in the dedication that they had already found so much favour as to be almost in common use, and even to have been carried to foreign countries; and that he has been advised to publish his little work relating to their mechanism and use, lest they should be put forth in some one else's name.

John Napier died on April 4, 1617, the same year as that in which the *Rabdologia* was published, so that his death must have taken place very soon after its appearance. His will, which is extant, was signed on the fourth day before his death. No particulars are known of his last illness, but it seems likely that death came upon him rather suddenly at last. In both the *Canon Mirificus* and the *Rabdologia*, however, he makes reference to his ill-health. In the dedication of the former he refers to himself as "mihi jam morbis penè confecto," and in the "Admonitio" at the end he speaks of his "infirma valetudo"; while in the latter he says he has been obliged to leave the calculation of the new canon of logarithms to others "ob infirmam corporis nostri valetudinem."

It is usually stated that John Napier was buried in St Giles's church, Edinburgh, and there can be no doubt that some of the family of Napier were buried there in the 16th or 17th century, but the late Professor Wallace, in a paper read before the Society of Antiquaries of Scotland in 1832, and quoted by Mr Mark Napier on pp. 425–427 of his *Memoirs of John Napier of Merchiston*, gives evidence for believing that he was buried in St Cuthbert's church. Professor Wallace's words are—

"My authority for this belief is unquestionable. It is a Treatise on Trigonometry, by a Scotsman, James Hume of Godscroft, Berwickshire, a place still in possession of the family of Hume. The work in question, which is rare, was printed at Paris, and has the date 1636 on the title-page, but the royal privilege which secured it to the author is dated in October 1635, and it may have been written several years earlier. In his treatise (page 116) Hume says, speaking of logarithms, 'L'inuenteur estoit un Seigneur de grande condition, et duquel la posterité est aujourd'huy en possession de grandes dignitéz dans le royaume, qui estant sur l'age, et grandement trauaillé des gouttes ne pouvait faire autre chose que de s'adonner aux sciences, et principalment aux mathematiques et à la logistique, à quoy il se plaisoit infiniment, et auec estrange peine, a construict ses Tables des Logarymes, imprimees à Edinbourg en l'an 1614 . . . Il mourut l'an 1616, et fut enterré hors la Porte Occidentale d'Edinbourg, dans l'Eglise de Sainct Cudbert.'"

There can be no doubt that Napier's devotion to mathematics was not due to old age and the gout, and that he died in 1617 and not in 1616; still these sentences were written within eighteen years of Napier's death, and their author seems to have had some special sources of information. Additional probability is given to Hume's assertion by the fact that Merchiston is situated in St Cuthbert's parish. It is nowhere else recorded that Napier suffered from the gout.

The *Canon Mirificus* contains only an explanation of the use of the logarithms without any account of the manner in which the canon was constructed. In an "Admonitio" on the seventh page he states that, although in that place the mode of construction should be explained, he proceeds at once to the use of the logarithms, "ut prælibatis prius usu, et rei utilitate, cætera aut magis placeant posthac edenda, aut minus saltem displiceant silentio sepulta." He awaits therefore the judgment and censure of the learned "priusquam cætera in lucem temerè prolata lividorum detrectationi exponantur"; and in an "Admonitio" on the last page of the book he states that he will publish the mode of construction of the canon "si huius inventi usum eruditis gratum fore intellexero."

Napier, as we have seen, died in 1617, immediately after the appearance of the *Rabdologia*, and before he had

[1] *Rabdologiæ, seu Numerationis per virgulas Libri duo: Cum Appendice de expeditissimo Multiplicationis Promptuario. Quibus accessit & Arithmeticæ Localis Liber unus. Authore & Inventore Ioanne Nepero, Barone Merchistonii, &c., Scoto. Edinburgi, Excudebat Andreas Hart*, 1617.

lists. The necessary inference is that his stay at the university was short, and that only the groundwork of his education was laid there. Although there is no direct evidence of the fact, there can be no doubt that he left St Andrews to complete his education on the Continent, and that he probably studied at the university of Paris, and visited Italy and Germany. He did not, however, as has been supposed, spend the best years of his manhood abroad; for he was certainly at home in 1571, when, being just of age, the preliminaries of his marriage were arranged at Merchiston; and for many years after that event he took an earnest interest in the affairs of the church, the most engrossing element in the politics of the time.

In 1572 John Napier married Elizabeth, daughter of Sir James Stirling of Keir, mentioned above. This marriage took place almost immediately after his father's second marriage. About the end of the year 1579 John Napier's wife died, leaving him one son, Archibald, the first Lord Napier, and one daughter, Jane. A few years afterwards he married again, the name of his second wife being Agnes Chisholme, and by her he had ten children, five sons and five daughters.

On the 17th of October 1593 a convention of delegates was held at Edinburgh at which a committee was appointed to follow the king and lay before him in a personal interview certain instructions relating to the punishment of the rebellious Popish earls and the safety of the church. This committee consisted of six members, two barons, two ministers, and two burgesses—the two barons selected being John Napier of Merchiston and James Maxwell of Calderwood. The delegates found the king at Jedburgh, and the mission, which was a dangerous one, was successfully accomplished. Shortly afterwards another convention was held at Edinburgh, and it was resolved that the delegates sent to Jedburgh should again meet the king at Linlithgow and repeat their former instructions. This was done accordingly, the number of members of the committee being, however, doubled. These interviews took place in October 1593, and on the 29th of the following January Napier wrote to the king the letter which forms the dedication of the *Plaine Discovery*.

The full title of this first work of Napier's is given below.[1] It was written in English instead of Latin in order that "hereby the simple of this Iland may be instructed"; and the author states that he "was constrained of compassion, leaving the Latine, to haste out in English this present worke." He apologizes also for the language and his own mode of expression in the following sentences:—

"Whatsoever therfore through hast, is here rudely and in base language set downe, I doubt not to be pardoned thereof by all good men, who, considering the necessitie of this time, will esteem it more meete to make hast to prevent the rising againe of Antichristian darknes within this Iland, then to prolong the time in painting of language"; and "I graunt indeede, and am sure, that in the style of wordes and utterance of language, we shall greatlie differ, for therein I do judge my selfe inferiour to all men: so that scarcely in these high matters could I with long deliberation finde wordes to expresse my minde."[2]

It is not to be supposed that Napier's *Plaine Discovery* was in any respect due to a visionary cloud passing over his mind, or to any temporary infatuation; on the contrary, it is a serious and laborious work, to which he had devoted years of care and thought, and which is closely connected with the history of the times. In one sense it may be said to stand to theological literature in Scotland in something of the same position as that occupied by the *Canon Mirificus* with respect to the scientific literature, for it is the first published original work relating to theological interpretation, and is quite without a predecessor in its own field. In judging of the book, the circumstances of the time and the state of the country have to be taken into account. Napier lived in the very midst of fiercely contending religious factions, and his home was situated in a district which was the scene of constant wars and disturbances; there was but little theological teaching of any kind, and the work related to what were then the leading political and religious questions of the day.

After the publication of the *Plaine Discovery*, Napier seems to have occupied himself with the invention of secret instruments of war, for in the Bacon collection at Lambeth Palace there is a document, dated June 7, 1596, and signed by Napier, giving a list of his inventions for the defence of the country against the anticipated invasion by Philip of Spain. The document is entitled "Secrett Inventionis, proffitabill and necessary in theis dayes for defence of this Iland, and withstanding of strangers, enemies of God's truth and religion,"[3] and the inventions consist of (1) a mirror for burning the enemies' ships at any distance, (2) a piece of artillery destroying everything round an arc of a circle, and (3) a round metal chariot, so constructed that its occupants could move it rapidly and easily, while firing out through small holes in it. It has been asserted (by Sir Thomas Urquhart) that the piece of artillery was actually tried upon a plain in Scotland with complete success, a number of sheep and cattle being destroyed.

In 1614 appeared the work which in the history of British science can be placed as second only to Newton's *Principia*. The full title is as follows:—*Mirifici Logarithmorum Canonis descriptio, Ejusque usus, in utraque Trigonometria; ut etiam in omni Logistica Mathematica, Amplissimi, Facillimi, & expeditissimi explicatio. Authore ac Inventore Ioanne Nepero, Barone Merchistonii, &c., Scoto. Edinburgi, ex officinâ Andreæ Hart Bibliopolæ, CIƆ.DC.XIV.* This is printed on an ornamental title-page. The work is a small-sized quarto, containing fifty-seven pages of explanatory matter and ninety pages of tables.

The nature of logarithms is explained by reference to the motion of points in a straight line, and the principle upon which they are based is that of the correspondence of a geometrical and an arithmetical series of numbers. The table gives the logarithms of sines for every minute to seven figures; it is arranged semi-quadrantally, so that the *differentiæ*, which are the differences of the two logarithms in the same line, are the logarithms of the tangents. Napier's logarithms are not the logarithms now termed

[1] *A plaine discovery of the whole Revelation of Saint John: set downe in two treatises: The one searching and proving the true interpretation thereof: The other applying the same paraphrastically and Historically to the text. Set foorth by John Napeir L. of Marchistoun younger. Whereunto are annexed certaine Oracles of Sibylla, agreeing with the Revelation and other places of Scripture. Edinburgh, printed by Robert Walde-grave, printer to the King's Majestie, 1593. Cum privilegio Regali.*

[2] The work was translated into French by George Thomson, a naturalized Scotsman residing in La Rochelle, and published by him at that town in 1602, under the title *Ouverture de tous les secrets de l'Apocalypse, &c. Par Jean Napier* (c. a. d.) *Nonpareil, Sieur de Merchiston, revue par lui-meme, et mise en Francois par Georges Thomson, Escossois.* There was a second edition of the translation in 1603, and a third edition in 1607. There was also a German translation published at Frankfort, which reached its third edition in 1627. The second English edition appeared in 1611, and in the preface to it Napier states he intended to have published an edition in Latin soon after the original publication in 1593, but that, as the work had now been made public by the French and German translations, and as he was "advertised that our papistical adversaries wer to write larglie against the said editions that are alreadie set out," he defers the Latin edition "till having first seene the adversaries objections, I may insert in the Latin edition an apologie of that which is rightly done, and an amends of whatsoever is amisse." No criticism on the work was ever published, and there was no Latin edition. A third edition appeared in 1645.

[3] A facsimile of this document is given by Mr Mark Napier in his *Memoirs of John Napier*.

to the *Chilias* (1617) Briggs states that the reason why his logarithms are different from those introduced by Napier "sperandum, ejus librum posthumum, abunde nobis propediem satisfacturum." The "liber posthumus" was the *Constructio* (1619), in the preface to which Robert Napier states that he has added an appendix relating to another and more excellent species of logarithms referred to by the inventor himself in the *Rabdologia*, and in which the logarithm of unity is 0. He also mentions that he has published some remarks upon the propositions in spherical trigonometry and upon the new species of logarithms by Henry Briggs, "qui novi hujus Canonis supputandi laborem gravissimum, pro singulari amicitiâ quæ illi cum Patre meo L. M. intercessit, animo libentissimo in se suscepit; creandi methodo, et usuum explanatione Inventori relictis. Nunc antem ipso ex hâc vitâ evocato, totius negotii onus doctissimi Briggii humeris incumbere, et Sparta hæc ornanda illi sorte quadam obtigisse videtur." In the address prefixed to the *Arithmetica Logarithmica* (1625) Briggs bids the reader not to be surprised that these logarithms are different from those published in the *Canon Mirificus*:—

"Ego enim, cum meis auditoribus Londini, publice in Collegio Greshamensi horum doctrinam explicarem; animadverti multo futurum commodius, si Logarithmus sinus totius servaretur 0 (ut in Canone mirifico) Logarithmus autem partis decimæ ejusdem sinus totius, nempe sinus 5 graduum, 44, m. 21, s., esset 10000000000. atque ea de re scripsi statim ad ipsum authorem, et quamprimum per anni tempus, et vacationem a publico docendi munere licuit, profectus sum Edinburgum; ubi humanissime ab eo acceptus hæsi per integrum mensem. Cum autem inter nos de horum mutatione sermo haberetur; ille se idem dudum sensisse, et cupivisse dicebat: veruntamen istos, quos jam paraverat edendos curasse, donec alios, si per negotia et valetudinem liceret, magis commodos confecisset. Istam autem mutationem ita faciendam censebat, ut 0 esset Logarithmus unitatis, et 10000000000 sinus totius: quod ego longe commodissimum esse non potui non agnoscere. Cœpi igitur, ejus hortatu, rejectis illis quos anteà paraveram, de horum calculo serio cogitare; et sequenti æstate iterum profectus Edinburgum, horum quos hic exhibeo præcipuos, illi ostendi. idem etiam tertia æstate libentissime facturus, si Deus illum nobis tamdiu superstitem esse voluisset."

There is also a reference to the change of the logarithms on the title-page of the work.[1]

These extracts contain all the original statements made by Napier, Robert Napier, and Briggs which have reference to the origin of decimal logarithms. It will be seen that they are all in perfect agreement. Briggs pointed out in his lectures at Gresham College that it would be more convenient that 0 should stand for the logarithm of the whole sine as in the *Canon Mirificus*, but that the logarithm of the tenth part of the whole sine (that is to say, of the sine of 5° 44′ 21″) should be 10,000,000,000. He wrote also to Napier at once; and as soon as he could he went to Edinburgh to visit him, where, as he was most hospitably received by him, he remained for a whole month. When they conversed about the change of system, Napier said that he had felt and desired the same thing, but that he had published the tables which he had already prepared, so that they might be used until he could construct others more convenient. But he considered that the change ought to be so made that 0 should be the logarithm of unity and 10,000,000,000 that of the whole sine, which Briggs could not but admit was by far the most convenient of all. Rejecting therefore those which he had prepared already, Briggs began, at Napier's advice, to consider seriously the question of the calculation of new tables. In the following summer he went to Edinburgh and showed Napier the principal portion of the logarithms which he published in 1624. These probably included the logarithms of the first chiliad which he published in 1617.

Unfortunately Hutton in his history of logarithms, which was prefixed to the early editions of his *Mathematical Tables*, and was also published as one of his *Mathematical Tracts*, has charged Napier with want of candour in not telling the world of Briggs's share in the change of system, and he expresses the suspicion that "Napier was desirous that the world should ascribe to him alone the merit of this very useful improvement of the logarithms." According to Hutton's view, the words "*it is to be hoped* that his posthumous work" . . . : which occur in the preface to the *Chilias*, were a modest hint that the share Briggs had had in changing the logarithms should be mentioned, and that, as no attention was paid to it, he himself gave the account which appears in the *Arithmetica* of 1624. There seems, however, no ground whatever for supposing that Briggs meant to express anything beyond his hope that the reason for the alteration would be explained in the posthumous work; and in his own account, written seven years after Napier's death and five years after the appearance of the work itself, he shows no injured feeling whatever, but even goes out of his way to explain that he abandoned his own proposed alteration in favour of Napier's, and, rejecting the tables he had already constructed, began to consider the calculation of new ones. The facts, as stated by Napier and Briggs, are in complete accordance, and the friendship existing between them was perfect and unbroken to the last. Briggs assisted Robert Napier in the editing of the "posthumous work," the *Constructio*, and in the account he gives of the alteration of the logarithms in the *Arithmetica* of 1624 he seems to have been more anxious that justice should be done to Napier than to himself; while on the other hand Napier received Briggs most hospitably and refers to him as "amico mihi longè charissimo."

Hutton's unfair suggestions are all the more to be regretted as they occur in a history which is the result of a good deal of investigation, and which has been referred to as an authority by many English and foreign writers. He seems to have felt a strong prejudice against Napier for some reason, and all his statements with regard to the origin of logarithms and Napier's connexion with them are untrustworthy. While speaking of the change of the logarithms, it should be noticed that the "Admonitio" on the last page of the *Canon Mirificus*, containing the reference to the new logarithms, does not occur in all the copies. It is printed on the back of the last page of the table itself, and so cannot have been torn out from the copies that are without it. As there could have been no reason for omitting it after it had once appeared, we may assume that the copies which do not have it are those which were first issued. It is probable therefore that Briggs's copy contained no reference to the change, and it is even possible that the "Admonitio" may have been added after Briggs had communicated with Napier. As special attention has not been drawn to the fact that some copies have the "Admonitio" and some have not, different writers have assumed that Briggs did or did not know of the promise contained in the "Admonitio" according as it was present or absent in the copies they had themselves referred to, and this has given rise to some confusion. It ought also to be borne in mind that had Napier lived to publish the *Constructio* himself, he would probably have referred to Briggs in much warmer terms than those used by Robert Napier, who doubtless regarded it as due to his father's memory to simply state the facts as he knew them. The character of Briggs is very amiable and perfect; he states with modesty and simplicity his own share in the improvement: and with complete loyalty to his friend, and

[1] The title runs as follows:—*Arithmetica Logarithmica, sive Logarithmorum chiliades triginta. . . . Hos numeros primus invenit clarissimus vir Iohannes Neperus Baro Merchistonij; eos autem ex eiusdem sententia mutavit, eorumque ortum et usum illustravit Henricus Briggius. . . .*

published the promised account of the method of construction of the canon. This work was, however, issued by Robert Napier, his second son by his second marriage, in 1619.[1] The *Constructio* consists of a preface of two pages, followed by sixty-seven pages of text. In the preface Robert Napier says that he has been assured from undoubted authority that the new invention is much thought of by the ablest mathematicians, and that nothing would delight them more than the publication of the mode of construction of the canon. He therefore issues the work to satisfy their desires, although, he states, it is manifest that it would have seen the light in a far more perfect state if his father could have put the finishing touches to it; and he mentions that, in the opinion of the best judges, his father possessed, among other most excellent gifts, in the highest degree the power of explaining the most difficult matters by a certain and easy method in the fewest possible words.

It is important to notice that in the *Constructio* logarithms are called artificial numbers; and Robert Napier states that the work was composed several years (*aliquot annos*) before Napier had invented the name logarithm. The *Constructio* therefore may have been written a good many years previous to the publication of the *Descriptio* in 1614.[2]

The *Canon Mirificus*, on its appearance in 1614, at once attracted the attention of perhaps the two most eminent English mathematicians then living—Edward Wright and Henry Briggs. The former, as we have seen, translated the work into English, but died in 1615 before he could publish his translation. The latter was concerned with Napier in the change of the logarithms from those originally invented to decimal or common logarithms, and it is to him that the original calculation of the logarithmic tables now in use is mainly due (see BRIGGS). He died on January 26, 1631, aged about seventy-four years, so that at the time of the publication of the *Canon Mirificus* he was about fifty-seven years of age. In a letter to Archbishop Ussher, dated Gresham House, March 10, 1615, Briggs wrote, "Napper, lord of Markinston, hath set my head and hands a work with his new and admirable logarithms. I hope to see him this summer, if it please God, for I never saw book which pleased me better, or made me more wonder.[3] I purpose to discourse with him concerning eclipses, for what is there which we may n hope for at his hands"; and he also states "that he wa wholly taken up and employed about the noble inventio of logarithms, lately discovered." In the summer of 161 he went to Merchiston and stayed with Napier a whol month; he repeated his visit in 1616, and, as he states he "would have been glad to make him a third visit, i it had pleased God to spare him so long." William Lilly, the astrologer, in his *Life and Times*, 1721, gives the fol lowing account of the meeting between Napier and Briggs on the occasion of the first visit:—

"I will acquaint you with one memorable story, related unto me by Mr John Marr, an excellent mathematician and geometrician, whom I conceive you remember: he was servant to King James and Charles I. At first, when the Lord Napier, or Marchiston, first made publick his logarithms, Mr Briggs, then reader of the Astronomy lecture at Gresham College in London, was so surprised with admiration of them that he could have no quietness in himself, until he had seen that noble person the Lord Marchiston whose only invention they were: he acquaints John Marr herewith, who went into Scotland before Mr Briggs, purposely to be there when these two so learned persons should meet. Mr Briggs appoints a certain day when to meet at Edinburgh: but failing thereof, the Lord Napier was doubtful he would not come. It happened one day as John Marr and the Lord Napier were speaking of Mr Briggs; 'Ah, John,' saith Marchiston, 'Mr Briggs will not now come'; at the very instant one knocks at the gate; John Marr hasted down and it proved Mr Briggs to his great contentment. He brings Mr Briggs up into my Lord's chamber, where almost one quarter of an hour was spent, each beholding the other almost with admiration, before one word was spoke. At last Mr Briggs began—'My Lord, I have undertaken this long journey purposely to see your person, and to know by what engine of wit or ingenuity you came first to think of this most excellent help unto Astronomy, viz., the Logarithms; but my Lord, being by you found out, I wonder nobody else found it out before, when now known it is so easy.' He was nobly entertained by the Lord Napier, and every summer after that, during the Lord's being alive, this venerable man, Mr Briggs went purposely into Scotland to visit him."

With respect to the change of the logarithms to decimal logarithms, the concluding paragraph of the "Admonitio" which appears on the last page of the *Canon* of 1614 is "Verùm si huius inventi usum eruditis gratum fore intellexero, dabo fortasse brevi (Deo aspirante) rationem ac methodum aut hunc canonem emendandi, aut emendatiorem de novo condendi, ut ita plurium Logistarum diligentia, limatior tandem et accuratior, quàm unius opera fieri potuit, in lucem prodeat. Nihil in ortu perfectum." In some copies, however, this "Admonitio" is absent. In Wright's translation of 1616 Napier has added the sentence—"But because the addition and subtraction of these former numbers may seeme somewhat painfull, I intend (if it shall please God) in a second Edition, to set out such Logarithmes as shall make those numbers above written to fall upon decimal numbers, such as 100,000,000, 200,000,000, 300,000,000, &c., which are easie to be added or abated to or from any other number" (p. 19); and in the dedication to the *Rabdologia* (1617) he wrote "Quorum quidem Logarithmorum speciem aliam multò præstantiorem nunc etiam invenimus, & creandi methodum, unà cum eorum usu (si Deus longiorem vitæ & valetudinis usuram concesserit) evulgare statuimus; ipsam autem novi canonis supputationem, ob infirmam corporis nostri valetudinem, viris in hoc studii genere versatis relinquimus: imprimis verò doctissimo viro D. Henrico Briggio Londini publico Geometriæ Professori, et amico mihi longè charissimo."

Briggs published in 1617, after Napier's death, his *Logarithmorum Chilias Prima*, containing the decimal logarithms of the first thousand numbers to 14 places of decimals. This is the first table of common (or Briggian) logarithms calculated or published. In 1624 he published his *Arithmetica Logarithmica*, containing the logarithms of the first 20,000 numbers and of the numbers from 90,000 to 100,000 to 14 places of decimals. In the short preface

[1] The full title was—*Mirifici logarithmorum canonis constructio; Et eorum ad naturales ipsorum numeros habitudines; unà cum Appendice, de aliâ eâque præstantiore Logarithmorum specie condendâ. Quibus accessere Propositiones ad triangula sphærica faciliore calculo resolvenda: Unà cum Annotationibus aliquot doctissimi D. Henrici Briggii, in eas & memoratam appendicem. Authore & Inventore Ioanne Nepero, Barone Merchistonii, &c. Scoto. Edinburgi, Excudebat Andreas Hart, Anno Domini* 1619. There is also preceding this title-page an ornamental title-page, similar to that of the *Canon Mirificus* of 1614; the words are different, however, and run—*Mirifici logarithmorum canonis descriptio . . . Accesserunt Opera Posthuma: Primò, Mirifici ipsius canonis constructio, & Logarithmorum ad naturales ipsorum numeros habitudines. Secundò, Appendix de aliâ, eâque præstantiore Logarithmorum specie construenda. Tertiò, Propositiones quædam eminentissimæ, ad Triangula sphærica mirâ facilitate resolvenda. . . .* It would thus appear that the *Canonis Descriptio* and the *Canonis Constructio* were issued together in 1619, or that at all events this was the intention.

[2] Both the *Descriptio* and *Constructio* were reprinted by Bartholomew Vincent at Lyons in 1620, and issued together under the title *Logarithmorum Canonis Descriptio, seu Arithmeticarum supputationum mirabilis abbreviatio. Ejusque usus in utraque Trigonometria ut etiam in omni Logistica Mathematica, amplissimi, facillimi & expeditissimi explicatio. Authore ac Inventore Joanne Nepero, Barone Merchistonii, &c. Scoto. Lugduni.* . . . It will be seen that the title of the translation is very different from that of Napier's work of 1614; very many writers have, however, erroneously given it as the title of Napier's original publication.

[3] Dr Thomas Smith thus describes the ardour with which Briggs studied the *Canon Mirificus*:—"Hunc in deliciis habuit, in sinu, in manibus, in pectore gestavit, oculisque avidissimis, et mente attentissima, iterum iterumque perlegit, . . ." *Vitæ quorundam eruditissimorum et illustrium virorum* (London, 1707).

with great earnestness, he devoted the rest of his life to extend the utility of Napier's splendid invention.

Napier's original canon is a table of logarithms of sines, and it was clearly Briggs's original intention to calculate logarithms of sines also; it does not appear from the account he gives who it was who first suggested the tabulation of the logarithms of numbers instead of sines.

Kepler received the invention of logarithms with great enthusiasm. His first mention of them occurs in a letter to Schikhart dated March 11, 1618, in which he writes —"Extitit Scotus Baro, cujus nomen mihi excidit, qui præclari quid præstitit, necessitate omni multiplicationum et divisionum in meras additiones et subtractiones commutata, nec sinibus utitur: at tamen opus est ipsi tangentium canone: et varietas, crebritas, difficultasque additionum subtractionumque alicubi laborem multiplicandi et dividendi superat." This erroneous estimate was formed when he had seen the *Canon Mirificus* but had not read it; and his opinion was very different when he became acquainted with the nature of logarithms. The dedication of his *Ephemeris* for 1620 consists of a letter to Napier dated July 28, 1619, and he there congratulates him warmly on his invention and on the benefit he has conferred upon astronomy generally and also upon his own Rudolphine tables. He says that, although Napier's book had been published five years, he first saw it at Prague two years before; he was then unable to read it, but last year he had met with a little work by Benjamin Ursinus[1] containing the substance of the method, and he at once recognized the importance of what had been effected. He then explains how he verified the canon, and so found that there were no essential errors in it, although there were a few inaccuracies near the beginning of the quadrant, and he proceeds, "Hæc te obiter scire volui, ut quibus tu methodis incesseris, quas non dubito et plurimas et ingeniosissimas tibi in promptu esse, eas publici juris fieri, mihi saltem (puto et cæteris) scires fore gratissimum; eoque percepto, tua promissa folio 57, in debitum cecidisse intelligeres." This letter was written two years after Napier's death, of which Kepler was ignorant, and in the same year as that in which the *Constructio* was published. In 1624 Kepler published a table of Napierian logarithms, with certain modifications and additions.

In a letter from Kepler to Petrus Cugerus there occurs the remarkable sentence—"Nihil autem supra Neperianam rationem esse puto: etsi quidem Scotus quidam literis ad Tychonem A. CIↃIↃXCIV. scriptis jam spem fecit Canonis illius Mirifici." It is here distinctly stated that some Scotsman in the year 1594, in a letter to Tycho Brahe, gave him some hope of the logarithms; and as Kepler joined Tycho after his expulsion from the island of Huen, and had been so closely associated with him in his work, he would be likely to be correct in any assertion of this kind. In connexion with Kepler's statement the following story, told by Anthony Wood in the *Athenæ Oxonienses*, should be noticed:—

"It must be now known, *that* one Dr Craig, a Scotchman . . . coming out of Denmark into his own country, called upon Joh. Neper, Baron of Mercheston, near Edinburgh, and told him, among other discourses, of a new invention in Denmark (by Longomontanus, as 'tis said), to save the tedious multiplication and division in astronomical calculations. Neper being *solicitous to* know farther of him concerning this matter, he could give no other account of it than that it was by *proportional* numbers. Which hint Neper taking, he desired him at his return to call upon him again. Craig, after some weeks had passed, did so, and Neper then showed him a rude draught of what he called *Canon mirabilis Logarithmorum.* Which draught, with some alterations, he printing in 1614, it came forthwith into the hands of our author Briggs, and into those of Will. Oughtred, from whom the relation of this matter came."

Longomontanus was Tycho's assistant, and this story, though obviously untrue in its facts, is of importance, as it connects Dr Craig with Napier and Longomontanus. In the early part of this article Thomas Craig was mentioned as one of the colleagues of Sir Archibald Napier, John Napier's father, in the office of justice-depute. He is well known as the author of a celebrated legal work *De Feudis*, and between his third son John Craig and John Napier a friendship sprang up which may have been due to their common taste for mathematics. There are extant three letters from Dr John Craig to Tycho Brahe, which show that he was on the most friendly terms with him. In the first letter, of which the date is not given, Craig says that Sir William Stewart has safely delivered to him, "about the beginning of last winter," the book which he sent him. Now Mr Mark Napier found in the library of the university of Edinburgh a mathematical work bearing a sentence in Latin of which the translation is "To Doctor John Craig of Edinburgh, in Scotland, a most illustrious man, highly gifted with various and excellent learning, professor of medicine, and exceedingly skilled in the mathematics, Tycho Brahe hath sent this gift, and with his own hand written this at Uraniburg, 2d November 1588." As Sir William Stewart was sent to Denmark to arrange the preliminaries of King James's marriage, and returned to Edinburgh on November 15, 1588, there can be little doubt that this was the volume referred to by Craig. It appears from Craig's letter, to which we may therefore assign the date 1589, that, five years before, he had made an attempt to reach Uraniburg, but had been baffled by the storms and rocks of Norway, and that ever since then he had been longing to visit Tycho. Now John Craig was physician to the king, and in 1590 James VI. spent some days at Uraniburg before returning to Scotland from his matrimonial expedition. It seems not unlikely therefore that Craig may have accompanied the king in his visit to Uraniburg. In any case it is certain that Craig was a friend and correspondent of Tycho's, and there can be but little doubt that he was the "Scotus quidam."

It is therefore clear that as early as 1594 Napier must have communicated to Craig his hope of being able to effect the simplification of the processes of arithmetic. Everything tends to show that the invention of logarithms was the result of many years of labour and thought, undertaken with this special object, and it thus appears that Napier had seen some prospect of success nearly twenty years before the publication of the *Canon Mirificus*. It is very evident that no mere hint with regard to the use of proportional numbers could have been of any service to Napier, but it is possible that the news brought by Craig of the difficulties placed in the progress of astronomy by the labour of the calculations may have stimulated him to persevere in his efforts.

The "new invention in Denmark" to which Anthony Wood refers as having given the hint to Napier was probably the method of calculation called prosthaphæresis (often written in Greek letters *προσθαφαίρεσις*), which had its origin in the solution of spherical triangles.[2] The method consists in the use of the formula

$$\sin a \sin b = \tfrac{1}{2}\{\cos(a-b) - \cos(a+b)\},$$

by means of which the multiplication of two sines is

[1] The title of this work is—*Benjaminis Ursini . . . Cursus Mathematici Practici volumen Primum continens Illustr. & Generosi Dn. Dn. Johannis Neperi Baronis Merchistonij &c. Scoti. Trigonometriam logarithmicam Usibus discentium accommodatam . . . Coloniæ . . CIↃ IↃC XIX.* At the end, Napier's table is reprinted, but to two figures less. As this work was published in 1619, and Vincent's reprint of the *Descriptio* and *Constructio* not till 1620, it forms the earliest publication of logarithms on the Continent.

[2] A careful examination of the history of the method is given by Scheibel in his *Einleitung zur mathematischen Bücherkenntniss*, Stuck vii. (Breslau, 1775), pp. 13–20; and there is also an account in Kästner's *Geschichte der Mathematik*, vol. i. (1796), pp. 566–569; in Montucla's *Histoire des Mathématiques*, vol. i. pp. 583–585 and 617–619; and in Klügel's *Wörterbuch* (1808), article "Prosthaphæresis."

reduced to the addition or subtraction of two tabular results taken from a table of sines; and, as such products occur in the solution of spherical triangles, the method affords the solution of spherical triangles in certain cases by addition and subtraction only. It seems to be due to Wittich of Breslau, who was assistant for a short time to Tycho Brahe; and it was used by them in their calculations in 1582. Wittich in 1584 made known at Cassel the calculation of one case by this prosthaphæresis; and Justus Byrgius proved it in such a manner that from his proof the extension to the solution of all triangles could be deduced. Clavius generalized the method in his treatise *De Astrolabio* (1593), lib. i. lemma liii. The lemma commences as follows:—

"*Quæstiones omnes, quæ per sinus, tangentes, atque secantes absolvi solent, per solam prosthaphæresim, id est, per solam additionem, subtractionem, sine laboriosa numerorum multiplicatione divisioneque expedire.*

"Edidit ante tres quatuorve annos Nicolaus Raymarus Ursus Dithmarsus libellum quendam, in quo præter alia proponit inventum sane acutum, et ingeniosum, quo per solam prosthaphæresim pleraque triangula sphærica solvit. Sed quoniam id solum putat fieri posse, quando sinus in regula proportionum assumuntur, et sinus totus primum locum obtinet, conabimur nos eam doctrinam magis generalem efficere, ita ut non solum locum habeat in sinibus, et quando sinus totus primum locum in regula proportionum obtinet, verum etiam in tangentibus, secantibus, sinibus versis et aliis numeris, et sive sinus totus sit in principio regulæ proportionum, sive in medio, sive denique nullo modo interveniat: quæ res nova omnino est, ac jucunditatis et voluptatis plena."

The work of Raymarus Ursus, referred to by Clavius, is his *Fundamentum Astronomicum* (1588). Longomontanus, in his *Astronomia Danica* (1622), gives an account of the method, stating that it is not to be found in the writings of the Arabs or Regiomontanus. As Longomontanus is mentioned in Anthony Wood's anecdote, and as Wittich as well as Longomontanus were assistants of Tycho, there seems little room for doubt that Wittich's prosthaphæresis is the method referred to by Wood.

In 1610 Herwart ab Hohenburg published at Munich a multiplication table extending to 1000×1000, a huge folio volume of more than a thousand pages; and some writers, misled by the title,[1] have supposed that it contained logarithms. It appears from a correspondence between Kepler and Herwart,[2] which took place at the end of 1608, that Herwart used his table when in manuscript for the performance of multiplications in general, and that the occurrence of the word prosthaphæresis on the title is due to Kepler, who pointed out that by means of the table spherical triangles could be solved more easily than by Wittich's prosthaphæresis.

It is evident that Wittich's prosthaphæresis could not be a good method of practically effecting multiplications unless the quantities to be multiplied were sines, on account of the labour of the interpolations. It satisfies the condition, however, equally with logarithms, of enabling multiplication to be performed by the aid of a table of single entry; and, analytically considered, it is not so different in principle from the logarithmic method. In fact, if we put $xy=\phi(X+Y)$, X being a function of x only and Y a function of y only, we can show that we must have $X=Ae^{ax}$, $y=Be^{ay}$; and if we put $xy=\phi(X+Y)-\phi(X-Y)$, the solutions are $\phi(X+Y)=\frac{1}{4}(x+y)^2$, and $x=\sin X$, $y=\sin Y$, $\phi(X+Y)=-\frac{1}{2}\cos(X+Y)$. The former solution gives a method known as that of quarter-squares; the latter gives the method of prosthaphæresis.

An account of the logarithmic table of Justus Byrgius is given in the article LOGARITHMS.

The more one considers the condition of science at the time, and the state of the country in which the discovery took place, the more wonderful does the invention of logarithms appear. When algebra had advanced to the point where exponents were introduced, nothing would be more natural than that their utility as a means of performing multiplications and divisions should be remarked; but it is one of the surprises in the history of science that logarithms were invented as an arithmetical improvement years before their connexion with exponents was known. It is to be noticed also that the invention was not the result of any happy accident. Napier deliberately set himself to abbreviate multiplications and divisions,—operations of so fundamental a character that it might well have been thought that they were *in rerum natura* incapable of abbreviation; and he succeeded in devising, by the help of arithmetic and geometry alone, the one great simplification of which they were susceptible,—a simplification to which the following two hundred and seventy years have added nothing.

When Napier published the *Canon Mirificus* England had taken no part in the advance of science, and there is no British author of the time except Napier whose name can be placed in the same rank as those of Copernicus, Tycho Brahe, Kepler, Galileo, or Stevinus. In England, Robert Recorde had indeed published his mathematical treatises, but they were of trifling importance and without influence on the history of science. Scotland had produced nothing, and was perhaps the last country in Europe from which a great mathematical discovery would have been expected. Napier lived, too, not only in a wild country, which was in a lawless and unsettled state during most of his life, but also in a credulous and superstitious age. Like Kepler and all his contemporaries he believed in astrology, and he certainly also had some faith in the power of magic, for there is extant a deed written in his own handwriting containing a contract between himself and Robert Logan of Restalrig, a turbulent baron of desperate character, by which Napier undertakes "to serche and sik out, and be al craft and ingyne that he dow, to tempt, trye, and find out" some buried treasure supposed to be hidden in Logan's fortress at Fastcastle, in consideration of receiving one-third part of the treasure found by his aid. In the deed Logan also agrees to conduct Napier from Edinburgh to Fastcastle and back again, without his being despoiled of his third part or otherwise harmed, when the deed is to be cancelled and destroyed as a discharge in full. "And incaiss the said Jhone sal find na poiss to be thair eftir all tryall and utter diligens tane; he referris the satisfactione of his trawell and painis to the discretione of the said Robert." Of this singular contract, which is signed "Robert Logane of Restalrige" and "Jhone Neper, Fear of Merchiston," and is dated July 1594, a facsimile is given in Mr Mark Napier's *Memoirs*.[3] As the deed was not destroyed, but is in existence now, it is to be presumed that the terms of it were not fulfilled; but the fact that such a contract should have been drawn

[1] *Tabulæ arithmeticæ προσθαφαιρεσεως universales, quarum subsidio numerus quilibet, ex multiplicatione producendus, per solam additionem; et quotiens quilibet, e divisione eliciendus, per solam subtractionem, sine tædiosâ & lubricâ Multiplicationis, atque Divisionis operatione, etiam ab eo, qui Arithmetices non admodum sit gnarus, exacte, celeriter & nullo negotio invenitur.*

[2] The correspondence is printed in Frisch's edition of Kepler's works, vol. iv. pp. 527–530. See also a paper "On Multiplication by a Table of Single Entry," in the *Philosophical Magazine* for November 1878.

[3] Of the contract itself Mr Mark Napier writes: "The singularity of his holding conference with one who had just been proclaimed an outlaw, and whose lawless violence is alluded to and provided against by Napier himself, must be accounted for by the rude state of society, and the simplicity of our philosopher's character. He took care to word the contract itself, however, and there is not an expression which indicates an idea beyond the most legitimate purpose; but, under the shield of his own innocence, he never dreamed of contamination from his company, was fond of the romance of science, and not averse (nothing derogatory in his times) to the prospect of gold."—*Memoirs*, p. 223.

up by Napier himself affords a singular illustration of the state of society and the kind of events in the midst of which logarithms had their birth. Considering the time in which he lived, Napier is singularly free from superstition: his *Plaine Discovery* relates to a method of interpretation which belongs to a later age; he shows no trace of the extravagances which occur everywhere in the works of Kepler; and none of his writings contain any allusion to astrology or magic.

After Napier's death his manuscripts and notes came into the possession, not of his eldest son Archibald, but of his second son by his second marriage, Robert, who edited the *Constructio*; and Colonel Milliken Napier, Robert's lineal male representative, was still in the possession of many of these private papers at the close of the last century. On one occasion when Colonel Napier was called from home on foreign service, these papers, together with a portrait of John Napier and a Bible with his autograph, were deposited for safety in a room of the house at Milliken, in Renfrewshire. During the owner's absence the house was burned to the ground, and all the papers and relics were destroyed. The manuscripts had not been arranged or examined, so that the extent of the loss is unknown. Fortunately, however, Robert Napier had transcribed his father's manuscript *De Arte Logistica*, and the copy escaped the fate of the originals in the manner explained in the following note, written in the volume containing them by Francis, seventh Lord Napier:—"John Napier of Merchiston, inventor of the logarithms, left his manuscripts to his son Robert, who appears to have caused the following pages to have been written out fair from his father's notes, for Mr Briggs, professor of geometry at Oxford. They were given to Francis, the fifth Lord Napier, by William Napier of Culcreugh, Esq., heir-male of the above-named Robert. Finding them in a neglected state, amongst my family papers, I have bound them together, in order to preserve them entire.—NAPIER, 7th March 1801."

An account of the contents of these manuscripts was given by Mr Mark Napier in the appendix to his *Memoirs of John Napier*, and the manuscripts themselves were edited in their entirety by him in 1839 under the title *De Arte Logistica Joannis Naperi Merchistonii Baronis Libri qui supersunt. Impressum Edinburgi* M.DCCC.XXX.IX, as one of the publications of the Bannatyne Club. The treatise occupies one hundred and sixty-two pages, and there is an introduction by Mr Mark Napier of ninety-four pages. The *Arithmetic* consists of three books, entitled—(1) De Computationibus Quantitatum omnibus Logisticæ speciebus communium; (2) De Logistica Arithmetica; (3) De Logistica Geometrica. At the end of this book occurs the note—"I could find no more of this geometricall pairt amongst all his fragments." The *Algebra Joannis Naperi Merchistonii Baronis* consists of two books:—(1) "De nominata Algebræ parte; (2) De positiva sive cossica Algebræ parte," and concludes with the words, "There is no more of his algebra orderlie sett doun." The transcripts are entirely in the handwriting of Robert Napier himself, and the two notes that have been quoted prove that they were made from Napier's own papers. The title, which is written on the first leaf, and is also in Robert Napier's writing, runs thus:—"The Baron of Merchiston his booke of Arithmeticke and Algebra. For Mr Henrie Briggs, Professor of Geometrie at Oxforde."

These treatises were probably composed before Napier had invented the logarithms or any of the apparatuses described in the *Rabdologia*; for they contain no allusion to the principle of logarithms, even where we should expect to find such a reference, and the one solitary sentence where the *Rabdologia* is mentioned ("sive omnium facillime per ossa Rhabdologiæ nostræ") was no doubt added afterwards. It is worth while to notice that this reference occurs in a chapter "De Multiplicationis et Partitionis compendiis miscellaneis," which, supposing the treatise to have been written in Napier's younger days, may have been his earliest production on a subject over which his subsequent labours were to exert so enormous an influence.

Napier uses *abundantes* and *defectivæ* for positive and negative, defining them as meaning greater or less than *nothing* ("Abundantes sunt quantitates majores nihilo: defectivæ sunt quantitates minores nihilo"). The same definitions occur also in the *Canon Mirificus* (1614), p. 5.—"Logarithmos sinuum, qui semper majores nihilo sunt, abundantes vocamus, et hoc signo +, aut nullo prænotamus. Logarithmos autem minores nihilo defectivos vocamus, prænotantes eis hoc signum −." Napier may thus have been the first to use the expression "quantity *less than nothing*." He uses "radicatum" for power; for root, power, exponent, his words are radix, radicatum, index.

Apart from the interest attaching to these manuscripts as the work of Napier, they possess an independent value as affording evidence of the exact state of his algebraical knowledge at the time when logarithms were invented. There is nothing to show whether the transcripts were sent to Briggs as intended and returned by him, or whether they were not sent to him. Among the Merchiston papers is a thin quarto volume in Robert Napier's writing containing a digest of the principles of alchemy; it is addressed to his son, and on the first leaf there are directions that it is to remain in his charter-chest and be kept secret except from a few. This treatise and the transcripts seem to be the only manuscripts which have escaped destruction.

The principle of "Napier's bones" may be easily explained by imagining ten rectangular slips of cardboard, each divided into nine squares. In the top squares of the slips the ten digits are written, and each slip contains in its nine squares the first nine multiples of the digit which appears in the top square. With the exception of the top squares, every square is divided into two parts by a diagonal, the units being written on one side and the tens on the other, so that when a multiple consists of two figures they are separated by the diagonal. Fig. 1 shows the slips corresponding to the numbers 2, 0, 8, 5 placed side by side in contact with one another, and next to them is placed another slip containing, in squares without diagonals, the first nine digits. The slips thus placed in contact give the multiples of the number 2085, the digits in each parallelogram being added together; for example, corresponding to the number 6 on the right hand slip, we have 0, 8+3, 0+4, 2, 1; whence we find 0, 1, 5, 2, 1 as the digits, written backwards, of 6×2085. The use of the slips for the purpose of multiplication is now evident; thus to multiply 2085 by 736 we take out in this manner the multiples corresponding to 6, 3, 7, and set down the digits as they are obtained, from right to left, shifting them back one place and adding up the columns as in ordinary multiplication, viz., the figures as written down are—

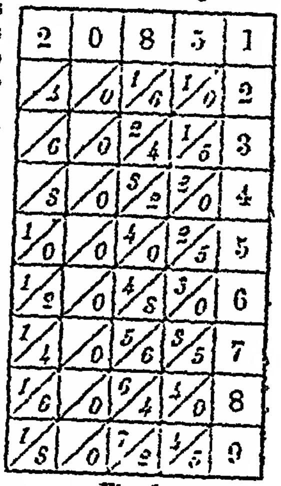


Fig. 1.

12510
6255
14595
1534560

Napier's rods or bones consist of ten oblong pieces of wood or other material with square ends. Each of the four faces of each rod contains multiples of one of the nine digits, and is similar to one of the slips just described, the first rod containing the multiples of 0, 1, 9, 8, the second of 0, 2, 9, 7, the third of 0, 3, 9, 6, the fourth of 0, 4, 9, 5, the fifth of 1, 2, 8, 7, the sixth of 1, 3, 8, 6, the seventh of 1, 4, 8, 5, the eighth of 2, 3, 7, 6, the ninth of 2, 4, 7, 5, and the tenth of 3, 4, 6, 5. Each rod therefore contains on two of its faces multiples of digits which are complementary to those on the other two faces; and the multiples of a digit and of its complement are reversed in position. The arrangement of the numbers on the rods will be evident from fig. 2, which represents the four faces of the fifth bar. The set of ten rods is thus equivalent to four sets of slips as described above, and by their means we may multiply every number less than 11,111, and also any number (consisting of course of not more than ten digits) which can be formed by the top digits of the bars when placed side by side. Of course two sets of rods may be used, and by their means we may multiply every number less than 111,111,111, and so on. It will be noticed that the rods only give the multiples of the number which is to be multiplied, or of the divisor, when they are used for division, and it is evident that they would be of little use to any one who knew the multiplication table as far as 9×9. In multiplications or divisions of any length it is generally convenient to begin by forming a table of the first nine multiples of the multiplicand or divisor, and Napier's bones at best merely provide such a table, and in an incomplete form, for the additions of the two figures in the same parallelogram have to be performed each time the rods are used. The *Rabdologia* attracted more general attention than the logarithms, and there were several editions on the Continent. An Italian translation was published by Locatello at Verona in 1623, and a Dutch translation by De Decker at Gouda in 1626. Ursinus published his *Rhabdologia Neperiana* at Berlin in 1623, and the *Rabdologia* itself was reprinted at Lyons in 1626. Nothing shows more clearly the rude state of arithmetical knowledge at the beginning of the 17th century than the universal satisfaction with which Napier's invention was welcomed by all classes and regarded as a real aid to calculation.

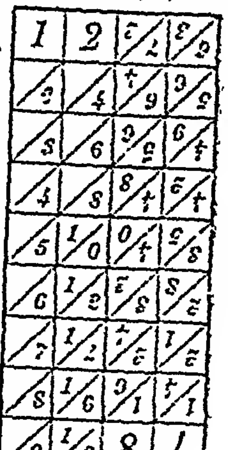

Fig. 2.

Napier also describes in the *Rabdologia* two other larger rods to facilitate the extraction of square and cube roots. In the *Rabdologia* the rods are called "virgulæ," but in the passage quoted above from the manuscript on arithmetic they are referred to as "bones" (ossa).

Besides the logarithms and the calculating rods or bones, Napier's name is attached to certain rules and formulæ in spherical trigonometry. "Napier's rules of circular parts," which include the complete system of formulæ for the solution of right-angled triangles, may be enunciated as follows. Leaving the right angle out of consideration, the sides including the right angle, the complement of the hypotenuse, and the complements of the other angles are called the circular parts of the triangle. Thus there are five circular parts, a, b, $90°-A$, $90°-c$, $90°-B$, and these are supposed to be arranged in this order (*i.e.*, the order in which they occur in the triangle) round a circle. Selecting any part and calling it the middle part, the two parts next it are called the adjacent parts, and the remaining two parts the opposite parts. The rules then are—

sine of the middle part = product of tangents of adjacent parts
= product of cosines of opposite parts.

These rules were published in the *Canon Mirificus* (1614), and Napier has there given a figure, and indicated a method, by means of which they may be proved directly. The rules are curious and interesting, but of very doubtful utility, as the formulæ are best remembered by the practical calculator in their unconnected form.

"Napier's analogies" are the four formulæ—

$$\tan \tfrac{1}{2}(A+B) = \frac{\cos \frac{1}{2}(a-b)}{\cos \frac{1}{2}(a+b)} \cot \tfrac{1}{2}C,$$

$$\tan \tfrac{1}{2}(A-B) = \frac{\sin \frac{1}{2}(a-b)}{\sin \frac{1}{2}(a+b)} \cot \tfrac{1}{2}C;$$

$$\tan \tfrac{1}{2}(a+b) = \frac{\cos \frac{1}{2}(A-B)}{\cos \frac{1}{2}(A+B)} \tan \tfrac{1}{2}c.$$

$$\tan \tfrac{1}{2}(a-b) = \frac{\sin \frac{1}{2}(A-B)}{\sin \frac{1}{2}(A+B)} \tan \tfrac{1}{2}c.$$

They were first published after his death in the *Constructio* among the formulæ in spherical trigonometry, which were the results of his latest work. Robert Napier says that these results would have been reduced to order and demonstrated consecutively but for his father's death. Only one of the four analogies is actually given by Napier, the other three being added by Briggs in the remarks which are appended to Napier's results. The work left by Napier is, however, rough and unfinished, and it is uncertain whether he knew of the other formulæ or not. They are, however, so simply deducible from the results he has given that all the four analogies may be properly called by his name. An analysis of the formulæ contained in the *Descriptio* and *Constructio* is given by Delambre in vol. i. of his *Histoire de l'Astronomie moderne*.

To Napier seems to be due the first use of the decimal point in arithmetic. Decimal fractions were first introduced by Stevinus in his tract *La Disme*, published in 1585, but he used cumbrous exponents (numbers enclosed in circles) to distinguish the different denominations, primes, seconds, thirds, &c. Thus, for example, he would have written 123·456 as 123 (0) 4 (1) 5 (2) 6 (3). In the *Rabdologia* Napier gives an "Admonitio pro Decimali Arithmetica," in which he commends the fractions of Stevinus and gives an example of their use, the division of 861094 by 432. The quotient is written 1993,273 in the work, and 1993,2′7″3‴ in the text. This single instance of the use of the decimal point in the midst of an arithmetical process, if it stood alone, would not suffice to establish a claim for its introduction, as the real introducer of the decimal point is the person who first saw that a point or line as separator was all that was required to distinguish between the integers and fractions, and used it as a permanent notation and not merely in the course of performing an arithmetical operation. The decimal point is, however, used systematically in the *Constructio* (1619), there being perhaps two hundred decimal points altogether in the book.

The decimal point is defined on p. 6 of the *Constructio* in the words:—"In numeris periodo sic in se distinctis, quicquid post periodum notatur fractio est, cujus denominator est unitas cum tot cyphris post se, quot sunt figuræ post periodum. Ut 10000000·04 valet idem, quod $10000000\frac{4}{100}$. Item 25·803, idem quod $25\frac{803}{1000}$. Item 9999998·0005021, idem valet quod $9999998\frac{5021}{10000000}$, & sic de cæteris." On p. 8, 10·502 is multiplied by 3·216, and the result found to be 33·774432; and on pp. 23 and 24 occur decimals not attached to integers, viz., ·4999712 and ·0004950. These examples show that Napier was in possession of all the conventions and attributes that enable the decimal point to complete so symmetrically our system of notation, viz., (1) he saw that a point or separatrix was quite enough to separate integers from decimals, and that no signs to indicate primes, seconds, &c., were required; (2) he used ciphers after the decimal point and preceding the first significant figure; and (3) he had no objection to a decimal standing by itself without any integer. Napier thus had complete command over decimal fractions, and understood perfectly the nature of the decimal point.

Briggs also used decimals, but in a form not quite so convenient as Napier. Thus he prints 63·0957379 as $63\underline{0957379}$, viz., he prints a bar under the decimals; this notation first appears without any explanation in his "Lucubrationes" appended to the *Constructio*. Briggs used the notation all his life, but in writing it, as appears from manuscripts of his, he added also a small vertical line just high enough to fix distinctly which two figures it was intended to separate: thus he might have written $63|\underline{0957379}$. The vertical line was printed by Oughtred and some of Briggs's successors. It was a long time before decimal arithmetic came into general use, and all through the 17th century exponential marks were in common use. There seems but little doubt that Napier was the first to make use of a decimal separator, and it is curious that the separator which he used, the point, should be that which has been ultimately adopted, and after a long period of partial disuse.

The hereditary office of king's poulterer (Pultrie Regis) was for many generations in the family of Merchiston, and descended to John Napier. The office, Mr Mark Napier states, is repeatedly mentioned in the family charters as appertaining to the "pultrelandis" near the village of Dene in the shire of Linlithgow. The duties were to be performed by the possessor or his deputy; and the king was entitled to demand the yearly homage of a present of poultry from the feudal holder. The pultrelands and the office were sold by John Napier in 1610 for 1700 marks. It has been erroneously asserted that Napier dissipated his means; there is no truth in this statement. With the sole exception of the pultrelands all the estates he inherited descended undiminished to his posterity.

With regard to the spelling of the name, Mr Mark Napier states that among the family papers there exist a great many documents signed by John Napier. His usual signature was "Jhone Neper," but in a letter written in 1608, and in all deeds signed after that date, he wrote "Jhone Napair." His letter to the king prefixed to the *Plaine Discovery* is signed "John Napeir." His own children, who sign deeds along with him, use every mode except Napier, the form now adopted by the family, and which is comparatively modern. In Latin he always wrote his name "Neperus." The form "Neper" is the oldest, as John, third Napier of Merchiston, so spelt it in the 15th century.

Napier frequently signed his name "Jhone Neper, Fear of Merchiston." He was "Fear of Merchiston" because, *more majorum*, he had been invested with the fee of his paternal barony during the lifetime of his father, who retained the liferent. He has been sometimes erroneously called "Peer of Merchiston," and in the 1645 edition of the *Plaine Discovery* he is so styled, probably by a misprint (see Mr Mark Napier's *Memoirs*, pp. 9 and 173, and *Libri qui supersunt*, p. xciv).

Napier's home at Merchiston is thus described by Sir Walter Scott in his *Provincial Antiquities of Scotland*:—"This fortalice is situated upon the ascent, and nearly upon the summit of the eminence called the Borough-moor-head, within a mile and a half of the city walls. In form it is a square tower of the 14th or 15th century, with a projection on one side. The top is battlemented, and within the battlements, by a fashion more common in Scotland than in England, arises a small building with a steep roof, like a stone cottage erected on the top of the tower. . . The celebrated John Napier of Merchiston was born in this weather-beaten tower; and a small room in the summit is pointed out as the study in which he secluded himself while engaged in the mathematical researches which led to his great discovery. The battlements of Merchiston tower command an extensive view of great interest and beauty." There is a view of Merchiston tower in Mr Mark Napier's *Memoirs of John Napier*, and in the *Libri qui supersunt*.

One well-known character of the time, Dr Richard Napier, was cousin to John Napier. The eldest son of Alexander, sixth Napier of Merchiston, was Archibald, the father of John Napier; his second son, named Alexander, settled at Exeter, and married an English lady by whom he had two sons, the eldest of whom, Robert, was the merchant, mentioned in the note near the beginning of this article as having been created a baronet. The second son was a fellow of Exeter College, Oxford, and became rector of Lynford, Buckinghamshire. He was a friend and pupil of Dr Simon Forman, a well-known Rosicrucian adept of the time, and at his death became the possessor of his secret manuscripts. Dr Richard Napier, who was more of a physician than a divine, was a great pretender to astrology, necromancy, and magical cures. There is a portrait of him in the Ashmolean Museum, Oxford (engraved in Mr Mark Napier's *Memoirs*), which is interesting on account of the similarity of some of the features to those of John Napier. It does not appear that there was ever any friendship or correspondence between John Napier and Richard Napier.

In 1787 *An Account of the Life, Writings, and Inventions of John Napier of Merchiston* was published at Perth by David Stewart, earl of Buchan, and Walter Minto, LL.D. It is a quarto work of one hundred and thirty-four pages, only twelve of which relate to the life of Napier, the rest being devoted to a careful explanation of the contents of his works. The particulars given of Napier's life are very scanty, but, such as they are, they form the source from which nearly all the notices of Napier which have appeared since have been drawn. The work

has also given rise to the impression that there was but little chance of further information being obtained with respect to Napier's life. In 1834 Mr Mark Napier published his *Memoirs of John Napier of Merchiston, his Life, Lineage, and Times, with a History of the Invention of Logarithms*, a large quarto volume of five hundred and thirty-four pages. Mr Mark Napier, who had already devoted great attention to the history of Scotland with special reference to the families of Lennox and Napier, had full access to all the charters and papers in the possession of the family, and he spared no pains in examining every document and investigating every point which seemed likely to throw light upon the life of Napier and the circumstances amidst which his life was passed. The work contains a vast mass of general information relating to Napier and his relatives, and the people with whom he was brought into contact, besides much collateral matter which serves to illustrate the state of the country at the time. The facts relating to Napier's own life are so interwoven with the other contents of the volume, and the work is so large, that in the absence of an index it is very difficult to extract the comparatively small portion that relates to Napier himself. From this work, which is the sole authority upon the private events of Napier's life, all the facts given in this article with respect to his descent and personal history have been derived. In 1839 Mr Mark Napier completed his labours by editing Napier's unpublished manuscripts, of which he had only been able to give a résumé in the *Memoirs*, and to this he prefixed an introduction, the greater part of which, however, is included in the *Memoirs*. Three different portraits of Napier are known to be in existence; one was engraved as the frontispiece to the earl of Buchan's *Account*, and another forms the frontispiece to the *Memoirs*. There is also an engraving of Napier in Lilly's *Life and Times* (1822). For an account of the contents of Napier's mathematical works and their place in the history of science, the reader is referred to Delambre's *Histoire de l'Astronomie moderne*.

It may be useful to give, in conclusion, a list of Napier's works with a brief statement of the contents of each. The works published in his lifetime are—(1) *The Plaine Discovery* (1593), containing an interpretation of the Book of Revelation; (2) the *Canonis Mirifici Logarithmorum Descriptio*, containing the first announcement of the invention of logarithms and a table of log sines, also the rules of circular parts; (3) the *Rabdologia* (1617), containing the description of Napier's bones, the promptuary, and the method of local arithmetic,—all three designed for the simplification of multiplications and divisions. The posthumous works are—(1) the *Canonis Mirifici Logarithmorum Constructio* (1619), edited by his son Robert, containing an account of the mode of construction of the canon, and Napier's anologies; this book is the first in which the decimal point was systematically employed; (2) the treatise *De Arte Logistica*, edited by Mr Mark Napier in 1839, containing treatises on arithmetic and algebra, transcribed from Napier's notes by his son Robert.

(J. W. L. G.)

NAPIER, SIR WILLIAM FRANCIS PATRICK (1785–1860), the third son of Colonel and Lady Sarah Napier, and brother of Sir Charles and Sir George Napier, was born at Cellbridge, near Dublin, on the 17th of December 1785. He became an ensign in the Royal Irish Artillery in 1800, but at once exchanged into the 62d, and was put on half-pay in 1802. He was afterwards made a cornet in the Blues by his uncle the duke of Richmond, and exchanged into the 52d regiment. He obtained a company in a West India regiment, but exchanged again into the 43d when it was being trained at Shorncliffe under Sir John Moore, who took Napier into special favour, and won his everlasting gratitude. He served in Denmark, and was present at the engagement of Kioge, and, his regiment being shortly afterwards sent to Spain, he bore himself nobly through the retreat to Corunna. In 1809 he became aide-de-camp to his uncle in Ireland, but joined the 43d when ordered again to Spain. With the light brigade (the 43d, 52d, and 95th), under the command of General Craufurd, he marched to Talavera in the famous forced march which he has described in his *History*, and had a violent attack of pleurisy on the way. He, however, refused to leave Spain, was wounded on the Coa, and shot near the spine at Cazal Nova. His conduct was so conspicuous during the pursuit of Masséna after he left the lines of Torres Vedras that he as well as his brother George was recommended for a brevet majority. He became brigade major, was present at Fuentes d'Onor, but had so bad an attack of ague that he was obliged to return to England. In England he fell in love with and married Caroline Fox, the daughter of General Henry Fox, with whom Moore had been in love in Sicily. Three days after his marriage he again started for Spain, and was present at the storming of Badajoz, where his great friend Colonel M'Leod was killed. In the absence of the new lieutenant-colonel he took command of the 43d regiment, and commanded it at the battle of Salamanca. After a short stay at home he again joined his regiment at the Pyrenees, and did his greatest military service at the battle of the Nivelle, where, with instinctive military insight, he secured the most strongly fortified part of Soult's position, practically without orders. He served with his regiment at the battles of the Nive, Orthes, and Toulouse. For his services he was made brevet lieutenant-colonel, and one of the first C.B.'s. Like his brother Charles he then entered the military college at Farnham. He commanded his regiment in the army of occupation in France until 1819, when he retired on half-pay. As it was impossible for him to live on his half-pay with a wife and family, he determined to become an artist, and took a house in Sloane Street, where he studied with George Jones, the academician. The years he had spent in France he had occupied in improving his general education, for it will hardly be believed that the author of the *History of the War in the Peninsula* could not spell or write respectable English till that time. But his career was to be great in literature, not in art. The tendency appeared in an able review of Jomini in 1821, and in 1823 Mr Bickersteth, afterwards Lord Langdale, suggested to him the expediency of writing a history of the Peninsular War. For some time he did not take kindly to the suggestion, but at last determined to become an author in order to defend the memory of Sir John Moore, and to prevent the glory of his old chief being overshadowed by that of Wellington. The duke of Wellington himself gave him much assistance, and handed over to him the whole of Joseph Bonaparte's correspondence which had been taken at the battle of Vittoria; this was all in cipher, but Mrs Napier, with great patience, discovered the keys. In 1828 the first volume of the *History* appeared, and it was at once seen that the great deeds of the Peninsular War were about to be fitly commemorated. The excitement which followed the publication of each volume is proved by the innumerable pamphlets issued by those who believed themselves to be attacked, and by personal altercations with many distinguished officers. But the success of the book was proved still more by the absence of competition than by these bitter controversies. The histories of Southey and Lord Londonderry fell still-born, and Sir George Murray, who had determined to produce *the* history, gave up the attempt in despair. This success was due to a combination of qualities which have justly secured for Napier the title of being the best military historian England has produced. The best military histories have always been written by eye-witnesses. It is impossible for a new generation to analyse the military combinations and understand the minute facts which account for the winning or losing of a battle, though it may often unravel political intrigues which were veiled to the eyes of contemporaries. Napier added to this qualification a wonderful insight into the nature of war, and was able to describe and understand the movements and feelings of the French as well as of the army in which he himself served. But neither contemporary knowledge nor military ability could have made his *History* memorable without a peculiarly appropriate literary style. He knew well how to mingle passages relating to individuals with descriptions of military movements, and how to relieve the dryness of details by an occasional glance at more extended subjects. He possessed an enthusiastic admiration for nearly all the heroes whose deeds he touched on. His admiration for Napoleon was only second to that for Moore, and he could feel for Soult in defeat as well as for Wellington in the hour of victory. When in 1840 the last volume of the *History* was published, his fame not only in England but in France and Germany was safely established. His life during these years had been chiefly absorbed in his *History*, but he had warmly sympathized with the movement for political reform which was agitating England. The Radicals of Bath pressed him to sit for their city, and it was commonly reported that if the reformers had found it necessary to resort to force Colonel Napier would have been their commander-in-chief. In 1842 he was promoted major-general, and had given him the lieutenant-governorship of Guernsey. Here he found plenty of occupation in controlling the relations between

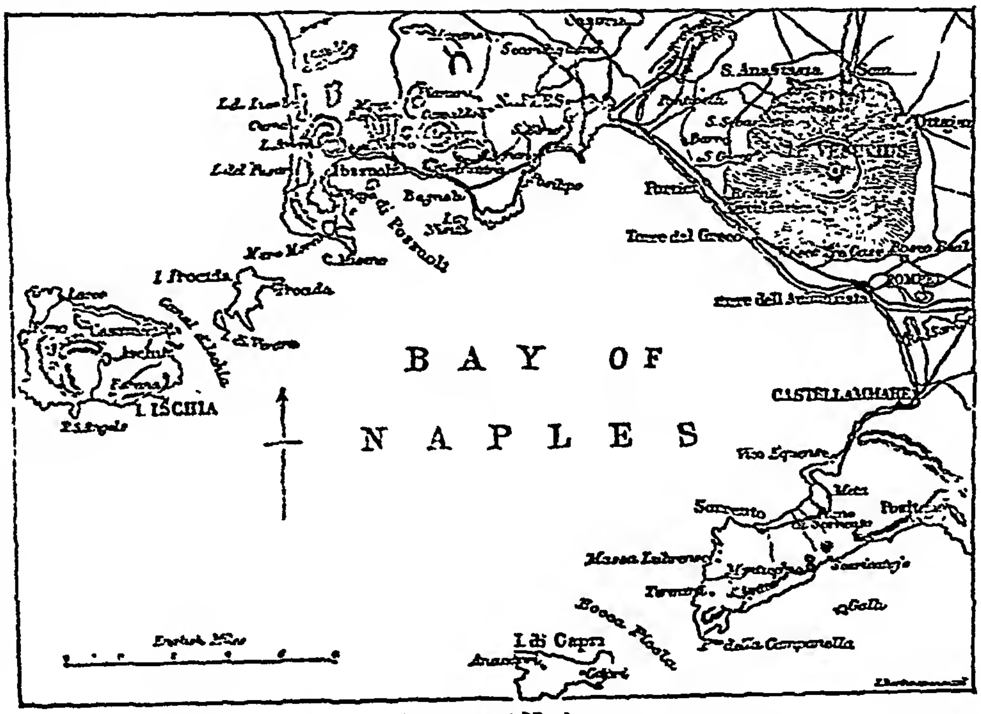
the soldiers and the inhabitants, and also found time to propound a complete scheme of reform for the government of the island. While he was at Guernsey his brother Charles had conquered Sind, and the attacks made on the policy of that conquest brought William Napier again into the field of literature. In 1845 he published his *History of the Conquest of Scinde*, and in 1851 the corresponding *History of the Administration of Scinde*—books which in style and vigour rivalled the great *History*, but which, being written for controversial purposes, are not likely to maintain such an enduring popularity. In 1847 he resigned his governorship, and in 1848 was made a K.C.B., and settled at Scinde House, Clapham Park. His time was fully occupied in defending his brother, in revising the numerous editions of his *History* which were being called for, and in writing letters to the *Times* on every conceivable subject, whether military or literary. His energy is the more astonishing when it is remembered that he never recovered from the effects of the wound he had received at Cazal Nova, and that he often had to lie on his back for months together. His domestic life was shadowed by the incurable affliction of his only son, and when his brother Charles died in 1853 the world seemed to be darkening round him. He devoted himself to writing the life of that brother, which appeared in 1857, and which is in many respects his most characteristic book. In the end of 1853 his younger brother, Captain Henry Napier, R.N., the historian of Florence, died, and in 1855 his brother Sir George. Inspired by his work, he lived on till the year 1860, when, broken by trouble, fatigue, and ill-health, he died (on February 12) at Clapham.

As a military historian Sir William Napier is incomparably superior to any other English writer, and his true compeers are Thucydides, Cæsar, and Davila. All four had been soldiers in the wars they describe: all four possessed a peculiar insight into the mainsprings of action both in war and peace; and all four possessed a peculiar and inimitable style. Napier always wrote as if he was burning with an inextinguishable desire to express what he was feeling, which gives his style a peculiar spontaneity, and yet he rewrote the first volume of his *History* no less than six times. His descriptions of sieges and of battles are admirable by themselves, and his analyses of the peculiarly intricate Spanish intrigues are even more remarkable, while the descriptions and analyses are both lit up with flashes of political wisdom and military insight. It is to be noted that he displays the spirit of the partisan, even when most impartial, and defends his opinions, even when most undoubtedly true, as if he were arguing some controverted question. If his style was modelled on anything, it was on Cæsar's commentaries, and a thorough knowledge of the writings of the Roman general will often explain allusions in Napier. The portraits of Sir John Moore and Colonel M'Leod, and the last paragraphs descriptive of the storming of Badajoz, may be taken as examples of the great natural eloquence which arose from the loving recollection of friends, or the deep impression made by a most terrible scene upon his vivid imagination.

For Sir William Napier's life, see his *Life and Letters*, edited by the Right Honourable H. A. Bruce (now Lord Aberdare), 2 vols., 1862. The dates of his books are given above. The edition of the *History* published in 1851 is the best, and contains the answers to various criticisms which sum up the controversies arising from statements in the work. The French translation is by Count Mathieu Dumas. (H. M. S.)

NAPLES (Ital. *Napoli*, Gr. and Lat. *Neapolis*), formerly the capital of the kingdom of the Two Sicilies, and since 1860 the chief town of a province in the kingdom of Italy, is the largest and most populous city in the country, and disputes with Constantinople the claim of occupying the most beautiful site in Europe. It is situated on the northern shore of the Bay of Naples (*Sinus Cumanus*), in 40° 52′ N. lat. and 14° 15′ 45″ E. long., as taken from the lighthouse on the mole. By rail it is distant 161 miles from Rome.

No other place in the world combines within the same compass so much natural beauty with so many objects of interest to the antiquary, the historian, and the geologist as the Bay of Naples. Its circuit is about 35 miles from the Capo di Miseno on the north-west to the Punta della Campanella on the south-east, or more than 52 miles if the islands of Ischia, at the north-west, and of Capri, at the south entrance, be included. At its opening between these two islands it is 14 miles broad; and from the opening to its head at Portici the distance is 15 miles. It affords good anchorage, with nearly 7 fathoms water, and is well sheltered, except from winds which blow from points between south-east and south-west. There is a perceptible tide of nearly 9 inches.



Environs of Naples.

On the north-east shore of the bay, east of Naples, is an extensive flat, forming part of the ancient *Campania Felix*, and watered by the small stream Sebeto and by the Sarno, which formerly flowed by Pompeii. From this flat, between the sea and the range of the Apennines, rises Vesuvius, at the base of which, on or near the sea-shore, are the town-like villages of San Giovanni Teduccio, Portici, Resina, Torre del Greco, Torre dell' Annunziata, &c., and the classic sites of Herculaneum and Pompeii. At the south-east extremity of the plain, 3 miles beyond the outlet of the Sarno, a great offshoot of the Apennines, branching from the main range near Cava, and projecting as a peninsula more than 12 miles west, divides the Bay of Naples from the Bay of Salerno (*Sinus Pæstanus*), and ends in the bold promontory of the Punta della Campanella (*Promontorium Minervæ*), which is separated by a strait of 4 miles from Capri. On the north slope of this peninsula, where the plain ends and the coast abruptly bends to the west, stands the town of Castellammare, near the site of *Stabiæ*, at the foot of Monte Sant' Angelo, which rises suddenly from the sea to a height of 4722 feet. Farther west, and nearly opposite to Naples across the bay, are Vico, Meta, Sorrento, Massa, and many villages.

The north-west shore of the bay, to the west of Naples, is more broken and irregular. The promontory of Posilipo,

which projects due south, divides this part of the bay into two smaller bays—the eastern, with the city of Naples, and the western, or Bay of Baiæ, which is sheltered from all winds. A tunnel through the promontory, 2244 feet long, 21 feet broad, and in some places as much as 70 feet high, possibly constructed by Marcus Agrippa in 27 B.C., forms the so-called grotto of Posillipo; at the Naples end stands the reputed tomb of Virgil. Beyond Posillipo is the small island of Nisida (*Nesis*); and at a short distance inland are the extinct craters of Solfatara and Astroni, and the Lake of Agnano. Farther west, on a tongue of land, stands Pozzuoli (*Puteoli*); and beyond it, round the Bay of Baiæ, are Monte Nuovo, a hill thrown up in a single night in September 1538; the classic site of Baiæ; the Lucrine Lake; Lake Avernus; the Lake of Fusaro (*Acherusia Palus*); the Elysian Fields; and the port and promontory of Misenum. Still farther to the south-west lie the islands of Procida (*Prochyta*) and Ischia[1] (*Pithecusa*, *Ænaria*, or *Inarime*), which divide the Bay of Naples from the extensive Bay of Gaeta.

The city of Naples is built at the base and on the slopes of a range of volcanic hills, and, rising from the shore like an amphitheatre, is seen to best advantage from the water. From the summit occupied by the castle of St Elmo a transverse ridge runs south to form the promontory of Pizzofalcone, and divides the city into two natural

crescents. The western crescent, known as the Chiaja ward, though merely a long and narrow strip between the sea and Vomero hill, is the fashionable quarter most affected by foreign residents and visitors. A fine broad street, the Riviera di Chiaja, commenced in the close of the 16th century by Count d'Olivares, and completed by the Duke de Medina Celi (1695–1700), runs for a mile and a half from east to west, ending in the quarter of Mergellina and Piedigrotta at the foot of the hill of Posillipo. In front lie the Villa Nazionale (Reale) public gardens, the chief promenade of the city, which were first laid out in 1780, and have been successively extended in 1807, in 1834, and under the new régime; and the whole edge of the bay from the Castel dell' Ovo to Posillipo is lined by a massive embankment and carriage-way, the Via Caracciolo, constructed in 1875–81. The eastern crescent includes by far the largest as well as the oldest portion of Naples—the ports, the arsenal, the principal churches, &c. The main thoroughfare is the Toledo (as it is still popularly called, though the official name is Via di Roma), which runs almost due north from the Piazza (Largo) del Plebiscito in front of the Palazzo Reale, till, as Strada Nuova di Capodimonte,

[1] Since the article ISCHIA (*q.v.*) was written the island has been visited by another severe shock of earthquake (July 28, 1883), which completely ruined Casamicciola, Forio, Lacco Ameno, and Serrara Fontana, and destroyed about 2800 people.

crossing the Ponte della Sanità (constructed by Murat across the valley between Santa Teresa and Capodimonte), it reaches the gates of the Capodimonte palace. A new drive, Corso Vittorio Emmanuele, winds along the slopes behind the city from the Str. di Piedi (at the west end of the Riv. di Chiaja) towards the continuation of the Toledo. The character of the shore of the eastern crescent is being rapidly altered by the new harbour works: about the middle of the curve lies the new Villa del Popolo, or People's Park, constructed on land reclaimed from the bay.

The streets of Naples are generally well-paved with lava or volcanic basalt, which, however, renders them both noisy and slippery for horses. Side-pavements, where they exist, are usually narrow. In the older districts there is a countless variety of narrow gloomy streets, many of them steep. The houses throughout the city are more remarkable for their size and the solidity of their construction than for taste and elegance. They are mostly five or six stories high, are covered with stucco made of a kind of pozzuolana which hardens by exposure, and have large balconies and flat roofs frequently ornamented with flowers, shrubs, and small trees planted in boxes filled with earth. The castle of St Elmo (St Ermo, St Erasmus), which dominates the whole city, had its origin in a fort (Belforte) erected by King Robert the Wise in 1343. The present building, with its rock-hewn fosses and massive ramparts, was constructed by Don Pedro de Toledo at the command of Charles V. in 1535, and was long considered practically impregnable. Damaged by lightning in 1857, it was afterwards restored, but it is no longer used for defensive purposes. On a small island (I. del Salvatore, the *Megaris* of Pliny) now joined to the shore at the foot of the Pizzofalcone by an arch-supported causeway 800 feet long, stands the Castel dell' Ovo (so called from its shape, though mediæval legend associates the name with the enchanted egg on which the magician Virgil made the safety of the city to depend), which, dating from 1154, was for several centuries a place of great strength. The walls of its chapel were frescoed by Giotto; but the whole building was ruined by Ferdinand II. in 1495, and had to be restored in the 16th century. Castel Nuovo, a very picturesque building constructed near the harbour in 1283 by Charles I. of Anjou, contains between the round towers of its façade the triumphal arch erected in 1470 to Alphonso I., and numbers among its chambers the Gothic hall of Giovanni Pisano in which Celestine V. abdicated the papal dignity. Castel del Carmine, founded by Ferdinand I. in 1484, was occupied by the populace in Masaniello's insurrection, was used as a prison for the patriots of 1796, and became municipal property in 1878. The royal palace, begun in 1600 by the Count de Lemos, from designs by Domenico Fontana, partly burned in 1837, and since repaired and enlarged by Ferdinand II., is an enormous building with a sea frontage of 800 feet, and a main façade 554 feet long and 95 feet high, exhibiting the Doric, Ionic, and Composite orders in its three stories. On their visits to Naples, Kings Victor Emmanuel and Humbert have usually preferred the suburban palace of Capodimonte, begun by Charles III. and completed by Ferdinand II. Naples is the see of a Roman Catholic archbishop, always a cardinal. The cathedral has a chapter of thirty canons, and of the numerous religious houses formerly existing thirteen have in whole or in part survived the suppression in 1868. The city is divided into forty-seven parishes (the boundaries of which are administrative and not topographical, so that different stories of the same house are sometimes in different parishes), and there are 257 Roman Catholic churches and 57 chapels. Most of the churches are remarkable rather for richness of internal decoration than for architectural beauty. The cathedral of St Januarius, occupying the site of temples of Apollo and Neptune, and still containing some of their original granite columns, was designed by Nicola Pisano, and erected between 1272 and 1316. Owing to frequent restorations occasioned by earthquakes, it now presents an incongruous mixture of different styles. The general plan is that of a basilica with a nave and two (Gothic vaulted) aisles separated by pilasters. Beneath the high altar is a subterranean chapel containing the tomb of St Januarius (San Gennaro), the patron saint of the city; in the right aisle there is a chapel (Cappella del Tesoro) built between 1608 and 1637 in popular recognition of his having saved Naples in 1527 "from famine, war, plague, and the fire of Vesuvius"; and in a silver tabernacle behind the high altar of this chapel are preserved two phials partially filled with his blood, the periodical liquefaction of which forms a prominent feature in the religious life of the city (see JANUARIUS). Accessible by a door in the left aisle of the cathedral is the church of Sta Restituta, a basilica of the 7th century, and the original cathedral. Santa Chiara (14th century) is interesting for a fresco ascribed to Giotto (at one time there were many more), and monuments to Robert the Wise, his queen Mary of Valois, and his daughter Mary, empress of Constantinople. San Domenico Maggiore, founded by Charles II. in 1285, but completely restored after 1445, has an effective interior particularly rich in Renaissance sculpture. In the neighbouring monastery is shown the cell of Thomas Aquinas. San Filippo Neri or dei Gerolomini, erected in the close of the 16th century, has a white marble façade and two campaniles, and contains the tombstone of Giambattista Vico. Sta Maria del Parto, in the Chiaja, occupies the site of the house of Sannazaro, and is named after his poem *De Partu Virginis*. San Francesco di Paola, opposite the royal palace, is an imitation of the Pantheon at Rome by Pietro Bianchi di Lugano (1815–37), and its dome is one of the boldest in Europe. The church of the Certosa (Carthusian monastery) of San Martino, on the hill below St Elmo's castle, has now become in name, as so many of the churches are in reality, a museum. Dating from the 14th century, and restored by Fonsega in the 17th, it is a building of extraordinary richness of decoration, with paintings and sculpture by Guido Reni, Lanfranco, Caravaggio, D'Arpino, Solimene, Luca Giordano, and notably a Descent from the Cross by Ribera. One of the cloisters by Fonsega is particularly fine. A more ancient Christian monument than any of the convents or churches is the catacombs, which extend a great distance underground. The entrance is at the Ospizio dei Poveri di San Gennaro (see Schulze's monograph, Jena, 1877).

Of all the secular institutions in Naples none is more remarkable than the national museum, better known as the Museo Borbonico. The building, begun in 1586 for cavalry barracks, and remodelled in 1615 for the university, received its present destination in 1790. Enriched by the Farnese collection, by all that was most valuable in Naples, and by everything that would bear removal from Herculaneum, Pompeii, Stabiæ, Puteoli, Pæstum, &c., the museum is unique as a treasure-house of Roman and early Italian antiquities. The collection of Etruscan and Italo-Greek vases is unsurpassed. Nor is the variety of objects greater than the artistic value of some of the items—such as the Farnese Hercules, the Farnese Bull (Amphion and Zethus binding Dirce to its horns), the Dancing Faun (bronze), the statues of the Balbi (marble). For the rich libraries of Naples see vol. xiv. pp. 530, 548. The Club Alpino has a unique collection (25,000 volumes) of Vesuvian and seismographical literature.

The university of Naples is one of the oldest in Italy, having been founded by Frederick II. in the first half of the 13th century. It had fallen to insignificance under the Bourbons, but since 1860 it has rapidly recovered. It comprises five faculties (literature and philosophy, jurisprudence, mathematics, natural science, and medicine), and is well equipped with zoological, mineralogical, and geological museums, a physiological institute, a cabinet of anthropology, botanical gardens, and an observatory on Mount Vesuvius.

The students in 1882–3 numbered 3421. Originally erected in 1557 for the use of the Jesuits, the university buildings are regarded as the best work of Marco di Pino; the quadrangle, surrounded by a simple but effective peristyle, contains statues of Pietro della Vigna (Frederick's chancellor), Thomas Aquinas, Vico, and Giordano Bruno. The famous zoological station at Naples, whose aquarium is the principal building in the Villa Nazionale, is not connected with the university; it was founded in 1872 by Dr Dohrn, and has become one of the greatest centres of biological research in Europe. Its *Mittheilungen* began to be published in 1878, and a great work on the fauna and flora of the Gulf of Naples is in progress. The Royal Society of Naples, dating originally from 1756, was reconstituted in 1861, and now comprises three "academies" or departments, dealing respectively with the physical and mathematical sciences, the moral and political sciences, and literature, archæology, and the fine arts. The famous Accademia Pontaniana, founded in 1471 by Ant. Panormita and J. J. Pontanus, was restored in 1809, and still exists. The royal school of Oriental languages (35 pupils in 1880) owes its existence to Matteo Ripa, who in 1732 established a college for Chinese missionaries with money which he had collected by visiting various European courts in company with ten or twelve young Chinamen. Since 1857 Ludovico da Casoria, relying on public subscriptions, has carried on a special college for the education of Africans (Coll. dei Mori a Capodimonte). The royal college of music, practically founded by Charles III. in 1760, and thus one of the oldest as it is one of the most celebrated institutions of its class, was re-established in 1879. It has a teaching staff of nearly forty persons, takes in boarders (50 Italians gratuitously), and carries on a free day school for males and females. A large and beautiful building in Strada Fuori Porta Medina, erected in a Pompeian style by Francesco del Giudice, accommodates the royal institute for the encouragement of the natural and economical sciences, the royal technical institute (535 pupils), and the nautical institute (46 pupils); and in Str. del Salvatore there is a royal school of engineering with 250 pupils. Four technical schools are maintained by the municipality. The primary education of the people was so much neglected under the Bourbons that after twenty years of a better *régime* there were still 294,384 persons in Naples who could neither read nor write. That some progress had been made was shown in 1881 by the fact that the number of persons under thirty years of age who could both read and write had increased from 79,224 in 1871 to 101,277. In 1872 there were 14,461 children attending school; in 1879 there were 75,311. The educational expenditure of the commune was £64,972 in 1882 for the education of 30,000 children. About one-fourth of the children attending the infant schools are gratuitously supplied with soup at midday, and the children of the working classes are taught free of charge. Among the various private educational enterprises Mrs Salis Schwabe's Froebel Institute, founded in 1873, the Italian Protestant schools, and the institution established by the Marquis Casanova in 1869 to take charge of boys leaving school and bring them up to some special trade, deserve special mention. There are three schools for the blind—notably Lady Strachan's (1865) and the "Prince of Naples," founded by Martuscelli (1873) —and as many for the deaf and dumb.

Charitable institutions are unusually numerous in Naples. The oldest civil hospital is S. Eligio, dating from 1270; but the largest is the Casa Santa degli Incurabili, founded in 1521 by Francesca Maria Longo. It is open to patients of both sexes and any rank, contains upwards of 1000 beds, and has an annual income of about £32,000. In 1877 an international hospital was established by the foreign residents. The Albergo dei Poveri (poorhouse) occupies a magnificent range of buildings, commenced in 1761 by Charles III. at the suggestion of Padre Rocco. Starting with an income of about £3000, it now disposes yearly of £48,000; and it has successively absorbed various minor institutions such as the Conservatorio of St Francis of Sales (1816) and the deaf-mute school (1818). The great almshouse of St Januarius for old men (Ospiz. di S. Gennaro dei Poveri) dates from 1666. Besides the great provincial lunatic asylum (340 patients), now transferred to the convent of St Francis of Sales, there are three smaller asylums in the suburbs. Nothing perhaps is more characteristic of Naples than its so-called *Arci-confraternità*, associations similar to our friendly and burial societies, but entering more into the life of all classes of society. There are about one hundred and thirty of them. The oldest which has kept the date of its origin is that of the Bianchi della Carità, founded in 1382; seven belong to the 15th century and twenty-seven to the 16th. Mutual benefit societies are also numerous.

There are about a score of theatres in Naples. The San Carlo opera-house, with its area of 5157 square yards, and its pit capable of containing one thousand spectators, is one of the largest in Europe. It was originally erected in 1737 under Charles III. after the designs of Giovanni Medrano, but had to be almost completely rebuilt after the fire of 1816. Though closely associated with the names of Rossini, Bellini, Donizetti, Mercadante, &c., San Carlo has always had to be subsidized—first by the Bourbon princes, and since 1860 by the municipality, which also helps to support the Mercadante theatre. It is enough to mention the Teatro Nuovo, the Sannazaro, the Dei Fiorentini (devoted to the Italian drama), and the Bellini (dating from 1876, and second to none in the matter of decoration). The San Carlino, though mean and incommodious, is largely frequented by all classes from royalty downwards, its Pulcinella farces, always in the Neapolitan dialect, being a purely local institution, connected it may be with the Atellan plays.

At a very early date the original harbour at Naples, now known in its greatly reduced state as Porto Piccolo, and fit only for boats and lighters, became too small. In 1302 Charles II. of Anjou began the construction of the Porto Grande by forming the Molo Grande or San Gennaro, which stretched eastward into the bay, and was terminated by a lighthouse in the 15th century. By the addition of a new pier running north-east from the lighthouse, and protected by a heavily armed battery, Charles III. in 1740 added greatly to the safety of the harbour. In 1826 the open area to the south of the Porto Grande was formed into the Porto Militare by the construction of the Molo San Vincenzo, 1200 feet long. Shortly after the formation of the new kingdom of Italy attention was called to the insufficiency of the harbour for modern wants; and new works were commenced in 1862. Besides the lengthening of the Molo San Vincenzo to a total of more than 5000 feet, the scheme as authorized in 1879 includes the formation of a new pier, which is to extend from the Castel del Carmine a distance of about 2460 feet, the construction of quays along the shore between the fort and the Porto Grande, the deepening of the enclosed area to about 25 feet, and the establishment of new bonded warehouses and a floating dock on the Clark-Stanfield system. The contract provides for the completion of the works in 1885. The entrance to the harbour will then measure more than 2000 feet.

The port of Naples is second in the kingdom. The total tonnage of foreign and coasting trade (entrance and clearance) had increased from 1,812,138 register tons in 1863 to 4,128,057 in 1882. In the foreign trade the first place belongs to French shipping, 956,171 tons; the second to British, 374,608; and the third to Italian, 93,424. Cotton, cereals, sugar, coffee, tobacco, wool, &c., are the chief imports; pastes, coral (to the value of £1,500,000), and jewellers' work, dried fruit, hats, tartar and wine lees, wine, and olive oil are the chief exports. The total value of imports and exports was £9,374,940 in 1881 and £8,055,798 in 1882. Coral, kid gloves, and macaroni are manufactured in the city on an extensive scale.

Naples has several good local springs (notably the Acqua del Leone at Mergellina); a covered channel brings the waters of Monte Somma (Vesuvius) to the lower parts of the town; an aqueduct, constructed in the 17th century at the cost of Criminello and Carmignano, taps the Iselero at Sant' Agata dei Goti, 30 miles distant; and a number of artesian wells have proved successful as far as quantity is concerned. But in spite of all these resources the water supply has long been far below the demand; and a city which from its position might be one of the best-drained, cleanest, and healthiest in the world has had an unenviable reputation for dirtiness and unwholesomeness. At present extensive works are in progress by which good drinking water is to be brought from Serino (nearly 50 miles distant) and laid on at three different high levels at the rate of 22,000,000 gallons daily for the use of the inhabitants and 1,000,000 for public purposes.

Naples, the most densely peopled city in Europe, is slowly but steadily increasing. The commune—which includes not only the urban districts (*frazioni*) of S. Ferdinand, Chiaja, S. Giuseppe, Monte Calvario, Avvocata, Stella, San Carlo all' Arena, Vicaria, S. Lorenzo, Mercato, Pendino, and Porto, but also the suburban districts of Vomero, Posillipo, Fuorigrotta, Miano-Mianella, and Piscinola-Marianella—has advanced from 404,000 inhabitants in 1788 to 493,115 in 1881, and the city proper (the first twelve districts) from 326,130 in 1812 to 461,962 in 1881. In the condition of the lower classes considerable improvement has been effected since 1860; the lazzaroni, who bulked so largely in the experience of the tourist in the early part of the century, no longer exist, their place being taken by the dock-labourer, the fisherman, and the artisan.

History.—All ancient writers agree in representing Naples as a Greek settlement, though its foundation is obscurely and differently narrated. It seems that the oldest city on its site was founded by a colony from the neighbouring Greek town of Cumæ. They are said to have given it the name of *Parthenope*, from a legendary connexion of the locality with the siren Parthenope, whose tomb was still shown at the time of Strabo. A number of Chalcidic and Athenian colonists are reported to have afterwards joined the original settlers, and to have built for themselves separate dwellings, which they called *Neapolis*, or the new city, in contradistinction to the old settlement, which in consequence was styled *Palæpolis* or the old city. All modern attempts to define the respective extent and situation of Palæpolis and Neapolis have failed; but Livy's testimony leaves no doubt that they were close to each other, and identical in language and government.

In the year 328 B.C., the Palæpolitans having provoked the hostility of Rome by their incursions upon her Campanian allies,

the consul Publilius Philo marched against them, and, having taken his position between the old and the new city, laid regular siege to Palæpolis. By the aid of a strong Samnite garrison which they received, the Palæpolitans were long able to withstand the attacks of the consul; but at length the city was betrayed into the hands of the Romans by two of her citizens. Neapolis possibly surrendered to the consul without any resistance, as it was received on favourable terms, had its liberties secured by a treaty, and obtained the chief authority, which previously seems to have been enjoyed by the older city. From that time Palæpolis totally disappeared from history, and Neapolis became as an allied city—*fœderata civitas*—a dependency of Rome, to whose alliance it remained constantly faithful, even under most trying circumstances. In 280 B.C. Pyrrhus unsuccessfully attacked its walls; and in the Second Punic War Hannibal was by their strength deterred from attempting to make himself master of the town. During the civil wars of Marius and Sulla, a body of partisans of the latter having entered it by treachery, 82 B.C., made a general massacre of the inhabitants; but Neapolis soon recovered the blow, as it was again a flourishing city in the time of Cicero. It became a *municipium* after the passing of the *lex Julia*; under the empire it is noticed as a *colonia*, but the time when it first obtained that rank is uncertain—possibly under Claudius.

Though a municipal town, Neapolis long retained its Greek culture and institutions; and even at the time of Strabo had gymnasia and quinquennial games, and was divided into *phratriæ*, after the Greek fashion. When the Romans became masters of the world, many of their upper classes, both before the close of the republic and under the empire, from a love of Greek manners and literature or from indolent and effeminate habits, resorted to Neapolis, either for education and the cultivation of gymnastic exercises or for the enjoyment of music and of a soft and luxurious climate. Hence we find Neapolis variously styled—by Horace as "otiosa Neapolis," by Martial as "docta Parthenope," by Ovid as "in otia natam Parthenopen." It was the favourite residence of many of the emperors: Nero made his first appearance on the stage in one of its theatres; Titus assumed the office of its archon; and Hadrian became its demarch. It was chiefly at Neapolis that Virgil composed his *Georgics*; and he was buried on the hill of Pausilypus, the modern Posilipo, in its neighbourhood. It was also the favourite residence of the poets Statius and Silius Italicus, the former of whom was a Neapolitan by birth.

After the fall of the Roman empire, Neapolis suffered severely during the Gothic wars. Having espoused the Gothic cause in the year 536, it was taken, after a protracted siege, by Belisarius, who turned aside an aqueduct, marched by surprise into the city through its channel, and put many of the inhabitants to the sword. In 542 Totila besieged it and compelled it to surrender; but, being soon after recovered by Narses, it remained long a dependency of the exarchate of Ravenna, under the immediate government of a duke, appointed by the Byzantine emperors. When the Lombards invaded Italy, and pushed their conquests in the southern provinces, the limits of the Neapolitan duchy were considerably narrowed. In the beginning of the 8th century, at the time of the Iconoclastic controversy, the emperor Leo the Isaurian having forced compliance to his edict against the worshipping of images, the Neapolitans, encouraged by Pope Gregory III., threw off their allegiance to the Eastern emperors, and established a republican form of government under a duke of their own appointment. Under this régime Neapolis retained her independence for nearly four hundred years, though constantly struggling against the powerful Lombard dukes of Benevento, who twice unsuccessfully besieged it. In 1027, however, Pandulf IV., a Lombard prince of Capua, succeeded in making himself master of it; but he was expelled in 1030 by Duke Sergius, chiefly through the aid of a few Norman adventurers. The Normans, in their turn, gradually superseded all powers, whether Greek, Lombard, or republican, which had previously divided the south of Italy, and furthermore checked the Saracens in the advances they were making through Apulia.

For the consolidation of the Norman authority over Sicily and Naples, the reader is referred to the article NORMANS. It is sufficient here to state that the leaders of the house of Hauteville in 1053 did homage to the pope for all conquests they had made or might make both in the island and upon the mainland, and that in 1130 Count Roger of that family assumed the style of king. In this way the south of Italy, together with the adjacent island of Sicily, was converted into one political body, which, owing to the peculiar temper of its Norman rulers and their powerful organization, assumed a more feudal character than any other part of the peninsula. The "regno," as it was called by the Italians, constituted a state apart, differing in social institutions, foreign relations, and type of home government from the commonwealths and tyrannies of upper Italy. It should furthermore be noticed that the indirect right acquired by the popes as lords paramount over this vast section of Italian territory gave occasion to all the most serious disturbances of Italy between the end of the 13th and the beginning of the 16th centuries, by the introduction of the house of Anjou into Naples and the disputed succession of Angevine and Aragonese princes. From the date at which the south of Italy and Sicily were subjugated by the Normans, the history of Naples ceases to be the history of a republic or a city, and merges itself, as the history of a kingdom, in that of the kingdom of the Two Sicilies. Naples henceforth formed the metropolis of the Italian portion of that kingdom, owing this pre-eminence to its advantageous position on the side of Italy towards Sicily, and to the favour of successive princes. Separated from Sicily between the years 1282 and 1442, reunited to Sicily between 1442 and 1458, again separated between 1458 and 1504, and finally reunited in the year 1504, the kingdom of Naples remained from that date forward, with short interruptions, under one crown, together with Sicily, until 1861. Then both Sicily and Naples were absorbed in the Italian kingdom through the cession by Garibaldi of his conquest to the popularly sanctioned sceptre of the house of Savoy.

It is impossible to write the history of Naples in modern times apart from that of Sicily, or to separate it from that of the several dynasties which have held royal or vice-royal state in Naples as their capital. But an epitome of the main vicissitudes which it has undergone during the last seven centuries and a half may be supplied. The Norman dynasty controlled both Sicily and Naples until the year 1194, when their rights were transmitted, by failure of legitimate male issue, to Henry VI., emperor, and husband of Constance de Hauteville. The popes, in pursuance of their Guelf policy, persecuted the great imperial house of Hohenstaufen to extinction, subdued the Ghibelline party in southern Italy, and conferred the kingdom of the Two Sicilies upon Charles of Anjou after his victory at Grandella, in the year 1265. As a consequence of the Sicilian Vespers, Charles had to relinquish Sicily in 1282; but he continued to be king of Naples. It was then shown that, though the Normans had welded Sicily and the southern provinces of Italy into one substantial political whole, the island and the mainland had no strong bond of national cohesion. The subsequent history of the sister kingdoms makes this even more apparent. Seven princes of the house of Anjou ruled Naples after the death of Charles until the year 1442. Meanwhile Sicily obeyed the house of Aragon, whose rights were derived from Constance, the daughter of Manfred, a bastard son of the emperor Frederick II. In 1442 Alphonso V. of Aragon and Sicily, surnamed the Magnanimous, expelled René of Anjou from the kingdom of Naples, and reunited the Two Sicilies under his own rule. Upon his death in 1458, his brother John became king of Aragon and Sicily; while his natural son Ferdinand assumed the crown of Naples, which was bequeathed to him by Alphonso as being his own property by right of conquest. The bastard Aragonese dynasty thus founded continued to hold sway in Naples, separate from Sicily, through four successive princes, until their line ended by the expulsion of Frederick, Alphonso's grandson, in 1501. Betrayed by his cousin Ferdinand of Spain, this prince surrendered to a French army and died in captivity in France three years later. The French and Spaniards were at this epoch disputing the possession of Italy. Charles VIII. of France had already, in 1494, reasserted the claims of the Angevine line, and had conquered the kingdom of Naples; but he proved unable or unwilling to maintain his conquest more than a few months. His successor Louis XII. covenanted in 1500 to partition Naples with Ferdinand the Catholic of Spain, who was already king of Sicily. Ferdinand, however, having no intention of fulfilling his engagements with his French ally, succeeded in possessing himself of the whole kingdom of Naples, which he now reunited to that of Sicily, and governed together with Castile and Aragon. From 1504 until 1707 Naples and Sicily owed immediate obedience to viceroys of the kings of Spain,—the only important episode in the history of the city throughout this period being the revolt of MASANIELLO (*q.v.*) in 1647. After 1707, during the wars of the Spanish succession, the Austrians made themselves masters of both Sicily and Naples; and, though Sicily was ceded by them in 1713 to the house of Savoy, and in 1718 conquered by Spain, they became again in 1720 possessors of both kingdoms. Naples was at this time of her history administered by Austrian, as previously by Spanish, viceroys. The war of the Polish succession gave monarchial independence once more to the Two Sicilies; for in 1735 Don Carlos, a younger son of Philip V., of the Bourbon dynasty in Spain, after a successful campaign against the Austrians, was crowned sovereign of both kingdoms at Palermo. He founded the Bourbon line, which reigned in Sicily and Naples until the year 1861, interrupted only by the disturbances of the French Revolution and by a brief French occupation (1806–15), during which Joseph Bonaparte bore the title of king of Naples for two years and Joachim Murat for seven years. Sicily throughout this period of French influence remained beneath the sway of her Bourbon princes. For the events which led to the expulsion of the Bourbons and the annexation of both Sicily and Naples to the crown of Italy, the reader is referred to the article ITALY; see also MASANIELLO, NORMANS, SICILY.

NAPOLEON I.

THE family Bonaparte (written by Napoleon's father and by himself down to 1796 Buonaparte, though the other spelling occurs in early Italian documents) was of Tuscan origin. A branch of it was settled in Corsica at least as early as the 16th century, from which time the Bonapartes appear as influential citizens of Ajaccio. They had an ancient title of nobility from the Genoese republic, and Napoleon's grandfather obtained letters of nobility also from the grand-duke of Tuscany. They had therefore the right to sign De Buonaparte, but ordinarily dropped the preposition of honour. Charles Marie de Buonaparte (born in 1746, studied law at the university of Pisa, where he took his doctor's degree in 1769) married at the age of eighteen Letitia Ramolino, who was not quite fifteen. The lady had beauty, but apparently neither rank nor wealth. In the children of this marriage the father, a somewhat indolent Italian gentleman with a certain taste for literature, seems traceable in Joseph, Jerome, and partly also in Lucien; the energy of which Lucien had a share, which Caroline also displayed, and which astonished the world in Napoleon, seems attributable to the Corsican blood of the mother. Thirteen children were born, of whom eight grew up. The list is as follows:—Joseph (king, first of Naples, then of Spain), *Napoleon*, Lucien, Eliza (Princess Bacciochi), Pauline (married, first to General Leclerc, afterwards to Prince Borghese), Caroline (married to Murat, became queen of Naples), Louis (king of Holland), Jerome (king of Westphalia). Of these the eldest was born in 1768, the youngest in 1784. See BONAPARTE.

Besides his brothers and sisters, Napoleon raised to importance Joseph Fesch, half-brother of his mother, a Swiss on the father's side, who was afterwards known to the world as Cardinal Fesch.

ite of ma- rte's rth.

The accepted opinion is that Napoleon was born at Ajaccio on August 15, 1769. This opinion rests indeed on the positive statement of Joseph Bonaparte, but it is certain from documents that on January 7, 1768, Madame Letitia bore a son at Corte, who was baptized by the name of Nabulione. And even in legal documents we find contradictory statements about the time and place of birth, not only of Napoleon, but also of Joseph. All difficulties disappear at once if we suppose that Napoleon and Nabulione were one and the same, and that Joseph was really the second son, whom the parents found it convenient to pass off as the first-born. This they *may* have found convenient when, in 1779, they gained admission for a son to the military school of Brienne. A *son born in 1768* would at that date be inadmissible, as being above ten years of age. Thus it is conceivable that Napoleon was introduced by a fraud to that military career which changed the face of the world. Nevertheless it is certain from Lucien's memoir that of such a fraud nothing was known to the younger members of the family, who regarded Joseph as without doubt the eldest.

ilitary uca- on.

After passing two or three months in a school at Autun for the purpose of learning French—he had hitherto been a thorough Italian—Napoleon entered Brienne on April 23, 1779, where he remained for more than five years, and then in September 1784 passed, as "cadet-gentilhomme," into the military school of Paris. In the next year, 1785, he obtained his commission of lieutenant in the regiment La Fère, stationed at Valence. He had already lost his father, who, undertaking a journey to France on business, was entertained at Montpellier in the house of an old Corsican friend Madame Permon, mother of the celebrated memoir-writer Madame Junot, and died there of the disease which was afterwards fatal to Napoleon, on February 25, 1785, at the age of thirty-eight years.

The fact principally to be noticed about Napoleon's extraction and boyhood is that he was by birth a noble, needy and provincial, and that from his tenth year his education was exclusively military. Of all the great rulers of the world none has been by breeding so purely a military specialist. He could scarcely remember the time when he was not a soldier living among soldiers. The effects of this training showed themselves too evidently when he had risen to the head of affairs. At the same time poverty in a society of luxurious noblemen, and the consciousness of foreign birth and of ignorance of the French language, made his school life at times very unhappy. At one time he demands passionately to be taken away, at another time he sends in a memorial, in which he argues the expediency of subjecting the cadets to a more Spartan diet. His character declared itself earlier than his talents. He was reported as "taciturn, fond of solitude, capricious, haughty, extremely disposed to egoism, seldom speaking, energetic in his answers, ready and sharp in repartee, full of self-love, ambitious, and of unbounded aspirations." So he appeared to his teachers, and an Englishman who remembered him at Brienne makes him a complete Timon, living as a hermit, and perpetually at war with his school fellows. His abilities do not seem to have excited wonder, but he was studious, and in mathematics and geography made great progress. He never, however, so Carnot tells us, became a truly scientific man. He had neither taste nor talent for grammatical studies, but was fond of books, and books of a solid kind. Of the writers of the day he seems to have been chiefly influenced by Raynal and Rousseau.

He is now a lieutenant of artillery in the service of Louis XVI. The next years are spent mainly with his regiment at Valence, Lyons, Douai, Paris, Auxonne, Seurre, Auxonne again. But he takes long holidays with his family at Ajaccio, obtaining permission on the ground of ill-health. Thus he was at Ajaccio in 1787 from February to October, again from December 1787 to May 1788, again from September 1789 to February 1791. During this period he is principally engaged in authorship, being consumed by the desire of distinction, and having as yet no other means of attaining it. He produces *Letters on the History of Corsica*, which he proposes to dedicate first to Paoli, afterwards to Raynal; he competes for a prize offered by the academy of Lyons for the best essay written "to determine the truths and feelings which it is most important to inculcate on men for their happiness." Among his smaller compositions is *The Narrative of the Masked Prophet*. Of all these writings, which are to be distinguished from the pamphlets written by him with a practical object, it may be said that they show more character than literary ability. As the compositions of a boy they are indeed remarkable for their precocious seriousness, but what strikes the reader most in them is a sort of suppressed passion that marks the style, a fierce impatience, as if the writer knew already how much he had to get through in a short life. But his sentiments, love of liberty, of virtue, of domestic happiness, are hollow, and his affectation of tenderness even ridiculous. The essay, as a composition, is positively bad, and was naturally unsuccessful.

Meanwhile his active life had begun with the Revolution of 1789. The first chapter of it is separate from the rest,

and leads to nothing. That astonishing career which has all the unity of a most thrilling drama does not begin till 1795. The six years which preceded it may be called his Corsican period, because for the greater part of it he may be thought to have regarded Corsica as the destined scene of his future life. It must be very summarily treated here.

sican iod.

In 1789 the Italian island of Corsica had been for twenty years a dependency of France. But France had acquired it in a most unscrupulous manner by purchasing the rights of the republic of Genoa over it. She did this in 1768, that is, when Corsica had contested those rights in a war of nearly forty years, and had been practically independent and happy for about thirteen years under the dictatorship of Pasquale Paoli. It was an act similar to the partition of Poland, and seems to mark a design on the part of France—which had just lost its American colonies—to extend its power by way of the Mediterranean into the East. Paoli was compelled to take refuge in England, where he was still living when the French Revolution broke out. In the fall of Corsica a certain Matteo Buttafuoco played a disgraceful part. He had been sent by Paoli to treat as plenipotentiary with France, was won over by Choiseul, declared against the national cause, and appeared in the island as colonel of Louis XV.'s Corsican regiment. He too was still living when the states-general met, and represented there the noblesse of Corsica, while Salicetti, a name of no little prominence in the Revolution, was one of the representatives of the Corsican tiers état.

The Revolution was as dangerous an event to the relation between France and Corsica as to that between France and St Domingo. Would the island assert its independence, and, if so, could the assembly deny its right to do so? The islanders and the exiled Paoli at their head took a moderate view. France must guarantee a good deal of local freedom; on such conditions, they thought, the relation might continue, if only to prevent the republic of Genoa from reviving its pretensions. Accordingly, on November 30, 1789, Corsica was declared by the National Assembly to be a province of France on the motion of Salicetti himself, and the protest against this decree made by Genoa was treated with contempt. Paoli left London, was received in France with an ovation, appeared before the National Assembly on April 22, 1790, where he received the honours of the sitting, and landed in Corsica on July 14th, after an absence of twenty-one years. Thus was Corsica reconciled to France by the Revolution of 1789; but the good work was undone by the Second Revolution of 1792.

Since 1769 the French power in the island had rested mainly on the noblesse and clergy. The Bonaparte family, as noble, had been on the unpatriotic side; Napoleon's father appears always as a courtier of the French governor Marbœuf and as a mendicant at Versailles; Madame Letitia in soliciting a place for her son Louis styles herself "the widow of a man who always served the king in the administration of the affairs of the island of Corsica." It is therefore a remarkable fact that almost immediately after the taking of the Bastille Napoleon hurried to Ajaccio and placed himself at the head of the revolutionary party with all the decision characteristic of him. He devoted himself to the establishment of a National Guard, of which he might hope to be the La Fayette, and he published a letter to Buttafuoco which, properly understood, is a solemn desertion of the principles of his family, similar to that of Mirabeau. This letter has all the intensity of his other early writings, but far more effectiveness. It lashes Buttafuoco for his treason of 1768, describing him as a cynic, who had no belief in virtue, but supposed all men to be guided by selfish interest. The invective has lost its edge for us who know that Bonaparte soon after openly professed this very creed. In declaring for the Revolution he obeyed the real inclination of his feelings at the time, as we may see from his writings, which are in the revolutionary tone of Raynal. But had he not really, we may ask, an ulterior object, viz., to make Corsica independent of France, and to restore the old rule of Paoli, aiming himself at Paoli's succession? Probably he wished to see such a result, but he had always two strings to his bow. In his letter to Buttafuoco he carefully avoids separating Corsican liberty from the liberty offered by the French Revolution. Had the opportunity offered, he might no doubt have stood forth at this time as the liberator of Corsica; but circumstances did not prove favourable, and he drifted gradually in quite the opposite direction.

In October 1790 he met Paoli at Orezza, where Corsica constituted itself as a French department, Paoli being president, Salicetti procureur-général syndic, Arena and Pozzo di Borgo (also from Ajaccio) members of the Directorium. Paoli is said to have hailed Napoleon as "one of Plutarch's men." As the only Corsican officer trained at a royal military school, Napoleon might aspire to become commander of a paid native guard which it was proposed to create for the island. But France had misgivings about the use to which such a guard might be put, and the minister of war rejected the proposal. In the next year, however, he was successful in a second attempt to get the command of an armed force in Corsica, and betrayed in the course of this attempt how much more intent he was at this time upon Corsican than upon French affairs. It was decided to create four battalions of national volunteers for Corsica, and Napoleon became candidate for the post of lieutenant-colonel in the district of Ajaccio. The choice was in the hands of the volunteers themselves, and in pursuing his canvass Napoleon did not hesitate to outstay his furlough, and thus forfeit his French commission by wilful absence from a great review of the whole French army which was appointed for the opening day of 1792. He was, however, elected, having, it is said, executed the first of his many *coups d'état* by violently imprisoning a commissioner sent down to superintend the election. We can understand his eagerness when we remark that anarchy in Corsica was steadily increasing, so that he may have believed that the moment for some military stroke was at hand. He did not long delay. At the Easter festival of 1792 he tried to get possession of Ajaccio under cover of a tumult between the volunteers and the refractory clergy. The stroke failed, and he fled from the island. The European war was just breaking out, and at Paris everything was in confusion; otherwise he would probably have been tried by court-martial and shot.

A rebel in Corsica, a deserter in France, what was he to do? He went to Paris, where he arrived on May 21. The Second Revolution was at hand, and he could observe while no one had leisure to observe him. He witnessed the 10th of August and the downfall of the monarchy. To him this revolution was a fortunate event, for the new Government, attacked by all Europe, could not dispense with the few trained officers whom the emigration had left. On August 30th his name was restored to the army list with the rank of captain, a commission dated back to the 6th February, and arrears of pay. He was saved from the most desperate condition to which he was ever in his whole life reduced. On September 2d (terrible date!) he is engaged in withdrawing his sister Eliza from St Cyr (the House of St Louis having been suppressed). The next step he takes is remarkable. The great war which was to carry him to the pinnacle of fame was now in full progress. By undeserved good luck his military rank is

restored to him. Will he not hurry to his regiment, eager to give proof of his military talents? No, his thoughts are still in Corsica. On the pretext of conducting his sister to her home he sets off without delay for Ajaccio, where he arrives on the 17th. The winter was spent in the unsuccessful expedition, which may be called Napoleon's first campaign, made from Corsica against the island of Sardinia. On his return he found a new scene opened. The Second Revolution was beginning to produce its effect in Corsica, which was no mere province of France, and in which everything was modified by the presence of Paoli. Elsewhere the Convention was able by its Representatives in Mission to crush opposition, but they could not so crush Corsica and Paoli. There was thus a natural opposition between the Convention and Paoli, and the islanders began to fall into opposite parties, as adherents of the former or of the latter. It might have been expected that Bonaparte, who all his life had glorified Paoli, and whose early letters are full of hatred to France, would have been an enthusiastic Paolist. But a breach seems to have taken place between them soon after Napoleon's return from Paris, perhaps in consequence of his escapade of Easter 1792. The crisis came on April 2d, when Paoli was denounced before the Convention, among others by Marat, and it was decreed that he and Pozzo di Borgo should come to Paris and render an account of their conduct to the Convention. Paoli refused, but with the remarkable, perhaps excessive, moderation which characterized him offered to leave Corsica if his presence there appeared to the Convention undesirable. But the islanders rallied round him almost as one man.

There could be no reason why the horrors of the Second Revolution should extend to Corsica, even if we consider them to have been inevitable in France. For a Corsican patriot no fairer opportunity could offer of dissolving with universal approbation the connexion with France which had begun in 1769. Napoleon took the opposite side. He stood out with Salicetti as the leading champion of the French connexion and the bitterest opponent of Paoli. Was his motive envy, or the bitterness caused by a recent personal quarrel with Paoli? We cannot positively say, but we can form an estimate of the depth of that insular patriotism which fills the *Letters on the History of Corsica*. Paoli summoned a national consulta at the end of May, and the dissolution of the French connexion now began. The consulta denounced the Bonaparte family by name. Napoleon answered by desperate attempts to execute his old plan of getting possession of the citadel of Ajaccio. But he failed, and the whole Bonaparte family, with Madame Letitia and Fesch, pursued by the fury of the people, took refuge in France. With this Hijra the first period of Napoleon comes to an end.

Up to this time Napoleon has regarded the French nation with dislike, French ways and habits are strange and foreign, and he has more than once turned aside from a French career when it seemed open to him. Henceforth he has no other career to look for, unless indeed it may be possible, as for some time he continued to hope, to make his way back to Corsica by means of French arms. A certain change seems now to pass over his character. Up to this time his writings, along with their intensity, have had a highly moral and sentimental tone. He seems sincerely to have thought himself not only stronger and greater but better than other men. At school he found himself among school-fellows who were a hundred "fathoms below the noble sentiments which animated himself," and again much later he pronounced that "the men among whom he lived had ways of thinking as different from his own as moonlight is from sunlight." Probably he still felt that he had more vivid thoughts than other men, but he ceases henceforth to be a moralist. His next pamphlet, *Le Souper de Beaucaire*, is entirely free from sentiment, and in a very short time he appears as a cynic, and even pushing cynicism to an extreme.

It was in June 1793 that the Bonaparte family found themselves at Toulon in the midst of the Corsican emigration. France was in a condition not less disturbed than Corsica, for it was the moment of the fall of the Girondins. Plunged into this new party strife, Bonaparte could hardly avoid taking the side of the Mountain. Paoli had been in a manner the Girondin of Corsica, and Bonaparte had headed the opposition to him. In *Le Souper de Beaucaire* (published in August 1793), which is the manifesto of this period as the *Letter to Buttafuoco* is of the earlier period, he himself compares the Girondins to Paoli, and professes to think that the safety of the state requires a deeper kind of republicanism than theirs. The immediate occasion of this pamphlet is the civil war of the south, into which he was now plunged. Marseilles had declared against the Convention, and had sent an army under Rousselet which had occupied Avignon, but had evacuated it speedily on being attacked by the troops of the Mountain under Carteaux. Bonaparte took part in the attack, commanding the artillery, but it seems an unfounded statement that he specially distinguished himself. This was in July, and a month later the pamphlet was written. It is a dialogue between inhabitants of Marseilles, Nîmes, and Montpellier and a military man. It is highly characteristic, full of keen and sarcastic sagacity, of clear military views; but the temperature of its author's mind has evidently fallen suddenly; it has no warmth, but a remarkable cynical coldness. Among the Representatives in Mission recently arrived at Avignon was the younger Robespierre, with whom Salicetti was intimate. Bonaparte, introduced by Salicetti and recommended by this pamphlet, naturally rose high in his favour. He is now a Jacobin. We must not be misled by the violence with which Bonaparte attacked this party some years later, and the horror he professed to feel for their crimes, so as to conclude that his connexion with the Jacobins, and especially the Robespierres, was purely accidental and professional. What contemporary evidence we have exhibits Bonaparte at this time as holding the language of a terrorist, and we shall see how narrowly he escaped perishing with the Robespierres in Thermidor. Of course it is not necessary to disbelieve Marmont when he says that the atrocities of the Robespierrists were not to Bonaparte's taste, and that he did much to check them within the sphere of his influence.

At Tou

Bonaparte marched with Carteaux into Marseilles late in August, and about the same time Toulon delivered itself into the hands of the English. Just at this moment he was promoted to the rank of *chef de bataillon* in the second regiment of artillery, which gave him practically the command of the artillery in the force which was now formed to besiege Toulon. The story of his relations with the generals who were sent successively to conduct the siege, Carteaux the painter, Doppet the physician, Dugommier the brave veteran, and of his discovery of the true way to take Toulon, are perhaps somewhat legendary, but he may probably have been eloquent and persuasive at the council of war held November 25th, in which the plan of the siege was laid down. That he distinguished himself in action is more certain, for Dugommier writes, "Among those who distinguished themselves most, and who most aided me to rally the troops and push them forward, are citizens Buona Parte, commanding the artillery, Arena and Cervoni, adjutants general" (*Moniteur*, December 7, 1793). He was now named general of brigade.

s the y of r.

Bonaparte now passes out of the civil into the foreign war. The military system of the Convention is by this time in full operation. Distinct armies face each enemy, and the great military names of the Revolution are already in men's mouths. The army of the north has Jourdan, Leclerc, Vandamme, Brune, Mortier; that of the Moselle has Hoche, Bessières, Moreau; that of the Rhine Pichegru, Schérer, Berthier; that of the West Marceau and Kléber. Bonaparte joins the army of Italy as general of artillery and inspector-general; to the same army is attached Masséna as general of division; Dumerbion is general-in-chief. It is now that for the first time we find Bonaparte's exceptional ability remarked. Restless pushing ambition he had shown all along, but that he was more than a mere intriguer seems to have been first discerned by the younger Robespierre, who in a letter of April 5, 1794, describes him as "of transcendent merit." In the brief campaign of the army of Italy which occupied the month of July 1794 he took no part, while Masséna commanded in the illness of Dumerbion. But in July he made his first essay in diplomacy. Genoa was among the earliest of the many feeble neutral states which suffered in the conflict of the Revolution with the great powers, and at the expense of which the revolutionary empire was founded. Bonaparte was sent by the younger Robespierre to remonstrate with the Genoese Government upon the use which they suffered the Coalition to make of their neutral territory. He was in Genoa from July 16 to July 23; he urged the French claim with success; he returned to Nice on July 28. But July 28, 1794, is the 9th Thermidor, on which Bonaparte's patron perished with his elder brother on the scaffold.

- ion the ke- res.

Probably the connexion of Bonaparte with the Robespierres was closer than Bonaparte himself at a later time liked to have it thought. "He was their man, their plan-maker," writes Salicetti; "he had acquired an ascendency over the Representatives (*i.e.*, especially Robespierre junior) which it is impossible to describe," writes Marmont. Accordingly after Thermidor the Representatives in Mission who remained with the army of Italy, viz., Salicetti, Albitte, and Laporte, suspended Bonaparte from his functions, and placed him provisionally under arrest (August 6). He was imprisoned at the Fort Carré near Antibes, but fortunately for him was not sent to Paris. On the 20th he was set provisionally at liberty on the ground of "the possible utility of the military and local knowledge of the said Bonaparte."

His escape was due, according to Marmont, to Salicetti's favour and to the powerful help he himself succeeded in procuring; "he moved heaven and earth." His power of attaching followers also now begins to appear; Junot and Marmont, who had become acquainted with him at Toulon, were prepared, if he had been sent to Paris, to set him free by killing the *gens d'armes* and carrying him into the Genoese territory. Marmont has graphically described the influence exerted upon himself at this time by Bonaparte; "there was so much future in his mind," he writes.

This was a passing check; early in 1795 he suffered a greater misfortune. He had been engaged in a maritime expedition of which the object was to recover Corsica, now completely in the power of the English. On March 3d he embarked with his brother Louis, Marmont, and others on the brig "Amitié." On the 11th the fleet set sail. It fell in with the English, lost two ships, and returned defeated. The enterprise was abandoned, and by the end of the same month we find Lacombe Saint Michel, member of the Committee of Public Safety, sending orders to the general of brigade Bonaparte to proceed immediately to the army of the west in order to take command of the artillery there. He left Marseilles for Paris on May 5, feeling that all the ground gained by his activity at Toulon, and by the admiration he had begun to inspire, was lost again, that his career was all to recommence, and in peculiarly unfavourable circumstances. Ordered to the army of the west

This is the last ill turn he ever received from fortune. It has been attributed to the Girondist spite of a certain Aubry against the Montagnard Bonaparte. The truth seems rather to be that the Committee of Public Safety felt that the Corsican element was too strong in the army of Italy; they remarked that "the patriotism of these refugees is less manifest than their disposition to enrich themselves." Lacombe Saint Michel knew Corsica; and the new general of the army of Italy, Schérer, remarks of Bonaparte just at this moment that "he is a really good artillerist, but has rather too much ambition and intrigue for his advancement."

The anecdote told by Bonaparte himself of his ordering an attack of outposts in order to treat a lady to a sight of real war, "how the French were successful, but necessarily no result could come out of it, the attack being a pure fancy, and yet some men were left on the field," belongs to the last months of his service in the army of Italy. It is worthy of notice, as showing his cynical insensibility, that he acted thus almost at the very beginning of his military career, and not when he had been hardened by long familiarity with bloodshed. On his arrival at Paris he avoids proceeding to the army of the west, and after a time obtains from Doulcet de Pontécoulant a post in the topographical section of the war office. Here he has an opportunity of resuming his old work, and we find him furnishing Doulcet, as he had before furnished Robespierre junior, with strategical plans for the conduct of the war in Italy. Late in August he applies for a commission from Government to go to Constantinople at the head of a party of artillerists in order to reform that department of the Turkish service. He sends in a testimonial from Doulcet which describes him as "a citizen who may be usefully employed whether in the artillery or in any other arm, and even in the department of foreign affairs." But at this moment occurs the crisis of his life. It coincides with a remarkable crisis in the history of France. Remains in Paris

The Second Revolution (1792) had destroyed the monarchy, but a republic, properly speaking, had not yet been established. Between 1792 and 1795 the government had been provisionally in the hands of the National Convention, which had been summoned, not to govern, but to create a new constitution. Now at length, the danger from foreign enemies having been averted, the Convention could proceed to its proper work of establishing a definite republic.

But there was danger lest the country, when appealed to, should elect to undo the work of 1792 by recalling the Bourbons, or at least should avenge on the Mountain the atrocities of the Terror. To preserve the continuity of government an expedient was adopted. As under the new constitution the assemblies were to be renewed periodically to the extent only of one-third at a time, it was decreed that the existing Convention should be treated as the first Corps Législatif under the new system. Thus, instead of being dissolved and making way for new assemblies, it was to form the nucleus of the new legislature, and to be renewed only to the extent of one-third. This additional law, which was promulgated along with the new constitution, excited a rebellion in Paris. The sections (or wards) called into existence a revolutionary assembly, which met at the Odéon. This the Convention suppressed by military force, and the discontent of the individual sections was thereby increased. At the same time their confidence was

heightened by a check they inflicted upon General Menou, who, in attempting to disarm the section Lepelletier, was imprisoned in the Rue Vivienne, and could only extricate himself by concluding a sort of capitulation with the insurgents. Thereupon the Convention, alarmed, put Menou under arrest, and gave the command of the armed force of Paris and of the army of the interior to Barras, a leading politician of the day, who had acquired a sort of military reputation by having held several times the post of Representative in Mission. Barras knew the army of Italy and the services which Bonaparte had rendered at Toulon, and nominated him second in command.

ions.

It does not seem that Bonaparte showed any remarkable firmness of character or originality of genius in meeting the revolt of the sections on the next day (Vendémiaire 13, *i.e.*, 5th October) with grape shot. The disgrace of Menou was a warning that the Convention required decisive action, and the invidiousness of the act fell upon Barras, not upon Bonaparte. Indeed in the official report drawn by Bonaparte himself his own name scarcely appears; instead of assuming courageously the responsibility of the deed, he took great pains to shirk it. He appeared in the matter merely as the instrument, as the skilful artillerist, by whom Barras and the Convention carried their resolute policy into effect. It will be observed that on this occasion he defends the cause of Jacobinism. This does not require to be explained, as at a later time he took much pains to explain it, by the condiseration that, odious as Jacobinism was, on this particular occasion it was identified with "the great truths of our Revolution." Bonaparte at this period appears uniformly as a Jacobin. He was at the moment an official in the Jacobin Government, and speaks in his letters of the party of the sections just as a Government official might be expected to do.

In this affair he produced an impression of real military capacity among the leading men of France, and placed Barras himself under a personal obligation. He was rewarded by being appointed in succession to Barras, who now resigned, commander of the army of the interior. In this position, political and military at the same time, he preluded to the part reserved for him later of First Consul and Emperor. He also strengthened his new position

riage.

materially by his marriage with Josephine de Beauharnais, née Tascher. The Bonaparte legend tells of a youth calling upon him to claim the sword of his father, guillotined in the Terror, of Bonaparte treating the youth kindly, of his mother paying a visit of thanks to the general, of an attachment following. But even if Bonaparte was really attached to Josephine, we must not think of the match as one of mere unworldly affection. It was scarcely less splendid for the young general Bonaparte than his second match was for the emperor Napoleon. Josephine was prominent in Parisian society, and for the lonely Corsican, so completely without connexions in Paris, or even in France, such an alliance was of priceless value. She had not much either of character or intellect, but real sweetness of disposition. Her personal charm was not so much that of beauty as of grace, social tact, and taste in dress. The act of marriage is dated Ventose 19, year IV. (*i.e.*, 9th March 1796). On this day Bonaparte had already been appointed to the command of the army of Italy. His great European career now begins.

taly.

The fourth year of the Revolutionary War was opening. The peculiar characteristic of that war is that, having been for France, at the commencement, a national war of liberation on the grandest scale, it changed its character after two years and became an equally unprecedented national war of conquest. The conquest of Austrian Flanders had been made in 1794, that of Holland in the winter of the same year. The whole left bank of the Rhine was in French occupation, and the war had passed over to the right bank. The question was no longer of the principles of the Revolution, but only of inducing the emperor and the Germanic body to conclude treaties in which Belgium and the left bank should be ceded. It was a war for territory similar to so many wars of the 18th century, but exceeding all of them in the energy with which it was conducted and the extent which it covered. Never had the warlike spirit been so predominant before in Europe. Bonaparte did not introduce, but found already introduced, the principle of conquest.

Prussia, with most of the North-German princes and Spain, had retired from the war early in 1795. Austria was now the great enemy of France by land. Accordingly the direct struggle was waged chiefly on the upper Rhine, where Austria had then extensive territories. But Austria could also be attacked on the side of Italy, where she possessed the duchy of Milan. On this side, however, a less important belligerent intervened, viz., Sardinia. It was natural to suppose that Sardinia, which since 1792 had lost Savoy and Nice, which since the military regeneration of France could not expect victory, and which had been in the habit of regarding Austria rather as a rival than as a friend, would gladly be quit of the war. Could she but be pushed aside, Austria might be attacked on the plains of Lombardy. Bonaparte had nursed this idea ever since he had been connected with the army of Italy; since Vendémiaire he had discussed it with Carnot, and it was Carnot, now one of the five Directors, who, as he himself tells us, procured Bonaparte's appointment to the Italian command.

But not only Austria could be attacked in Italy. The French Revolution, by undertaking a sort of crusade against monarchy, had furnished itself with a justification for attacking almost all states alike, for almost all were either monarchical or at least aristocratic. Italy was full of small states which could be attacked as Mainz or Holland had been attacked before. Tuscany had an Austrian prince; Rome was the patron of the *prêtres insermentés*; Venice was aristocratic. Bonaparte instinctively saw that he had a charter for indiscriminate conquest and plunder. He announced this to the army without the least disguise: "Soldiers, you are naked and ill fed; I will lead you into the most fruitful plains in the world. Rich provinces, great cities will be in your power. There you will find honour and fame and wealth!" In this announcement is the key to the history of Europe for the next twenty years.

This order of the day was issued from Nice, where Bonaparte had arrived on March 27th. The campaign began on April 10th. This, the first of Bonaparte's campaigns, has been compared to his last. As in 1815 he tried to separate Blücher and Wellington, hoping to overcome them in turn, so now with more success he attacked first the Austrians under Beaulieu and then the Sardinians under Colli. Defeating the Austrians at Montenotte, Millesimo, and Dego, he turned on the 15th against Colli, defeated him at Ceva, then at Mondovi, and concluded the convention of Cherasco on the 28th. By this convention, which was soon after turned into a treaty of peace, Sardinia was severed from the Coalition, and her principal fortresses put into the hands of France. What Bonaparte had so long dreamed of he accomplished in a single month, and turned himself at once to the conquest of Lombardy.

It
ca

The month of May was devoted to the invasion. On the 7th he crossed the Po at Piacenza, stormed the bridge over the Adda at Lodi on the 11th, and, as the archduke who governed Lombardy had quitted Milan on the 9th, retiring by Bergamo into Germany, Bonaparte entered

Milan on the 15th. That day Bonaparte told Marmont that his success hitherto was nothing to what was reserved for him. "In our days," he added, "no one has conceived anything great; it falls to me to give the example." June was spent in consolidating the conquest of Lombardy, in spoiling the country, and repressing the insurrections which broke out among the Italians, astonished to find themselves plundered by their "liberators." From the middle of July the war, as far as Austria is concerned, becomes a war for Mantua. Austria makes desperate and repeated efforts to raise the siege of this all-important fortress. On July 29 arrived Wurmser at the head of 55,000 men, making his way through Tyrol from the Rhine. He advanced on both sides of the Lake of Garda and threatened Bonaparte's communications by occupying Brescia. Bonaparte abandoned the siege of Mantua, and brought his whole force to meet the enemy. On this one occasion we find the young commander's resource and courage failing him. He called councils of war and declared in favour of retreating across the Po. When Augereau resisted this determination, he left the room declaring that he would have nothing to do with the matter, and, when Augereau asked who was to give orders, answered "You!" The desperate course was rewarded with success. The Austrians were defeated at Castiglione on August 5th, and retired into Tyrol. But Mantua had been revictualled, and Bonaparte had suffered the loss of his siege-train.

Early in September Bonaparte, having received reinforcements from France, assumed the offensive against Wurmser, and after defeating him at Bassano forced him to throw himself with the remainder of his army into Mantua (September 13).

At the end of October Austria had assembled a new army of 50,000 men, mostly, however, raw recruits. They were placed under the command of Alvinzi. Bonaparte was to be overwhelmed between this army and that of Wurmser issuing from Mantua. But by a night march he fell upon Alvinzi's rear at Arcola. The struggle lasted through three days, during which Bonaparte's life was at one moment in great danger, and ended in a complete victory for the French (November 15–17). From Arcola he used ever afterwards to date his profound confidence in his own fortune. Mantua, however, still held out, and early in January (1797) a fourth and last attempt was made by Alvinzi to relieve it, but he was again completely defeated at Rivoli, and a whole Austrian *corps d'armée* under Provera laid down its arms at Roverbella (January 16). On receiving the intelligence of this disaster Wurmser concluded the capitulation by which the French were put in possession of Mantua.

Such was the campaign of Bonaparte against Austria, by which he raised his reputation at once above that of all the other generals of the republic, Jourdan, Moreau, or Hoche. But he had acted by no means merely as a general of the republic against Austria. He had assumed from the beginning the part of an independent conqueror, neither bound by the orders of his Government nor by any rules of international law or morality.

Acts as independent conqueror.

The commander of a victorious army wields a force which only a Government long and firmly established can hold in check. A new Government, such as the Directory in France, having no root in the country, is powerless before a young victor such as Bonaparte. The danger had been early perceived: Hoche had been pronounced dangerous by Robespierre; it became imminent when Bonaparte with his unrestrained ambition pushed before the other generals. The *coup d'état* of Brumaire was in Bonaparte's mind before he had been many weeks at the head of the army of Italy. But long before he ventured to strike the existing Government we see that he has completely emancipated himself from it, and that his acts are those of an independent ruler, as had been those of Caesar in Gaul or of Pompey in the East while the Roman republic was still nominally standing. As early as June 1796 he said to Miot, "The commissioners of the Directory have no concern with my policy; I do what I please."

From the outset it had been contemplated to make the invasion of Italy financially profitable. Contributions were levied so rapaciously that in the duchy of Milan, where the French had professed to appear as brothers and liberators, a rebellion against them speedily broke out, which Bonaparte suppressed with the merciless cruelty he always showed in such cases. He kept the promise of his first proclamation: he made the army rich. "From this moment," writes Marmont, "the chief part of the pay and salaries was paid in coin. This led to a great change in the situation of the officers, and to a certain extent in their manners. The army of Italy was at that time the only one which had escaped from the unprecedented misery which all the armies had so long endured." The amount of confiscation seems to have been enormous. Besides direct contributions levied in the conquered territory, the domains of dispossessed Governments, the revenues and property of churches and hospitals, were at Bonaparte's disposal. There seems reason to think that but a small proportion of this plunder was ever accounted for. It went to the army chest, over which Bonaparte retained the control, and the pains that he took to corrupt his officers is attested in the narrative of Marmont, who relates that Bonaparte once caused a large sum to pass through his hands, and when he took great pains to render a full account of it, as the officers had then *si peu de délicatesse*, Bonaparte blamed him for not having kept it for himself.

Levying of contributions.

As he made himself financially independent of the Government, so he began to develop an independent policy. Hitherto he has had no politics, but has been content to talk the Jacobinism of the ruling party; now he takes a line, and it is not quite that of the Government. He had already, in June 1796, invaded the papal territory, and concluded a convention at Bologna by which he extorted 15 millions from the pope; immediately after the fall of Mantua he entered the States of the Church again, and concluded the treaty of Tolentino on February 19. We see how freely he combines diplomacy with war; he writes without disguise to the Directory, October 8, "You incur the greatest risk whenever your general in Italy is not the centre of everything." But now in dealing with the pope he separates his policy from that of the Directory. He demands indeed the cession of Bologna, Ferrara, and the Romagna, besides Avignon and the Venaissin, and the temporary cession of Ancona. But he recognizes the pope by treating with him, and towards the Catholic religion and the priesthood he shows himself unexpectedly merciful. Religion is not to be altered in the ceded Legations, and Bonaparte extends his protection in the most ostentatious manner to the *prêtres insermentés*, whom he found in large numbers in the States of the Church. This was the more marked as they were at this time objects of the bitterest persecution in France. Here is the first indication of the policy of the Concordat, but it is also a mark of Bonaparte's independent position, the position rather of a prince than of a responsible official; nay, it marks a deliberate intention to set himself up as a rival of the Government. His manner of conducting the war was as unprecedented as his relation to the Government, and in like manner foreshadowed the Napoleonic period. It was not that of a civilized belligerent, but of a universal conqueror. The Revolution had put all international law into abeyance. Bonaparte in Italy, as in his later wars, knew

His Italian policy.

nothing of neutrality. Thus Tuscany, the first of all states to conclude a treaty with the French republic, is not thereby saved from invasion. Bonaparte's troops march in, seize Leghorn, and take possession of all the English property found in that port. More remarkable still is the treatment of Venice. The territory of the republic is turned unceremoniously into a field of battle between France and Austria, and at the end of the war the Venetian republic is blotted out of the map.

Further is to be remarked the curious development which was given to the principle of plunder. The financial distress of France and the impoverishment of the army at the opening of the campaign might account for much simple spoliation. But Bonaparte introduced the practice of transferring pictures and statues from the Italian palaces and galleries to France. This singular revival of primitive barbaric modes of making war becomes more striking when we reflect that the spoiler of Italy was himself an Italian.

Altogether these campaigns brought to light a personality entirely without precedent in modern European history. True, the Revolution behind him and the circumstances around him were absolutely unprecedented. Marmont remarked at the time the rapid and continual development which just then showed itself in Bonaparte's character. "Every day," he writes, "he seemed to see before him a new horizon." An ambitious man had suddenly become aware that a career entirely unparalleled was open to him, if only he could find audacity and unscrupulous energy to enter upon it. Add to this that he had lived for three years in the midst of disorders and horrors such as might well have dissipated all principles, beliefs, and restraints. Even as early as the 13th Vendémiaire we find him impressed with a fatalist belief in his own luck ("I received no hurt; I am always lucky," he writes), and there are indications that his wonderful escape at Arcola greatly heightened this belief in a mind naturally somewhat superstitious.

At this moment, as Bonaparte's private political views begin to appear, his Jacobinism, even his republicanism, slips from him like a robe. As early as May 1797 he said to Miot and Melzi, "Do you suppose that I triumph in Italy for the glory of the lawyers of the Directory, a Carnot or a Barras? Do you suppose I mean to found a republic? What an idea! a republic of thirty millions of people! with our morals, our vices! how is such a thing possible? The nation wants a chief, a chief covered with glory, not theories of government, phrases, ideological essays that the French do not understand. They want some playthings; that will be enough; they will play with

war of conquest. The conquest lled to the command of
been made in 1794, that of Ho these were thoroughly
same year. The whole left ba him from the line of

the Tagliamento, then from that of the Isonzo, and advanced steadily until he reached Leoben in Styria on April 7th. Here began negotiations.

There has been much misconception of the preliminaries Pr
of Leoben, because Bonaparte's position and objects have aric
not been properly understood. We expect to find these Le
preliminaries containing conditions most triumphant for France, since they were won by an invasion which stopped little short of Vienna, and followed a series of victories most ruinous to the Austrian military power. But it was not France that imposed these conditions, it was Bonaparte, whose interest was not by any means identical with that of France. His object was not so much to vanquish Austria as to eclipse the French generals on the Rhine and wrest from them the honour of concluding the war. In order to do this it was necessary to surprise Austria by his moderation, and this he did in the preliminaries of Leoben. The object of the war on the part of France had long been to obtain definitive possession of Belgium and the Rhine frontier; this might now have been obtained at the expense of Bonaparte's Italian conquests. At Leoben, however, no such arrangement was made. Belgium indeed, so far as it belonged to Austria, was ceded, and the emperor agreed to "recognize the limits of France as decreed by the laws of the republic." This expression afterwards was made to seem ambiguous, but at the time it appears to have been understood to refer almost exclusively to the Belgian territories, which had been organized by the French into nine departments. It seems certainly not to have included that large territory limited by the Rhine which it was not competent to Austria to cede, since in the main it did not belong to Austria but to the Germanic empire. But what was to become of Bonaparte's conquests in Lombardy? Here we meet with a principle of action which, though not invented by him, was mainly instrumental in founding his empire. An independent republic was to be set up in Lombardy, and for this Austria was to receive as an indemnity the continental possessions of the Venetian republic as far as the Oglio, with Istria and Dalmatia. But how came this territory to be at the disposal of Bonaparte, since the Venetian republic was a neutral state? The answer is that its neutrality had been utterly disregarded by Bonaparte during the war, and that, as its territory had been freely trampled on by his troops, irritation had necessarily arisen among the Venetians, thence quarrels with the French, thence on the side of the French an attack on the aristocratic government and the setting up of a democracy. Of all this the result was now found to be that the Venetian empire was a conquered territory, which in her next treaty France could cede in exchange for any desired advantage. This had been the principle of the partition of Poland; it was now to be the principle of a universal conquest.

The summer of 1797 was passed by Bonaparte at Montebello near Milan. Here he rehearsed in Italy the part of emperor, formed his court, and accustomed himself to all the functions of government. He was chiefly engaged at this time in accomplishing the dissolution of the Venetian republic. He had begun early in the spring by provoking insurrections in Brescia and Bergamo. In April the insolence of a French officer provoked a rising against the French at Salò, for which Junot, sent by Bonaparte, demanded satisfaction of the senate on the 15th. The French now attempted to disarm all the Venetian garrisons that remained on the *terra firma*, and this led to a rising at Verona in which some hundreds of Frenchmen were massacred (April 17th). On the 19th a French Occ
sea-captain, violating the customs of the port at the tion
Lido, was fired upon from a Venetian fort. Bonaparte Ven
now declared that he would be a new Attila to Venice,

and issued a declaration of war. The feeble Government could only submit. A revolution took place at Venice, and French troops took possession of the town on May 16th. A treaty was now concluded by Bonaparte "establishing peace and friendship between the French republic and the republic of Venice," and providing that "the French occupation should cease as soon as the new Government should declare that it no longer needed foreign assistance." "A principal object of this treaty," as Bonaparte candidly explained to the Directory, "was to obtain possession without hindrance of the city, the arsenal, and everything." At the time that he was thus establishing friendship he was, as we know, ceding the territory of Venice, including at last the town, to Austria.

When we read the letters written by him at this period we see that already, only a year after he assumed for the first time the command of an army, he has fully conceived the utmost of what he afterwards realized. Had he been shown in vision at this time what he was to be at his zenith in 1812, when he was the astonishment and terror of the world, he would probably have said that it fell short of his expectations.

One concession he had made in order to prevent Hoche and Moreau from sharing his laurels; at Leoben he had granted good terms to Austria. But the definitive treaty was not yet concluded, and it was still possible to withdraw this concession. This was the more possible as Austria might now be threatened with an attack from Bonaparte and Hoche at the same time. By virtue of the new principle she might also be bribed. The town of Venice might be ceded to her as well as the province, and in return for the left bank of the Rhine indemnity might be granted to her within the Germanic empire. The principle of ceding what is not one's own is evidently capable of wide application. But Austria had still one hope, for it seemed impossible that France herself could suffer Bonaparte to run his headlong career without interference, especially as she now had popular assemblies. The difficulty which Bonaparte had dissipated by his cannon in Vendémiaire had returned, as it could not fail to do. A Jacobinical regicide republic had to support itself in the midst of a nation which was by no means Jacobinical, and which had representative assemblies. These assemblies, renewed by a third for the second time in the spring of 1797, placed Pichegru, suspected of royalism, in the chair of the Five Hundred, and Europe began to ask whether the restoration of the Bourbons was about to follow. Bonaparte at Montebello found that the Austrian negotiators were bent upon delay.

The rising party was not perhaps mainly royalist; its most conspicuous representative, Carnot, the Director, was himself a regicide. In the main it aimed only at respectable government and peace, but a minority were open to some suspicion of royalism. This suspicion was fatal to the whole party, since royalism had at this time been thoroughly discredited by the follies of the *émigrés*. An outcry is raised by the soldiers. We can measure the steady progress which had been made by the military power since Vendémiaire; it had then been an instrument in the hands of the Government, now it gives the law and makes the Government its instrument. The armies of the Rhine, represented by Hoche, oppose the new movement; as to Bonaparte, he was driven into opposition by self-defence. Dumolard, a deputy, had called attention to his monstrous treatment of the Venetian republic; he anticipated the judgment of history by comparing it to the partition of Poland. Bonaparte had already divulged to a friend the secret that he despised republicanism, but this attack made him once more, for the last time, a republican and a Jacobin. It is, however, probable that he would in any case have sided with the majority of the Directory, since anything which favoured the Bourbons was a hindrance to his ambition. And thus the armies of the republic stood united against the tendency of public opinion at home. Imperialism stood opposed to parliamentary government, believing itself—such was the bewilderment of the time—to be more in favour of the sovereignty of the people than the people itself, and not aware that it was paving the way for a military despot.

Coup d'état of Fructidor. The catastrophe came on 18th Fructidor (September 4, 1797), when Augereau, one of Bonaparte's generals of division, who had been sent by Bonaparte to Paris, surrounded the Corps Législatif with twelve thousand men and arrested the most obnoxious representatives, while another force marched to the Luxembourg, arrested the Director Barthélemi, and would have arrested Carnot had he not received warning in time to make his escape. This stroke was followed by an outrageous proscription of the new party, of whom a large number, consisting partly of members of the Councils, partly of journalists, were transported to die at Cayenne, and the elections were annulled in forty-eight departments.

Such was Fructidor, which may be considered as the third of the revolutions which compose the complex event usually known as the French Revolution. In 1789 the absolute monarchy had given place to a constitutional monarchy, which was definitively established in 1791. In 1792 the constitutional monarchy fell, giving place to a republic which was definitively established in 1795. Since 1795 it had been understood that revolution was over, and that France was living under a constitution. But in Fructidor this constitution also fell, and government became revolutionary again. It was evident that a third constitution must be established; it was evident also that this constitution must set up a military form of government,—that is, an imperialism; but two more years passed before this was done.

The benefit of the change was reaped in the end by Bonaparte. Naturally he favoured it and took a great share in contriving it. But it seems an exaggeration to represent him as the exclusive or even the principal author of Fructidor. Hoche took the same side as Bonaparte; Augereau outran him (and yet Augereau at this time was by no means a mere echo of Bonaparte); the division of the army of Italy commanded by Bernadotte, which had been recently detached from the army of Sambre-et-Meuse, and stood somewhat aloof from Bonaparte's influence, sided with him in this instance. The truth is that the rising party of Moderates gave offence to the whole military world by making peace their watchword. Outside the armies too there was profound alarm in the whole republican party, so that the circle of Madame de Staël was strongly Fructidorian, and this certainly was not guided by the influence of Bonaparte, though at this time Madame de Staël was among his warmest admirers. When the blow had been struck, Bonaparte knew how to reap the utmost advantage from it, and to exhibit it in its true light as mortal at the same time to the Moderates and to the republican Government itself, which now ceased to be legal and became once more revolutionary, and as favourable only to the military power and to the rising imperialism. He congratulated the armies on the fall of "the enemies of the soldier and especially of the army of Italy," but accorded only the faintest approval to the Directory.

The death of Hoche, occurring soon after, removed from Bonaparte's path his only rival in the affections of the already omnipotent soldiery. Hoche alone among the generals beside Bonaparte had shown political talents:

had he lived longer, he might have played with success the part in which Moreau afterwards failed.

The revolution of Fructidor, being military, had an immediate effect on foreign affairs. It commences the period which was to last till the fall of Napoleon, a period of war pursued by France for its own sake, and as a kind of national business. As negotiations with England are at once violently broken off, so a change comes over the negotiations with Austria. With the fall of the peace party Austria loses all hope of favourable terms. Bonaparte is now residing at Passeriano in a villa belonging to Doge Manin, and the negotiations take place at Udine in the neighbourhood. As at Leoben, Bonaparte is more pacific than the Directory. They are prepared to recommence the war; his ambition is to win from the other generals the distinction of terminating it. The struggle between them concerns the fate of Venice, the complete possession of which is a bribe sufficient to induce Austria to recede entirely from the preliminaries of Leoben, but which the Directory is unwilling to cede. Between the beginning of September and the middle of October this struggle continued; at length, on October 17th, the treaty was signed at the little village of Campo Formio (more correctly Campo Formido) close to Udine. Bonaparte took his own course, gave Venice, Istria, Dalmatia, and all Venetian territory beyond the Adige to Austria, founded the Cisalpine Republic, and reserved for France, besides Belgium, Corfu and the Ionian Islands. A congress was to open at Rastatt, and Austria bound herself by a secret article to do her best to procure for France from the Germanic body the left bank of the Rhine. By retaining the Ionian Islands Bonaparte gave the first intimation of his design of opening the Eastern question.

aty of apo mio.

He now left Italy, setting out from Milan on November 17th, made a flying visit to Rastatt, where the congress had already assembled, and reached Paris on December 5th. What next would be attempted by the man who at twenty-seven had conquered Italy and brought to an end the most memorable Continental war of modern times? From a speech delivered by him on the occasion of his reception by the Directory it appears that he had two thoughts in his mind,—to make a revolution in France ("when the happiness of the French people shall be based on the best [or on better] organic laws, all Europe will be free") and to emancipate Greece ("the two most beautiful parts of Europe, once so illustrious for arts, sciences, and the great men of whom they were the cradle, see with the loftiest hopes the genius of liberty issue from the tombs of their ancestors"). He had now some months in which to arrange the execution of these plans. The Directory, seeing no safety but in giving him employment, now committed the war with England to his charge. He becomes "général en-chef de l'armée d'Angleterre." His study of internal politics soon landed him in perplexity. Should he become a Director, procuring an exemption from the rule which required the Directors to be more than forty years of age? He could decide on nothing, but felt himself unprepared to mingle in French party strife. He decided therefore that "the pear was not ripe," and turned again to the military schemes which might raise his renown still higher during the year or two which the Directory would require to ruin itself. It seemed possible to combine war against England with the Oriental plan which had been suggested to him, it is said, by Monge at Passeriano. During the last war between Russia and Turkey some publicists (including Volney, an acquaintance of Bonaparte's) had recommended France to abandon her ancient alliance with Turkey and seek rather to share with Russia in her spoils. Thus was suggested to Bonaparte in Italy the thought of seizing Greece. Now as head of the army of England he fixed his eyes on Egypt also. In India the game was not yet quite lost for France, but England had now seized the Cape of Good Hope. To save therefore what remained of her establishments in India, France must seize Egypt. She must not only conquer but colonize it ("if forty or fifty thousand European families fixed their industries, their laws, and their administration in Egypt, India would be presently lost to the English much more even by the force of events than by that of arms"). Such was the scheme, according to which Turkey was to be partitioned in the course of a war with England, as Venice had disappeared in the course of a war with Austria.

turns Paris.

Egyptian expedition.

That such a scheme could scarcely fail to kindle a new European war more universal than that which Bonaparte had just brought to a close was probably its principal recommendation in his eyes. He also instinctively saw that, while he conquered in the East, France, deprived of her best troops and generals, would suffer disasters at home, though he could not anticipate what actually happened—that she would be unfortunate both at home and in the East. But the European war showed signs of recommencing even before he could set sail. For the tide of militarism in France could not be arrested for a moment; scarcely a month passed but was marked by some new aggression and annexation. In the spring of 1798 the old constitution of Switzerland was overthrown, French troops entered Bern and seized a treasure of 40,000,000 francs; at the same time a quarrel was picked with the Papal Government; it was overthrown, the treasury plundered, and the aged pope, Pius VI., carried into captivity. Thus, as Berthier said, money was furnished for the Egyptian campaign; but on the other hand Europe was thoroughly roused; England could meet the threatened attack by forming a new Coalition, and at the beginning of May, three weeks before Bonaparte set sail, the probability of a new Continental war was already so great that he writes, for the benefit of General Brune, a plan for defending Italy against an attack by a superior force of Austrians. It is asserted by Miot that at the last moment Bonaparte would gladly have abandoned his Eastern expedition, since it would have suited him as well to take the command again against Austria, but that the Directory, to be rid of him at all hazards, forced him to depart.

In any case the departure of Bonaparte for the East with 30,000 men and Generals Murat, Berthier, Desaix, Kléber, Lannes, and Marmont—Nelson in front of him and a European war behind—perhaps marks the moment of wildest confusion in the modern history of Europe. From his letters written on board "L'Orient" it would seem that he scarcely realized the terrible risk he ran; it is to be considered that the superiority of the English marine had not yet been clearly proved, and that the name of Nelson was not yet redoubtable. He set sail on May 19, having stimulated the zeal of his soldiers by promising that each should return rich enough to buy six "arpents" of land (the Directory were obliged to deny the genuineness of the proclamation), and, eluding Nelson, who had been driven by a storm to the island of St Pietro near Sardinia, arrived on June 9 at Malta, where a squadron from Civita Vecchia and another from Ajaccio had preceded him. This island was in the possession of the Knights of St John of Jerusalem, who acknowledged the king of Naples as their feudal superior and the czar as their protector. To attack them was the direct way to involve France in war both with Naples and Russia. Bonaparte, demanding admission into the harbour for his fleet, and receiving answer that the treaties which guaranteed the neutrality of Malta permitted only the admission of four ships, attacked at once, as indeed he had been expressly com-

manded by the Directory to do (*Nap. Corr.*, iv. 53). The people rose against the knights; the grand master Hompesch opened negotiations, and on the 12th Bonaparte entered La Valette. He is enthusiastic about the strength and importance of the position thus won. "It is the strongest place in Europe; those who would dislodge us must pay dear." He spent some days in organizing a new Government for the island, and set sail again on the 19th. On July 2 he issues his first order in Alexandria.

During the passage we find him prosecuting his earlier scheme of the emancipation of Greece. Thus from Malta he sends Lavalette with a letter to Ali Pasha of Janina. His plan therefore seems to embrace Greece and Egypt at once, and thus to take for granted the command of the sea, almost as if no English fleet existed. The miscalculation was soon made manifest. Bonaparte himself, after occupying Alexandria, set out again on the 8th and marched on Cairo; he defeated the Mamelukes first at Chebreiss and then at Embabeh within sight of the Pyramids, where the enemy lost 2000 and the French about 20 or 30 killed and 120 wounded. He is in Cairo on the 24th, where for the most part he remains till January of 1799. But a week after his arrival in Cairo the fleet which had brought him from France, with its admiral Brueys, was destroyed by Nelson in Aboukir Bay. For the first time, in reporting this event to the Directory, it seems to flash on Bonaparte's mind that the English are masters of the sea. The grand design is ruined by this single stroke. France is left at war with almost all Europe, and with Turkey also (for Bonaparte's hope of deceiving the sultan by representing himself as asserting his cause against the Mamelukes was frustrated), and her best generals with a fine army are imprisoned in another continent.

...asion Syria.

It might still be possible to create a revolution in Turkey in Asia, if not in Turkey in Europe. The Turks were preparing an army in Syria, and in February 1799 Bonaparte anticipated their attack by invading Syria with about 12,000 men. He took El Arish on the 20th, then Gaza, and arrived at Jaffa on March 3. It was taken by assault, and a massacre commenced which, unfortunately for Bonaparte's reputation, was stopped by some officers. The consequence was that upwards of 2000 prisoners were taken. Bonaparte, unwilling either to spare food for them or to let them go, ordered the adjutant-general to take them to the sea-shore and there shoot them, taking precautions to prevent any from escaping. This was done. "Now," writes Bonaparte, "there remains St Jean D'Acre." This fortress was the seat of the pasha, Jezzar. It is on the sea-shore, and accordingly England could intervene. Admiral Sir Sidney Smith, commanding a squadron on the coast, opened fire on the French as they approached the shore, and was surprised to find his fire answered only by musketry. In a moment he divined that the siege artillery was to come from Alexandria by sea, and very speedily he discovered the ships that carried it and took possession of them. On March 19 Bonaparte is before Acre, but the place receives supplies from the sea, and support from the English ships, while his artillery is lost. He is detained there for two whole months, and retires at last without success. This check, he said, changed the destiny of the world, for he calculated that the fall of Jezzar would have been followed by the adhesion of all the subject tribes, Druses and Christians, which would have given him an army ready for the conquest of Asia.

The failure had been partially redeemed by a victory won in April over an army which had marched from the interior to the relief of Acre under Abdallah Pasha, and which Bonaparte defeated on the plain of Esdraelon (the battle is usually named from Mount Tabor). In the middle of May the retreat began, a counterpart on a small scale of the retreat from Moscow, heat and pestilence taking the place of frost and the Cossacks. On the 24th he is again at Jaffa, from which he writes his report to the Directory explaining that he had deliberately abstained from entering Acre because of the plague which, as he heard, was ravaging the city. On June 14 his letters are again dated from Cairo. His second stay in Egypt lasts two months, which were spent partly in hunting the dethroned chief of the Mamelukes, Murad Bey, partly in meeting a new Turkish army, which arrived in July in the Bay of Aboukir. He inflicted on it an annihilating defeat near its landing-place; according to his own account ten or twelve thousand persons were drowned. This victory masked the final failure of the expedition. It was a failure such as would have ruined Bonaparte in a state enjoying publicity, where the responsibility could have been brought home to him and the facts could have been discussed. For a year of warfare, for the loss of the fleet, of 6000 soldiers, and of several distinguished officers (Brueys, Caffarelli, Cretin), for disastrous defeats suffered in Europe, which might have been averted by Bonaparte and his army, for the loss for an indefinite time of the army itself, which could only return to France by permission of the English, there was nothing to show. No progress was made in conciliating the people. Bonaparte had arrived with an intention of appealing to the religious instinct of the Semitic races. He had imagined apparently that the rebellion of France against the Catholic religion might be presented to the Moslems as a victory of their faith. He had declared himself a Mussulman commissioned by the Most High to humble the cross. He had hoped at the same time to conciliate the sultan; it had been arranged that Talleyrand should go to Constantinople for the purpose. But Talleyrand remained at Paris, the sultan was not conciliated, the people were not deluded by Bonaparte's religious appeals. Rebellion after rebellion had broken out, and had been repressed with savage cruelty. It was time for him to extricate himself from so miserable a business.

It appears from the correspondence that he had promised to be back in France as early as October 1798, a fact which shows how completely all his calculations had been disappointed. Sir Sidney Smith now contrived that he should receive a packet of journals, by which he was informed of all that had passed recently in Europe and of the disasters that France had suffered. His resolution was immediately taken. On August 22 he wrote to Kléber announcing that he transferred to him the command of the expedition, and that he himself would return to Europe, taking with him Berthier, Lannes, Murat, Andréossi, Marmont, Monge, and Berthollet, and giving orders that Junot should follow in October and Desaix in November. After carefully spreading false accounts of his intentions, he set sail with two frigates in the night of the same day. He arrived after a voyage of more than six weeks, during which he revisited Corsica, in the harbour of Fréjus on October 9.

Return to France.

From this moment the tide of his fortune began to flow again. His reappearance seemed providential, and was hailed with delight throughout France. The system established in Fructidor was essentially military. It had led directly to the violent aggressions of 1798, and to a great law of military service introduced by General Jourdan, which was the basis of the Napoleonic armies; it had created a new European war. But it was evidently inconsistent with the form of government established in 1795. A Directory of civilians were not qualified to conduct a policy so systematically warlike. Hence the war of 1799 had been palpably mismanaged. The armies and the generals were there but the presiding strategist

and statesman was wanting. In Italy conquest had been pushed too far. Half the troops were locked up in fortresses or occupied in suppressing rebellions; hence Macdonald at the Trebbia and Joubert at Novi were defeated by Suwaroff, Mantua fell, and the work of Bonaparte in Italy was well-nigh undone. Government was shaken by these disasters. A kind of revolution took place in June. Four new members entered the Directory, of whom three—Gohier, Roger-Ducos, and General Moulin—represented on the whole the revival of the Jacobinism of 1793, while the fourth, Sieyès, the most important politician of this crisis, represented the desire for some new constitutional experiment. The remedy which first suggested itself was to return to the warlike fury and terrorism of 1793. The Jacobin Club revived and held its sittings in the Salle du Manége. Many leading generals, especially Jourdan and Bernadotte, favoured it. But 1793 was not to be revived. Its passions had gone to sleep, and the memory of it was a nightmare. Nevertheless a sort of Terror began. The hardship of recruitment caused rebellions, particularly in the west. Chouannerie and Royalism revived, and the odious Law of Hostages was passed to meet them. After seven years of misery France in the autumn of 1799 was perhaps more miserable than ever.

If 1793 could not be revived, what alternative? Sieyès perceived that what was needed was a supreme general to direct the war. But, though he had ceased to believe in popular institutions, and had become a convert to a new kind of aristocracy, he did not wish his supreme general to control civil affairs. He looked for an officer who should be intelligent without being too ambitious. His choice fell upon Joubert, who was nominated commander of the army of Italy that he might acquire the necessary renown. But Joubert was killed at Novi in August. From this time Sieyès had remained uncertain. Advances were made in vain to Moreau. Who can say what might have happened in a few months? Some general of abilities not very commanding would have risen to a position in which he would have controlled the fate of France. Perhaps Masséna, whose reputation at this moment reached its highest point through the victories of Zurich, but who was not made either for an emperor or for a statesman, might have come forward to play the part of Monk.

Revolution of Brumaire. Upon this perplexing gloom the reappearance of Bonaparte came like a tropical sunrise, too dazzling for Sieyès himself, who wanted a general, but a general he could control. On October 16 he arrived at his old Parisian house in the Rue de la Victoire, and on the 9th and 10th of November (Brumaire 18, 19) the revolution took place. Bonaparte had some difficulty at first in understanding the position. He found a Jacobin party clamouring for strong measures and for a vigorous prosecution of the war; at the head of this party he saw military men, particularly Jourdan and Bernadotte. As an old Robespierrist, a Fructidorian, and a soldier, he was at first attracted to this faction. Sieyès, the object of their most bitter attacks, he was at first disposed to regard as his principal enemy. Gradually he came to perceive that this time he was to rise not as a Jacobin but as the soldier of anti-Jacobinism, and that he must place his sword at the service of Sieyès. For his part Sieyès could not but perceive that Bonaparte was not precisely the war minister he sought. But by the efforts of Lucien and Joseph Bonaparte, of Roederer, and Talleyrand a coalition was at last effected between them, though Sieyès continued to predict that after the success Bonaparte would throw him off. The movement which now took place was the most respectable, the most hopeful, as for a long time it seemed the most successful, effort that had been made since 1792 to lift France out of the slough. Instead of reviving Jacobinism it was resolved to organize a strong and skilled Government. A grand party of respectability rallied round Sieyès to put down Jacobinism. Ducos among the Directors (he had been converted), the majority of the Council of Ancients, Moreau and Macdonald, the generals of purest reputation, Bonaparte and the generals personally attached to him, composed this party. On the other side the Jacobinical party consisted of the Directors Gohier and Moulin, the majority of the Council of Five Hundred, Generals Jourdan and Bernadotte. Which party would be followed by the rank and file of the army was an anxious question.

It was determined to take advantage of a provision of the constitution which had been originally inserted by the Girondists as a safeguard against aggressions from the municipality of Paris, and to cause the Council of Ancients to decree a meeting of the Councils outside Paris at the palace of St Cloud. At this meeting it was intended to propose a reform of the constitution. The proposal would be supported by a majority in the Council of Ancients, and by many, but probably not a majority, in the Council of Five Hundred. It was foreseen that the Jacobins might give trouble, and might need to be eliminated, as they had themselves eliminated the Girondins. With a view to this, when the decree was passed on November 9th, General Bonaparte, made commander of all the troops in Paris, was entrusted with the execution of it. It is carefully to be observed that he does not, like Cromwell, act of his own free will against the assembly, but is appointed by the assembly to act in its name. No one thought of destroying the republic; the question was of introducing the famous perfect constitution of Sieyès. Bonaparte appeared, surrounded by the generals of his party, in the Council of Ancients, where he skilfully evaded taking the oath to the constitution. He then reviewed the troops, and it became apparent that he could count on them. From this moment Brumaire may be said to have been decided. The next step was that Sieyès and Ducos resigned their places on the Directory; Barras was induced to follow their example; but Gohier and Moulin were firm. Gohier was placed under ward of Moreau at the Luxembourg, while Moulin made his escape. It now only remained to deal with the Council of Five Hundred, the stronghold of Jacobinism.

The revolution was consummated on the next day at St Cloud. Bonaparte and Sieyès sat in a private room while the Councils began their deliberations; but, being informed that it was proposed to renew the oath to the existing constitution, Bonaparte determined to interfere. There seems to have been mismanagement here. Sieyès, not Bonaparte, should have interfered, but probably he was rendered helpless, as often happened to him, by timidity. Bonaparte then entered the Council of Ancients, where he delivered a confused harangue which did him little good, though the assembly was well-disposed to him. His position was a false one, though he urged very justly that the existing constitution had been practically destroyed by the illegalities of Fructidor, Floréal, and Prairial. He then passed to the hostile Council of Five Hundred, where he was received with cries of *Hors la loi! A bas le dictateur!* He was seized by the collar and attempts were made to push him out of the hall.

He was now almost in despair, and no wonder! By the backwardness of Sieyès he had been pushed into the part of Cromwell. But Cromwell had soldiers devoted to him, and of theocratic rather than republican ideas; the soldiers of Bonaparte had only just been put under his command, and they were fanatical republicans. The false step must be retrieved. The soldiers must be persuaded that Bonaparte was no Cromwell, but a staunch republican,

and that they were not called upon to act against an assembly, but only against a traitorous minority, as at Fructidor. Lucien Bonaparte, who was president of the Five Hundred, performed this miracle. Bonaparte had sent grenadiers to rescue him. Lucien was at the tribune, where he was defending his brother amidst noisy interruption. At the appearance of the grenadiers he threw off his official dress and retired under their escort. In the hall he mounted on horseback and addressed the troops who were employed to guard the legislature, declaring that the council was oppressed by assassins, brigands paid by England; he charged the soldiers to deliver the majority from this oppression by clearing the hall. He brandished a sword and swore to stab his brother if ever he attacked the liberties of Frenchmen. On the clear understanding that no violence against the assembly was intended, and with the express sanction of its president, the soldiers then cleared the hall. In the evening at 9 o'clock Lucien reassembled a certain number of the members and proposed to them to nominate a committee which should report on the state of affairs. This committee was at once named, and speedily presented a report to the effect that Sieyès, Roger-Ducos, and Bonaparte should compose a provisional executive under the title of consuls, that the legislature should adjourn till February 20 (1 Ventose), a committee of twenty-five members from each Council being left to deliberate along with the consuls upon the changes to be made in the constitution; at the same time, as in Fructidor, a certain number of members (fifty-five) were to be expelled from the Councils.

Thus the original plan was on the whole carried into effect. But it had been sadly marred by the unseemly appearance of Bonaparte and by his gasconades, in which he bade the Council remember that he "marched under the escort of the god of fortune and the god of war." An attempt was made to conceal these mistakes by publishing in the *Moniteur* a garbled report of his speech.

Brumaire taken by itself is the victory of Sieyès rather than of Bonaparte. It raised Sieyès to the position he had so long coveted of legislator for France. The constitution now introduced was really in great part his work, but his work so signally altered in one point that it resulted in the absolute supremacy of Bonaparte. We should especially notice that it is Sieyès, not Bonaparte, who practically suppresses representative institutions. The long-expected scheme of Sieyès was at last promulgated, and we see with astonishment that the man of 1789, the author of *Qu'est ce que le Tiers État?* himself condemns political liberty. In this scheme the assemblies, of which there are three, the Senate, the Tribunate, and the Corps Législatif, are not chosen by popular election at all. The two latter are nominated by the Senate, and the Senate is chosen at the outset in part by the provisional consuls and in part by co-optation. The Tribunate alone had the right of public debate, which was separated from the right of voting. This latter was assigned to the Corps Législatif. These arrangements, which caused the nullity of parliamentary institutions in the Napoleonic period, were devised not by Bonaparte but by Sieyès, who confined popular election to certain lists of notability out of which the assemblies were required to be chosen. By this scheme Sieyès, who retained all his hatred for the old régime and the old noblesse, passed sentence upon the whole constructive work of the Revolution; this sentence was only ratified by Bonaparte.

But, while he absolutely condemned democracy, Sieyès did not want to set up despotism. The Senate was to be supreme; it was to be a kind of hereditary aristocracy, the depositary of the tradition of the Revolution; above it, and capable of being deposed by it, was to be a doge called Grand Elector, whose main function consisted in choosing two consuls, of whom one was to take the home and the other the foreign department. Here again Bonaparte acquiesced as far as he could. He adopted the consuls and the triple executive, even lowering apparently the grand elector of Sieyès by giving him the more republican title of First Consul. But he displayed signally and for the first time the adroitness, rapid and audacious, which was to be the characteristic of his diplomacy. He declaimed violently against the feebleness of the grand elector and the consuls in this scheme, feigning to overlook that it concentrated power intentionally in the Senate; then instead of sending back the scheme for revision he simply strengthened immensely the attributions of the first consul, leaving the other consuls and the assemblies as weak as before. By this stroke a strong aristocracy was turned into a strong despotism, and at the same time advantage was taken of the very peculiar character of Sieyès, who always when he met with opposition sank into an impenetrable silence. Bonaparte boasted afterwards that he had sealed his victory over Sieyès by a handsome bribe at the expense of the public.

The provisional consulate of Sieyès, Ducos, and Bonaparte lasted only from November 10th to December 13th. Then through the promulgation of the new constitution it made way for the definitive consulate of Bonaparte, Cambacérès, and Lebrun, which lasted four years. By the constitution of 22 Frimaire, year VIII. (which was never debated in any assembly, but, after being devised by the two legislative committees meeting at the Luxembourg under the presidency of Bonaparte, and in the presence of the other consuls, and after being redacted by Daunou, was introduced by a popular vote), Bonaparte became First Consul for ten years with a salary of half a million francs, with a sole power of nominating the council of state, the ministers, ambassadors, officers of army and fleet, and most of the judges and local officials, and with a power in nominal conjunction with the other consuls of initiating all legislation and deciding war and peace. Sieyès and Ducos retired, and under the new constitution the second and third consuls were Cambacérès, an eminent legist, and Lebrun, an old official of Louis XV.'s time. The party of Brumaire had intended to set up a republic, but this constitution created a strong monarchy under the thinnest disguise.

Bonaparte becomes First Consul.

For the moment it was much that France renounced Jacobinism and ceased to tear herself to pieces. The civil war of the west and the foreign war were alike energetically taken in hand. A proclamation to the inhabitants of the west (December 28th) breathed for the first time the spirit of tolerance, of respect for religion, and consideration for the clergy. It was a precursor of the Concordat, and attacked the civil war at its root. It was accompanied by the most imperious threats against the refractory, who are to be treated "like the Arabs of the desert," who are warned that they have to do with a man "accustomed to rigorous and energetic measures,"—an allusion apparently to the massacres of Jaffa and Cairo. This policy, accompanied by decisive military action, was speedily successful. By the end of February all was quiet in the west; Frotté, the most active leader in Normandy, had surrendered at discretion, and had been shot, though Bonaparte had expressly announced that if he surrendered he might count on the generosity of the Government. In preaching a religious peace at home Bonaparte was sincere; he was less so in announcing a policy of peace in Europe, for he well knew that he needed a victory to cover his apostasy from republicanism. Nevertheless the announcement was necessary as part of the national renunciation of Jacobinism; and it was

harmless, for the Coalition was scarcely likely to accept peace when they had the military advantage. Indeed they could not consistently do so, since they had gone to war on the ground that peace with the Directory had appeared in 1798 to be less endurable than war, and the accession of Bonaparte could not but seem to them likely to make matters worse. In thinking thus they were substantially right, as the sequel proved, but they did not sufficiently understand that Bonaparte was not now the "champion of Jacobinism," as Pitt called him, but had become its enemy and destroyer. When England and Austria refused his overtures, Bonaparte had the good fortune of getting precisely what he wanted, viz., war, in precisely the way he wished, that is, as apparently forced upon him. *This war is peculiar in the circumstance that* throughout its course Bonaparte has a military rival with whom he is afraid to break, and who keeps pace with him in achievements—Moreau. To Moreau the success of Brumaire had been mainly due, and he had perhaps thought that the new constitution, as it did not seem to contemplate the First Consul commanding an army, had removed Bonaparte from the path of his ambition. He now held the command of the principal army, that of the Rhine, in which post Bonaparte could not venture to supersede him. The problem for Bonaparte throughout the war was to prevent Moreau, and in a less degree Masséna, who was now in command of the army of Italy, from eclipsing his own military reputation. Russia had now retired from the Coalition, so that, as in 1796, Austria and England were the only belligerents. Italy had been almost entirely lost, and Masséna, at the head of the army of Italy, opposed to General Melas, was almost where Bonaparte had been before his Italian campaign began. But France had retained the control of Switzerland, and Moreau with more than 100,000 men arranged along the Rhine from the Lake of Constance to Alsace stood opposed to Kray, whose headquarters were at Donaueschingen. It seemed that the campaign would be conducted by Moreau and Masséna receiving instructions from Bonaparte at Paris. That the decisive campaign would have been in Bavaria seems so evident that the military writer Bülow conjectures that the French were afraid of alarming Europe by a too decisive victory, which would have brought them at once to the walls of Vienna, and that they therefore transferred the campaign to Italy. But where would Bonaparte have been had Moreau won Hohenlinden in the spring of 1800 while he remained ingloriously at Paris? While therefore in writing to Moreau he carefully adopts the language of one who, much to his own regret, has become a mere civilian, he plans the campaign so that both Moreau and Masséna are confined to the task of holding the enemy in play while an army of reserve descends from one of the Alpine passes into Italy. This army of reserve, which was so carefully concealed that few people believed in its existence, is to be commanded, he writes, by some general "to be named by the consuls"; a little later Berthier is nominated. As late as the end of March he told Miot that he did not mean to leave Paris. Moreau is also to detach 25,000 men under Lecourbe, who are to join Berthier in Italy; in this way security was taken that Moreau should not be too successful. On April 24 the campaign in Germany began by the passage of the Rhine at a number of points at once. Up to May 10 Moreau is the hero of the war. He is victorious at Engen, at Mösskirchen, and forces Kray to retire to Ulm. But on May 9 Bonaparte is at Geneva, and it appears at once that he is commander, and Berthier only his chief of the staff. At the same time Carnot in person is sent with unusual formality to demand from Moreau the detachment of troops.

Campaign of Marengo. The campaign of Marengo was astonishingly short. On May 11 Bonaparte left Geneva, and he is in Paris again before the end of June. Since the beginning of April Masséna had been struggling vainly against the superior forces of Melas; since the 21st he had been shut up in Genoa, where Austria and England could co-operate in the siege. In Italy the affairs of France looked darker than ever, when Bonaparte threw himself on the rear of Melas by passing the Great St Bernard between May 15 and 20. Other divisions passed the Little St Bernard and the Mont Cenis, while the detachment from Moreau's army (under Moncey, not Lecourbe) descended the St Gotthard. It seems that the Austrians had absolutely refused to believe, what nevertheless was openly discussed in the Paris journals, that Bonaparte intended to cross the Alps. Bonaparte had another surprise in store for them. Though Genoa was now suffering all the horrors of famine, he made no attempt to relieve it, but turned to the left, entered Milan, and took possession of the whole line of the Ticino and the Po. Meanwhile Genoa capitulated to General Ott. Melas was now at Alessandria, where Bonaparte sought him on the 13th. On the 14th Melas marched out, crossed the Bormida, and arrived at Marengo. The victory here won by Bonaparte, though in its consequences more decisive than any other, and marking in a certain sense the culmination of his career, yet was due almost entirely to accident. A sudden charge of cavalry by Kellermann changed a great Austrian victory into a decisive Austrian defeat. On the next day Melas (having, as it seems, quite lost his head) signed a convention by which Austria sacrificed almost all North Italy, restoring something like the position of Campo Formio. "Had he fought another battle," says Marmont, "he would certainly have beaten us." Bonaparte returns to Paris, victorious at once over Austria and over Moreau and Masséna. He did not, however, succeed in tearing from Moreau the honour of concluding the war. Marengo did not lead to peace; this was won, where naturally it could only be won, in Bavaria by Moreau's victory of Hohenlinden (December 3d), a victory perhaps greater than any of which at that time Bonaparte could boast.

Never was Bonaparte more recklessly audacious, never was he more completely and undeservedly successful, than in this campaign. Brumaire had given him a very uncertain position. Sieyès and the republicans were on the watch for him on the one side; Moreau seemed on the point of eclipsing him on the other. His family felt their critical position: "had he fallen at Marengo," writes Lucien, "we should have been all proscribed." Perhaps nothing but a stroke so rapid and startling as that of Marengo could have saved him from these difficulties. But this did more, and developed the empire out of the consulate.

His appeal for peace after Brumaire had not been purely insincere, though he wanted victory before peace. He proposes to Rouget de l'Isle to write "a battle hymn which shall express the idea that with great nations peace comes after victory." After Marengo he devotes himself to giving peace to the world; he did this by three great acts, so that in 1802 for the first time for ten years under the new Augustus "no war or battle sound was heard the world around." These three acts are the treaty of Lunéville, February 1801, the Concordat, July 1801, the treaty of Amiens, March 1802. It is worth noticing that the negotiator of all of them is his brother Joseph, as if he especially desired to connect his family name with the pacification of the world.

Treaty of Lunéville. 1. The treaty of Lunéville gave peace to the Continent. It is to be observed that here Bonaparte shows himself at least less rapacious than the Directory. He surrenders

most of the usurpations of 1798, the Roman and Parthenopean Republics, and returns in the main to the arrangements of Campo Formio,—a proof of moderation which must have led the cabinets to consider whether after all it might not be possible to find a *modus vivendi* with the Government of Brumaire.

The Concordat. 2. By the Concordat he professed to close the religious war. In reality he crushed the national Gallican Church, which had been created by the Constitution Civile, and which had perhaps begun to take root, and restored the Papal Church, shorn of its endowments and dependent, so long as he lived, on the state. As part of the great pacification, the Concordat was perhaps mainly a stroke of stage-effect, though its influence upon the later history of France has been great. For Bonaparte himself it was important as severing the clerical party from the Bourbons and attaching it to himself, as giving him through the clergy an influence over the peasantry, upon whom he depended for his armies, also as in some degree welding together through the ubiquitous influence of the clergy the different states which were already subject to his government. In negotiating it with Cardinal Consalvi, Bonaparte had recourse more than once to the vulgar fraud and knavery which earned for him the title of Jupiter-Scapin.

Treaty of Amiens. 3. After the treaty of Lunéville, as after that of Campo Formio, England was left to fight France alone; but Bonaparte had now a higher estimate than in 1798 of England's naval power. He was able, however, in 1801 to attack her in another way. By her conduct at Malta she had given offence to the czar Paul, and taking advantage of this Bonaparte was able to revive against her the armed neutrality of 1780. Not only Russia but Prussia was thus brought for the first time, along with Sweden and Denmark, into the French alliance, and the system of Tilsit was for the first time sketched out. But it lasted only for a moment. At the beginning of April the announcement of the murder of Paul and the bombardment of Copenhagen by Nelson dissolved it. England and France were now alike disposed for peace, the former because she had lost the support of a European Coalition, the latter because she had lost all means of attack, and also because of Bonaparte's grand plan of pacification. In the summer Bonaparte's endeavours are confined to saving the French colony in Egypt from the English, and to snatching a little territory from England's ally Portugal by means of Spain. But Cairo capitulated to the English in June, in which month also Spain made peace with Portugal. Accordingly in October the preliminaries of London were signed, and the treaty of Amiens followed in March. The allies of France paid for her naval defeats, Spain losing Trinidad and Holland Ceylon; but France, though she lost nothing, acquiesced by this treaty in the total failure of all her designs upon the East.

The globe was now at peace, and thanked Bonaparte for it. The equilibrium which had been destroyed by the Revolution seemed at length to be restored. Meanwhile the legislative reconstruction of France proceeded rapidly. This is the glorious period of Bonaparte's life, not, as has often been alleged, because he was as yet uncorrupted by power, but simply because a strong intelligent Government was the great need of France and repose the great need of Europe, and Bonaparte at this time satisfied both needs.

Reconstruction of French institutions. The work of reconstruction which distinguishes the consulate, though it was continued under the empire, is the most enduring of all the achievements of Napoleon. The institutions of modern France date, not, as is often said, from the Revolution, but from the consulate. Not that Napoleon personally was endowed with a supreme legislative genius; his principal merit was to have given to France the first secure Government, the first Government capable of effective legislation, that she had had since the destruction of her ancient institutions. The task of reconstruction fell to him of necessity; his personal interference was in many respects, as we shall see, mischievous rather than beneficial; it is, however, also true that he appreciated the greatness of the work, urged it on with vigour, entered into it, impressed it with the stamp of his own personality, and left upon it the traces of his keen sagacity.

The institutions now created, and which form the organization of modern France, are—(1) the restored Church, resting on the Concordat; (2) the University, resting on the law of 11 Floréal, An X. (May 1, 1802); (3) the judicial system, commenced by the law of 27 Ventose, An VIII. (March 18, 1800), and completed by other laws in 1810; (4) the Codes:—(*a*) Code Civil (commission nominated 24 Thermidor, An VIII., August 12, 1800; it received the name Code Napoléon on September 3, 1807), (*b*) Code de Commerce, promulgated on September 10, 1807, (*c*) Code Pénal, (*d*) Code d'Instruction Criminelle (came into force January 1, 1811); (5) the system of local government, resting on the law of 18 Pluviose, An VIII. (February 7, 1800); (6) the Bank of France, established 28 Nivose, An VIII. (January 18, 1800); (7) the Legion of Honour, established 29 Floréal, An X. (May 19, 1802). These institutions, along with the military system, have in the main continued to the present day after the downfall of all the Napoleonic institutions which were purely political. It is rather the fortune than the merit of Napoleon that no similar mass of legislation can be ascribed to any other sovereign, since no other sovereign has ruled securely over an ancient and civilized country which has been suddenly deprived of all its institutions. It is also a matter of course that much of this legislation has been beneficial, since a *tabula rasa* relieves the legislator of many hindrances. In several points, on the other hand, we can see that France was sacrificed to Napoleon's personal interest. Thus the Concordat restored the ancient Papal Church, shorn of its wealth, and receiving from the state a subsidy of about £2,000,000. It was right to restore religion, and the Constitution Civile, which was cancelled by the Concordat, had been an insane act, the principal cause of the miseries of France for ten years. Nevertheless a great opportunity was lost of trying some new experiment, which might have led to a genuine revival of religion; but for this Napoleon cared nothing so long as he could pose as a new Constantine, detach the church from the cause of the Bourbons, and have the pope at his beck. In like manner the freedom of local government was sacrificed to the exigencies of his despotism. Among the most remarkable of his institutions was the University. The twenty-one universities of old France, including the great mother university of Paris, had fallen victims in 1792 to the insanity of the Legislative Assembly; nothing of the least efficiency had been established in their place, so that in March 1800 Lucien Bonaparte could write, "since the suppression of the teaching corporations instruction has almost ceased to exist in France." By laws of May 1806 and March 1808 was founded the modern University, that is, the whole teaching profession formed into a corporation and endowed by the state, a kind of church of education. This remarkable institution still exists. It has far too much centralization, and is in no way equal to the old system when that is intelligently worked, as in Germany; many learned men have severely condemned it; still it was a great constructive effort, and gave Napoleon the occasion for some striking and original remarks.

From the time of the battle of Marengo the system of Brumaire began to take a development which perhaps

had not been clearly foreseen. Sieyès had wished to confine Bonaparte to the war department, Moreau perhaps had wished to keep him at Paris; in either case it had not been intended to create an august monarchy. But the fabulous success of Marengo, joined to the proofs Bonaparte gave of a really superior intelligence and commanding character, turned the French mind back into that monarchical groove in which it had so long run before the Revolution. Popular liberty had been already renounced by Sieyès, and the disastrous failure of republican institutions, which in four years, from 1795 to 1799, had brought the country to bankruptcy, civil war, and almost barbarism, inclined all public men to agree with him. The choice then could only lie between some form of aristocracy and the revival of monarchy either in the Bourbon family or in another. Napoleon's personal character decided this question. By the Concordat he wrested from the Bourbons the support of the church; by his military glory he seduced the noblesse, as is seen in the case of Ségur; by the pacification of the world he half reconciled to himself the foreign cabinets. But no sooner did this new form of monarchy begin to appear than Bonaparte began to find himself surrounded by new dangers. He was exposed to the hatred of the republicans, who had hitherto been appeased by the title of consul, and were now thrown into coalition with the defeated Jacobins, and also to the despair of the royalists, who saw themselves disappointed of restoration at the moment of the failure of republicanism. Nearer his person at the same time court-parties began to spring up. His brothers and sisters with Corsican shamelessness began to claim their share in the spoils. While he doubted what form his monarchy should take, and whether some character greater and more unique than that of a hereditary king could not be invented, they urged the claims of the *family*. Thus arose a standing feud between the Bonapartes and the Beauharnais, who in the interest of Josephine, already dreading divorce for her childlessness, opposed the principle of heredity.

In grappling with the defeated parties Bonaparte found a great advantage in his position. The constitution of Brumaire itself gave him great powers; popular institutions had been destroyed, not by him, but by the nation itself, which was weary of them; under the Directory the public had grown accustomed to the suppression of journals and to periodic *coups d'état* of the most savage violence. Bonaparte therefore could establish a rigorous despotism under the forms of a consular republic, mutilate the assemblies, and silence public opinion; he could venture occasionally upon acts of the most sweeping tyranny without shocking a people which had so lately seen Fructidor, not to say the Reign of Terror, and had been accustomed to call them liberty. The conspiracies began immediately after the return from Marengo, when the Corsicans Arena and Ceracchi, guilty apparently of little more than wild talk, were arrested in October 1800 at the Théâtre Français. But on December 24th of the same year, as he drove with Josephine to the opera, a sudden explosion took place in the Rue Saint-Nicaise, which killed and wounded several people and damaged about fifty houses; the carriage of Bonaparte escaped. He was still in the first fervour of his conversion from Jacobinism, and had not yet become alive to the danger to which he was exposed from royalism. He could therefore see nothing but Jacobinism in this plot, and proposed to meet the danger by some general measure calculated to eradicate what remained of the Jacobin party. But before this measure could be taken Fouché convinced him that he had been in error, and that he was in the presence of a new enemy, royalism roused into new vigour by the recent change in public opinion. Upon this Bonaparte acted most characteristically. By a singular stretch of Machiavelism he made use of the mistake into which he had himself led the public to crush the enemy which for the moment he feared most. He arrested and transported one hundred and thirty persons, whom he knew to be innocent of the plot, on the general ground of Jacobinism, substituting for all legal trial a resolution passed by the servile senate to the effect that "the measure was conservative of the constitution." This is Nivose, an act as enormous as Fructidor, and with a perfidy of its own.

Making use of victory was almost more Bonaparte's talent than winning it. These plots, so far from impeding his ascent to monarchy, were converted by him into steps upon which he mounted. They were so many arguments for heredity, which, in case Bonaparte should fall a prey to them, would furnish a successor. It had already been argued in the *Parallèle entre César, Cromwell, et Bonaparte* (October 1800) that heredity only could prevent the nation from falling again under the domination of the assemblies, under the yoke of the S (not Sieyès surely but Soldats) or under that of the Bourbons. He also made the plot of Nivose the occasion of a constitutional innovation. The assemblies devised by Sieyès had hitherto been simply useless, so much idle machinery. But in Nivose the precedent was set of giving the Senate a constituent power. To guard the constitution was its nominal function; this was now converted into a function of sanctioning alterations in the constitution, since every innovation became legal when the Senate declared it to be conservative of the constitution. In the hands of Bonaparte such a principle soon became fruitful enough.

The first open step towards monarchy was made at the conclusion of the treaty of Amiens. As pacificator of the globe, it was declared in the tribunate that Bonaparte deserved some mark of public gratitude. Upon this the Senate proposed to re-elect him First Consul for a further term of ten years. Bonaparte, disappointed, declared that he could only owe a prorogation of his magistracy to the people; to them therefore the question was referred, but in the form, Shall Napoleon Bonaparte be elected consul for life? and in this form it was adopted. Before the final step was taken and the First Consul transformed himself into the Emperor Napoleon, a great and portentous change had taken place in the spirit of his government. Before the year 1803 there was no fair reason to conclude that Bonaparte was too fond of war. For the two wars of the Revolution he had not been responsible: the first broke out when he was in Corsica, the second when he was in Egypt. But both wars had been brought to an end by him; he had closed the Temple of Janus, he was the great pacificator. In constructive legislation he had shown such zeal that it was easy to imagine him, though a great commander, as one who was capable of feeling the blessedness of the peacemaker. These illusions began to vanish in 1803 at the rupture of the peace of Amiens. This year 1803 is the turning-point in his life, and a great turning-point in French history. It may be considered the first year of modern France. The Revolution is at last over; the new organization begins to work regularly. The old noblesse is gone, and in place of the old Church there is the humbled Church of the Concordat. France is covered with an army of functionaries, servilely dependent on the Government; a strange silence has settled on the country which under the old régime had been noisy with the debate—if for the most part fruitless debate—of parliaments and estates. The Government is tenfold more imperious than it had been before 1789. And now it appears that Bonaparte had desired only the glory of having made peace, not peace itself, just as earlier, after making the peace of Campo Formio, he had taken measures by the Egyptian expedition to embroil Europe

Rupture with England. again. What he wants is to complete his military success by humbling England. He had failed in 1798, when he had controlled but a small part of the power of France, a single army shut up in Egypt, when the French Government had been feeble and unintelligent, when England had been able to rally a European Coalition to her side. But surely he would succeed now, when the whole power of France, drawing after it Spain, Holland, Switzerland, and North Italy, was in his single hand, and when he could add the fleets of the other maritime powers to that of France; especially as coalitions against France seemed out of date, since Russia and Prussia had been united against England in 1801, and Germany was now suffering internal transformation under the united influence of France and Russia. But after so many years of war could he call on France for another effort? In the first place all the new institutions of France, having grown up in war, were adapted for war rather than for anything else; in the second place he hoped to spare the French all war-taxation by making the expense fall upon the allies.

From this memorable rupture flowed all the terrible events of the Napoleonic age. It is in one respect difficult to understand, because in the eleven years of the war with England Bonaparte was never able to strike a single blow at his enemy, while that enemy destroyed his fleets, conquered his colonies, and by arming all Europe against him at length brought down his power. Why did Bonaparte engage in a war in which he was condemned to be so purely passive? It seems that, as in 1798, he totally miscalculated the English maritime power, and that in 1803, though to Lord Whitworth he spoke of the invasion of England as almost impossible, yet in reality he expected to achieve that impossibility, as he had achieved so many others. Thus the angry negotiation with Lord Whitworth, the stormy scene at the Tuileries, the violent detention of the English residents in France at the moment of the rupture, are to be regarded as studied contrivances by which he concealed the wantonness of his breach of the European peace and tried to throw the blame of it upon the English. That he was really bent upon forcing a war appears from his allowing Sébastiani's report of his mission in the East, full of hints of the intention of France to re-occupy Egypt at the first opportunity, to appear in the *Moniteur*. This report, besides offending England, caused her to keep resolute possession of Malta, and, when Bonaparte appealed to the treaty of Amiens, England replied by pointing to the new annexations of France, which had just divided Piedmont into departments. "Ce sont des bagatelles," Lord Whitworth reports Bonaparte to have answered, but he adds in a parenthesis which has never been printed, "The expression he made use of was too trivial and vulgar to find a place in a despatch or anywhere but in the mouth of a hackney coachman!"

By this rupture Europe relapsed into the fearful disorder from which Brumaire seemed to have rescued it; only in place of revolutionary fanaticism the disturbing cause was now the deliberate calculating ambition of a great general and crafty politician, who already commanded the resources of a large part of Europe. This same year 1803 saw the first steps taken towards the subjugation of Germany. The annexation to France of the left bank of the Rhine led to a revolution in the Germanic system and to a complete transformation of the Diet, by which Austria lost the greater part of her influence over the minor German states; this influence passed to France. As soon as the rupture with England took place Bonaparte took up a position in the heart of Germany by seizing Hanover.

All this was done while Bonaparte was still nominally only consul in the French republic. But the rupture with England furnished him with the occasion of throwing off the last disguise and openly restoring monarchy. It was a step which required all his audacity and cunning. He had crushed Jacobinism, but two great parties remained. There was first the more moderate republicanism, which might be called Girondism, and was widely spread among all classes and particularly in the army. Secondly, there was the old royalism, which after many years of helpless weakness had revived since Brumaire. These two parties, though hostile to each other, were forced into a sort of alliance by the new attitude of Bonaparte, who was hurrying France at once into a new revolution at home and into an abyss of war abroad. England too, after the rupture, favoured the efforts of these parties. Royalism from England began to open communications with moderate republicanism in France. Pichegru acted for the former, and the great representative of the latter was Moreau, who had helped to make Brumaire in the tacit expectation probably of rising to the consulate in due course when Bonaparte's term should have expired, and was therefore hurt in his personal claims as well as in his republican principles. Bonaparte watched the movement through his ubiquitous police, and with characteristic strategy determined not merely to defeat it but to make it his stepping stone to monarchy. He would ruin Moreau by fastening on him the stigma of royalism; he would persuade France to make him emperor in order to keep out the Bourbons. He achieved this with the peculiar mastery which he always showed in villainous intrigue. Moreau had in 1797 incurred blame by concealing his knowledge of Pichegru's dealings with the royalists. That he should now meet and hold conversation with Pichegru at a moment when Pichegru was engaged in contriving a royalist rebellion associated his name still more closely with royalism, and Pichegru brought with him wilder partisans such as Georges the Chouan. That Moreau would gladly have seen and gladly have helped an insurrection against Bonaparte is certain; any republican, and what is more any patriot, would at that moment have risked much to save France from the ruin that Bonaparte was bringing on her. But Bonaparte succeeded in associating him with royalist schemes and with schemes of assassination. Controlling the Senate, he was able to suppress the jury; controlling every avenue of publicity, he was able to suppress opinion; and the army, Moreau's fortress, was won through its hatred of royalism. In this way Bonaparte's last personal rival was removed. There remained the royalists, and Bonaparte hoped to seize their leader, the Comte d'Artois, who was expected, as the police knew, soon to join Pichegru and Georges at Paris. What Bonaparte would have done with him we may judge from the course he took when the Comte did not come. On March 15, 1804, the Duc d'Enghien, grandson of the Prince de Condé, residing at Ettenheim in Baden, was seized at midnight by a party of dragoons, brought to Paris, where he arrived on the 20th, confined in the castle of Vincennes, brought before a military commission at 2 o'clock the next morning, asked whether he had not borne arms against the republic, which he acknowledged himself to have done, conducted to a staircase above the moat and there shot, and buried in the moat. Execution of the Duc d'Enghien.

This deed was perfectly consistent with Bonaparte's professed principles, so that no misunderstanding or passing fit of passion is required to explain it. He had made, shortly before, a formal offer to the pretender through the king of Prussia, by which he had undertaken to pay him a handsome pension in return for the formal abdication of his rights. This had been refused, and Bonaparte felt free. That the best course was to strike at the heads of the family was a shrewd conclusion. Neither Louis nor Charles were precisely heroes; and then the whole re-

volutionary party in France would applaud a new tragedy like that of January 1793. (Accordingly Bernadotte and Curée were delighted with it.) That the Duc d'Enghien was innocent of the conspiracy was nothing to the purpose; the act was political, not judicial; accordingly he was not even charged with complicity. That the execution would strike horror into the cabinets, and perhaps bring about a new Coalition, belonged to a class of considerations which at this time Bonaparte systematically disregarded.

This affair led immediately to the thought of giving heredity to Bonaparte's power. The thought seems to have commended itself irresistibly even to strong republicans and to those who were most shocked by the murder. To make Bonaparte's position more secure seemed the only way of averting a new Reign of Terror or new convulsions. He himself felt some embarrassment. Like Cromwell, he was afraid of the republicanism of the army, and heredity pure and simple brought him face to face with the question of divorcing Josephine. To propitiate the army he chose from the titles suggested to him—consul, stadtholder, &c.—that of emperor, undoubtedly the most accurate, and having a sufficiently military sound. The other difficulty, after much furious dissension among the two families of Bonaparte and Beauharnais, was evaded by giving Napoleon himself (but none of his successors) a power of adoption, and fixing the succession, in default of a direct heir natural or adoptive, first in Joseph and his descendants, then in Louis and his descendants. Except abstaining from the regal title, no attempt was made to conceal the abolition of republicanism. Bonaparte was to be called Napoleon, and "sire" and "majesté"; grand dignitaries with grand titles were appointed; and "citoyen" from this time gave way to "monsieur." The change was made by the constituent power of the Senate, and the senatus-consulte is dated May 18, 1804.

or
eon.

It required some impudence to condemn Moreau for royalism at the very moment that his rival was re-establishing monarchy. Yet his trial began on May 15th. The death of Pichegru, nominally by suicide, on April 6th had already furnished the rising sultanism with its first dark mystery. Moreau was condemned to two years' imprisonment, but was allowed to retire to the United States.

These changes destroyed all that remained of the political life of France. Jacobinism had been eradicated in Nivose; republicanism and royalism were paralysed now. Henceforth there was no power or person in France but Bonaparte, and over Europe there hung a danger more terrible than had ever threatened it before. The combined resources of several countries and an unparalleled military force were at the absolute disposal of a general and administrator of commanding ability, who had shown by the manner of his rupture with England that he was bent upon undertaking vast military enterprises. This danger, which was clearly visible early in 1804, could not be averted. His scheme indeed failed. He did not conquer England, nor recover Malta and reoccupy Egypt. His forces were drawn in another direction. But, if England suffered less, Europe suffered far more than could have been feared in 1804. The wars which now begin are not, like those of the French Revolution, wars of principle, for the principles of the Revolution have been recanted and are held by no one in so much contempt as by Bonaparte. Nor are they armed litigations like the old wars of Europe, but unique experiments in which millions of lives are sacrificed to the ambition of an individual.

Throughout 1804 and the first part of 1805 the policy of Bonaparte is such as might be called insane, if he had had the ordinary objects of a ruler; it is explained by the consideration that he wants war, even if it should be war with all the world. He had acted in a similar way in 1798. In thinking that he should profit by war he was not mistaken. Had he only gone to war with the whole Continent at once, he would not, as the event proved, have overestimated his strength. But he was not, in the long run, a match for England and the Continent together; he made at starting the irremediable mistake of not dividing these two enemies. He seems indeed to have set out with a monstrous miscalculation which might have ruined him very speedily, for he had laid his plan for an invasion of England and a war in Europe at the same time. If we imagine the invasion successfully begun, we see France thrown back into the position of 1799, her best general and army cut off from her by the sea, while Austria, Russia, and perhaps Prussia pour their armies across the Rhine; but we see that the position would have been far worse than in 1799, since France without Bonaparte in 1805 would have been wholly paralysed. As it was, the signal failure of his English enterprise left room for a triumphant campaign in Germany, and Ulm concealed Trafalgar from the view of the Continent. The European Coalition had been disarmed since Brumaire by the belief that Bonaparte's Government was less intolerably aggressive than that of the Directory; this belief gave place in 1803 to a conviction that he was quite as aggressive and much more dangerous. England therefore might hope to revive the Coalition, and in the spring of 1804 she recalled Pitt to the helm in order that he might do this. The violent proceedings of Bonaparte on the occasion of the rupture, his occupation of Hanover, his persecution of the English representatives in Germany,—Spencer Smith at Stuttgart, Drake at Munich, Sir G. Rumbold at Hamburg,—created an alarm in the cabinets greater than that of 1798, and the murder of D'Enghien shocked as much as it alarmed them. Positive conquest and annexation of territory too now went on as rapidly and as openly as in 1798. The new empire compared itself to that of Charlemagne, which extended over Italy and Germany, and on December 2, 1804, a parody of the famous transference of the empire took place in Notre Dame, the pope (Pius VII.) appearing there to crown Napoleon, who, however, took the crown from his hands and placed it himself upon his own head. Meanwhile the Italian republic was changed into a kingdom, which at first Bonaparte intended to give to his brother Joseph, but in the end accepted for himself. In the first months of 1805, fresh from the *sacre* in Notre Dame, he visited Italy and received the iron crown of the Lombard kings at Milan. Soon after the Ligurian republic was annexed, and a principality was found for his brother-in-law Bacciochi in Lucca and Piombino. By these acts he seemed to show himself not only ready but eager to fight with all Europe at once. It was not his fault that in the autumn of 1805, when he fought with Austria and Russia in Germany, he was not also maintaining a desperate struggle in the heart of England; it was not his fault that Prussia was not also at war with him, for his aggressions had driven Prussia almost to despair, and only once—that is, in the matter of Sir G. Rumbold—had he shown the smallest consideration for her. And yet at first fortune did not seem to favour him.

Designs against England and the Continent.

Napoleon crowned.

Had public opinion been less enslaved in France, had the frivolity of the nation been less skilfully amused by the operatic exhibitions of the new court and the *sacre* in Notre Dame, it would have been remarked that, after most needlessly involving France in war with England, Bonaparte had suffered half the year 1803, all the year 1804, and again more than half the year 1805 to pass without striking a single blow, that after the most gigantic and costly preparations the scheme of invasion was given up, and that finally France suffered a crushing defeat at Trafalgar which paralysed her on the side of England for the rest of

the war. In order to understand in any degree the course he took, it seems necessary to suppose that the intoxication of the Marengo campaign still held him, that as then, contrary to all expectation, he had passed the Alps, crushed his enemy, and instantly returned, so now he made no doubt of passing the Channel, signing peace in London, and returning in a month with a fabulous indemnity in his pocket to meet the Coalition in Germany. To conquer England it was worth while to wait two years, but his position was very critical when, after losing two years, he was obliged to confess himself foiled. He retrieved his position suddenly, and achieved a triumph which, though less complete than that which he had counted on, was still prodigious,—the greatest triumph of his life. At the moment when his English scheme was ending in deplorable failure, he produced another, less gigantic but more solid, which he unfolded with a rapid precision and secrecy peculiar to himself. In the five years which had passed since Marengo his position for the purposes of a Continental war had improved vastly. Then he had no footing either in Germany or Italy, and his new office of First Consul gave him a very precarious control over the armies, which themselves were in a poor condition. Now his military authority was absolute, and the armies after five years of imperialism were in perfect organization; he had North Italy to the Adige; he had Hanover; and since the Germanic revolution of 1803 Bavaria, Würtemberg, and Baden had passed over to his side. Therefore as the Coalition consisted only of Austria, Russia, and England he might count upon success, and the more confidently if he could strike Austria before the arrival of the Russian army. It is strange that in this estimate it should be unnecessary to take Prussia into the account, since the Prussian army (consisting of 250,000 men) was at that time supposed to be a match by itself for the French. At the last moment, and in the midst of the Austerlitz campaign, Napoleon might have been brought near to ruin by a sudden resolution on the part of the king of Prussia, and it is to be added that he did not escape this risk by any circumspection of his own. But for ten years Prussia had been rooted in the strangest system of immovable neutrality, and in this war both sides had to put up with the uncertainty whether the prodigious weight of the army of Frederick would not be thrown suddenly either into its own or into the opposite scale. It was at the end of August 1805 that Napoleon made his sudden change of front. At the beginning of that month he had been still intent on the invasion of England; ever since March maritime manœuvres on an unparalleled scale had been carried on with the object of decoying the English fleets away from the Channel, and so giving an opportunity for the army of invasion to cross it in a flotilla under the protection of French fleets. But in spite of all manœuvres a great English fleet remained stationary at Brest, and Nelson, having been for a moment decoyed to Barbados, returned again. In the last days of August Admiral Villeneuve, issuing from Ferrol, took alarm at the news of the approach of an English fleet, and instead of sailing northward faced about and retired to Cadiz. Then for the first time Napoleon admitted the idea of failure, and saw the necessity of screening it by some great achievement in another quarter. He resolved to throw his whole force upon the Coalition, and to do it suddenly. Prussia was to be bribed by the very substantial present of Hanover.

Five years had passed since Napoleon had taken the field when the second period of his military career began. He now begins to make war as a sovereign with a boundless command of means. For five years from 1805 to 1809 he takes the field regularly, and in these campaigns he founds the great Napoleonic empire. By the first he breaks up the Germanic system and attaches the minor German states to France, by the second he humbles Prussia, by the third he forces Russia into an alliance, by the fourth he reduces Spain to submission, by the fifth he humbles Austria. Then follows a second pause, during which for three years Napoleon's sword is in the sheath, and he is once more ruler, not soldier.

From the beginning of this second series of wars the principles of the Revolution are entirely forgotten by France, which is now a monarchy and even a propagator of monarchical principles.

Napoleon's strategy always aims at an overwhelming surprise. As in 1800, when all eyes were intent on Genoa, and from Genoa the Austrians hoped to penetrate into France, he created an overwhelming confusion by throwing himself across the Alps and marching not upon Genoa but upon Milan, so now he appeared not in front of the Austrians but behind them and between them and Vienna. The wavering faith of Bavaria had caused the Austrians to pass the Inn and to advance across the country to Ulm. It was intended that the Russians should join them here, and that the united host should invade France, taking Napoleon, as they fondly hoped, by surprise. So often unfortunate in their choice of generals, they had this time made the most unfortunate choice of all. Mack, who at Naples in 1799 had moved the impatient contempt of Nelson, now stood matched against Napoleon at the height of his power. He occupied the line of the Iller from Ulm to Memmingen, expecting the attack of Napoleon, who personally lingered at Strasburg, in front. Meanwhile the French armies swarmed from Hanover and down the Rhine, treating the small German states half as allies half as conquered dependants, and disregarding all neutrality, even that of Prussia, till they took up their positions along the Danube from Donauwörth to Ratisbon far in the rear of Mack. The surprise was so complete that Mack, who in the early days of October used the language of confident hope, on the 19th surrendered at Ulm with about 26,000 men, while another division, that of Werneck, surrendered on the 18th to Murat at Nördlingen. In a month the whole Austrian army, consisting of 80,000 men, was entirely dissolved. Napoleon was master of Bavaria, recalled the elector to Munich, and received the congratulations of the electors of Würtemberg and Baden (they had just at this time the title of electors). It was the stroke of Marengo repeated, but without a doubtful battle and without undeserved good luck.

Campaign against Austria and Russia.

Capitulation of Ulm.

After Marengo it had been left to Moreau to win the decisive victory and to conclude the war; this time there was no Moreau to divide the laurels. The second part of the campaign begins at once; on October 28 Napoleon reports that a division of his army has crossed the Inn. He has now to deal with the Russians, of whom 40,000 men have arrived under Kutusoff. He reaches Linz on November 4, where Gyulai brought him the emperor's proposals for an armistice. He replies by demanding Venice and Tyrol and insisting upon the exclusion of Russia from the negotiations, conditions which, as he no doubt foresaw, Gyulai did not think himself authorized to accept. But Napoleon did not intend this time, as in 1797 and in 1800, to stop short of Vienna. Nothing now could resist his advance, for the other Austrian armies, that of the archduke John in Tyrol and that of the archduke Charles on the Adige, were held in play by Ney and Masséna, and compelled at last, instead of advancing to the rescue, to retire through Carniola into Hungary. On November 14 he dates from the palace of Schönbrunn; on the day before Murat had entered Vienna, which the Austrian emperor, from motives of humanity, had

resolved not to defend, and the French also succeeded by an unscrupulous trick in getting possession of the bridges over the Danube. So far his progress had been triumphant, and yet his position was now extremely critical. The archduke Charles was approaching from Hungary with 80,000 Austrians; another Russian army was entering Moravia to join Kutusoff, who had with great skill escaped from the pursuit of Murat after the capture of Vienna. Napoleon, though he had brought 200,000 men into Germany, had not now, since he was obliged to keep open his communications down the valley of the Danube, a large army available for the field. But, what was much more serious, he had recklessly driven Prussia into the opposite camp. He had marched troops across her territory of Ansbach, violating her neutrality, and in consequence on November 3 (while Napoleon was at Linz) she had signed with Russia the treaty of Potsdam, which practically placed 180,000 of the most highly drilled troops in the world at the service of the Coalition. Such had been Napoleon's rashness, for his audacious daring was balanced indeed by infinite cunning and ingenuity, but was seldom tempered by prudence. In this position, it may be asked, how could he expect ever to make his way back to France? What he had done to Mack Prussia would now do to him. The army of Frederick would block the Danube between him and France, while the Russians and Austrians united under the archduke would seek him at Vienna.

As at Marengo, fortune favoured his desperate play. The allies had only to play a waiting game, but this the Russians and their young czar, who was now in the Moravian headquarters, would not consent to do. He was surrounded by young and rash counsellors, and the Russians, remembering the victories of Suwaroff in 1799, and remarking that almost all Napoleon's victories hitherto had been won over Austrians, had not yet learned to be afraid of him. Napoleon became aware of their sanguine confidence from Savary, whom he had sent to the czar with proposals; he contrived to heighten it by exhibiting his army as ill-prepared to Dolgorouki, sent to him on the part of the czar. The end was that the Russians (80,000 men, aided by about 15,000 Austrians) rushed into the battle of Austerlitz (December 2, 1805), which brought the third Coalition to an end, as that of Hohenlinden had brought the second. Nowhere was Napoleon's superiority more manifest; the Russians lost more than 20,000 men, the Austrians 6000. The former retired at once under a military convention, and before the year 1805 was out the treaty at Pressburg was concluded with Austria (December 26) and that of Schönbrunn with Prussia (December 15).

Battle of Austerlitz.

It was a transformation-scene more bewildering than even that of Marengo, and completely altered the position of Napoleon before Europe. To the French indeed Austerlitz was not, as a matter of exultation, equal to Marengo, for it did not deliver the state from danger, but only raised it from a perilous eminence to an eminence more perilous still. But as a military achievement it was far greater, exhibiting the army at the height of its valour and organization (the illusion of liberty not yet quite dissipated), and the commander at the height of his tactical skill; and in its historical results it is greater still, ranking among the great events of the world. For not only did it found the ephemeral Napoleonic empire by handing over Venetia to the Napoleonic monarchy of Italy, and Tyrol and Vorarlberg to Napoleon's new client Bavaria; it also destroyed the Holy Roman Empire while it divided the remains of Hither Austria between Würtemberg and Baden. In the summer of 1806 the emperor of Austria (he had this title since 1804) solemnly abdicated the title of Roman emperor; the ancient diet of Ratisbon was dissolved, and a new organization was created under the name of Confederation of the Rhine, in which the minor states of Germany were united under the protectorate of Napoleon. Bavaria and Würtemberg at the same time were raised into kingdoms. In all the changes which have happened since, the Holy Roman Empire has never been revived, and this event remains the greatest in the modern history of Germany.

But Austerlitz was greater than Marengo in another way. That victory had a tranquillizing effect, and was soon followed by a peace which lasted more than four years. But the equilibrium established after Austerlitz was of the most unstable kind; it was but momentary, and was followed by a succession of the most appalling convulsions; the very report of the battle was fatal to William Pitt. A French ascendency had existed since 1797, and Napoleon's Government had at first promised to make it less intolerable. Since 1803 this hope had vanished, but now suddenly the ascendency was converted into something like a universal monarchy. Europe could not settle down. The first half of 1806 was devoted to the internal reconstruction of Germany and to the negotiation of peace with the two great belligerents who remained after Austria and Prussia had retired, viz., England and Russia. But these negotiations failed, and in failing created suddenly a new Coalition. In England, Fox showed unexpectedly all the firmness of Pitt; and the czar refused his ratification to the treaty which his representative at Paris, D'Oubril, had signed. But the negotiations had gone far enough to give Prussia deep offence. At a moment when she found herself almost shut out of the German world by the new Confederation, Napoleon was found coolly treating with England for the restoration of Hanover to George III. In August 1806, just at the moment of the dissolution of the Holy Roman Empire and the formation of the Confederation of the Rhine, Prussia suddenly mobilized her army, and about the same time Russia rejected the treaty. This amounted practically to a new Coalition, or to a revival of the old one with Prussia in the place of Austria. No one knew so well as Napoleon the advantage given by suddenness and rapidity. The year before he had succeeded in crushing the Austrians before the Russians could come up; against Prussia he had now the advantage that she had long been politically isolated, and could not immediately get help either from Russia or England,—for the moment only Saxony and Hesse-Cassel stood by her,—while his armies, to the number of 200,000 men, were already stationed in Bavaria and Swabia, whence in a few days they could arrive on the scene of action. The year before Austria had been ruined by the incapacity of Mack; Prussia now suffered from an incapacity diffused through the higher ranks both of the military and civil service. Generals too old, such as Brunswick and Möllendorf, a military system corrupted by long peace, a policy without clearness, a diplomacy without honour, had converted the great power founded by Frederick into a body without a soul. There began a new war of which the incidents are almost precisely parallel to those of the war which had so lately closed. As the Austrians at Ulm, so now Napoleon crushed the Prussians at Jena and Auerstädt (October 14) before the appearance of the Russians; as he entered Vienna, so now he enters Berlin (October 27); as he fought a second war in Moravia, in which Austria played a second part to Russia, so now from November 1806 to June 1807 he fights in East Prussia against the Russians aided with smaller numbers by the Prussians; as he might then, after all his successes, have been ruined by the intervention of Prussia, so now, had Austria struck in, he might have found much difficulty in making his way back to France; as at Austerlitz, so at Friedland in June 1807 the Russians ran hastily into a decisive battle

in which they ruined their ally but not themselves; as Austria at Pressburg, so Prussia at Tilsit signed a most humiliating treaty, while Russia, as before, escaped, not this time by simply retiring from the scene, but by a treaty in which Napoleon admitted her to a share in the spoils of victory.

Here was a second catastrophe far more surprising and disastrous than that which it followed so closely. The defeat of Austria in 1805 had been similar to her former defeats in 1800 and 1797; Ulm had been similar to Hohenlinden, the treaty of Pressburg to that of Lunéville. But the double defeat of Jena and Auerstädt, in which the duke of Brunswick, the old general not only of 1792 but of the Seven Years' War, found his death, dissolved for ever the army of the great Frederick; and it was followed by a general panic, surrender of fortresses, and submission on the part of civil officials, which seemed almost to amount to a dissolution of the Prussian state. The defence of Colberg by Gneisenau and the conduct of the Prussian troops under Lestocq at Eylau were almost the only redeeming achievements of the famous army which half a century before had withstood for seven years the attack of three great powers at once. This downfall was expressed in the treaty of Tilsit, which was vastly more disastrous to Prussia than that of Pressburg had been to Austria. Prussia was partitioned between Saxony, Russia, and a newly established Napoleonic kingdom of Westphalia. Her population was reduced by one-half, her army from 250,000 to 42,000 (the number fixed a little later by the treaty of September 1808), and Napoleon contrived also by a trick to saddle her for some time with the support of a French army of 150,000 men. She was in fact, and continued till 1813 to be, a conquered state. Russia on the other hand came off with more credit, as well as with less loss, than in the former campaign. At Eylau in January 1807 she in part atoned for Austerlitz. It was perhaps the most murderous battle that had been fought since the wars began, and it was not a victory for Napoleon. Friedland too was well-contested.

Treaty of Tilsit.

In the two years between August 1805 and the treaty of Tilsit Napoleon had drifted far from his first plan of an invasion of England. But he seemed brought back to it now by another route. England had roused a Coalition against him, which he had not only dissolved, but seemed able now to make impossible for the future. Austria was humbled, Prussia beneath his feet. Why should Russia for the future side with England against him? From the outset her interference in the wars had been somewhat unnecessary; she had had little real interest in the questions of Malta, Naples, or Sardinia. The Russians themselves felt this so much that after Friedland they forced Alexander to make peace. But as Paul, when he left the Second Coalition, had actually joined France, Napoleon now saw the means of making Alexander do the same. England's tyranny of the seas had been attacked by the great Catherine and again by Paul; on this subject therefore Russian policy might co-operate with Napoleon, and, if a bribe were needed, he would countenance her in robbing her ally Prussia, and he could promise her freedom in her eastern enterprises. Such was the basis of the treaty of Tilsit, negotiated between Napoleon and Alexander on an island in the river Niemen, by which treaty the fate of Prussia was decided, and at the same time the foundation of the Napoleonic empire firmly laid. It was a coalition of France and Russia to humble England, chiefly by means of the Continental system. The invasion of England had failed, and England had destroyed at Trafalgar the allied fleets of France and Spain, a defeat which to the public eye had been lost in the splendid triumph of Ulm; but Napoleon now returns to the attack upon England at the head of a universal confederacy which he has organized against her.

A pause occurs after Friedland during which Europe begins slowly to realize her position and to penetrate the character of Napoleon. It took some time to wear out his reputation of peace-maker; at his breach with England in 1803 he had appealed to that jealousy of England's maritime power which was widely spread; many thought the war was forced upon him, and as to the war of 1805 it could not be denied that Austria and Russia had attacked him. His absolute control over the French press enabled him almost to dictate public opinion.

Napoleon as king of kings.

But the conquest of Germany, achieved in little more time than had sufficed to Bonaparte ten years before for the conquest of Italy, put him in a new light. He had already passed through many phases: he had been the invincible champion of liberty, then the destroyer of Jacobinism and champion of order, then the new Constantine and restorer of the church, then the pacificator of the world, then the founder of a new monarchy in France. Now suddenly, in 1807, he stands forth in the new character of head of a great European confederacy. It has been usual to contrast the consulate with the empire, but the great transformation was made by the wars of 1805–7, and the true contrast is between the man of Brumaire and the man of Tilsit. The empire as founded in 1804 did not perhaps differ so much from the consulate after Marengo as both differed, alike in spirit and form, from the empire such as it began to appear after Pressburg and was consolidated after Tilsit. Between 1800 and 1805 Napoleon, under whatever title, was absolute ruler of France, including Belgium, the left bank of the Rhine, Savoy, and Nice, and practically also ruler of Holland, Switzerland, and North Italy to the Adige, which states had a republican form. The title emperor meant in 1804 little more than military ruler. But now emperor has rather its mediæval meaning of paramount over a confederacy of princes. Napoleon has become a king of kings. This system had been commenced in the consulate, when a kingdom of Etruria under the consul's protection was created for the benefit of his ally, the king of Spain; it was carried a stage further on the eve of the war of 1805, when the kingdom of Italy was created, of which Napoleon himself assumed the sceptre, but committed the government to Eugène Beauharnais as viceroy. But now almost all Italy and a great part of Germany is subjected to this system. The Bonaparte family, which before had contended for the succession in France, so that Joseph actually refuses, as beneath him, the crown of Italy, now accept subordinate crowns. Joseph becomes king of Naples, the Bourbon dynasty having been expelled immediately after the peace of Pressburg; Louis becomes king of Holland; Jerome, the youngest brother, receives after Tilsit a kingdom in North Germany composed of territory taken from Prussia, of Hanover, and of the electorate of Hesse-Cassel, which had shared the fall of Prussia; somewhat earlier Murat, husband of the most ambitious of the Bonaparte sisters, Caroline, had received the grand-duchy of Berg. By the side of these Bonaparte princes there are the German princes who now look up to France, as under the Holy Roman Empire they had looked up to Austria. These are formed into a Confederation in which the archbishop of Mainz (Dalberg) presides, as he had before presided in the empire. Two of the princes have now the title of kings, and, enriched as they are by the secularization of church lands, the mediatization of immediate nobles, and the subjugation of free cities, they have also the substantial power. A princess of Bavaria weds Eugène Beauharnais, a princess of Würtemberg Jerome Bonaparte. At its

foundation in 1806 the Confederation had twelve members, but in the end it came to include almost all the states of Germany except Austria and Prussia.

A change seems to take place at the same time in Napoleon's personal relations. In 1804, though the divorce of Josephine was debated, yet it appears to be Napoleon's fixed intention to bequeath his crown by the method of adoption to the eldest son of Louis by Hortense Beauharnais. But this child died suddenly of croup in the spring of 1807, while Napoleon was absent in Germany, and the event occurring at the moment when he attained his position of king of kings probably decided him in his own mind to proceed to the divorce.

It was impossible to give crowns and principalities to the Bonaparte family without allowing a share of similar distinctions to the leading politicians and generals of France. He was therefore driven to revive titles of nobility. To do this was to abandon the revolutionary principle of equality, but Napoleon always bore in mind the necessity of bribing in the most splendid manner the party upon whose support ever since Brumaire he had depended, and which may be described shortly as the Senate. When in 1802 he received the life-consulate, he had proceeded instantly to create new dotations for the senators; now he feels that he must devise for them still more splendid bribes. His first plan is to give them feudal lordships outside France. Thus Berthier, his most indispensable minister, becomes sovereign prince of Neufchatel, Bernadotte sovereign prince of Pontecorvo, Talleyrand sovereign prince of Benevento. Especially out of the Venetian territory, given to France at Pressburg, are taken fiefs (not less than twelve in all), to which are attached the title of duke. These innovations fall in 1806, that is, in the middle of the period of transformation. But after Tilsit, when Napoleon felt more strongly both the power and the necessity of rewarding his servants, he created formally a new noblesse and revived the *majorat* in defiance of the revolutionary code. In the end, besides the three sovereign princes just mentioned, he created four hereditary princes (Berthier is in both lists) and thirty-one hereditary dukes. There were also many counts and barons. The system was prodigiously wasteful. Of public money Berthier received more than £50,000 a year, Davoust about £30,000, nine other officials more than £10,000, and twenty-three others more than £4000.

After Marengo he had seen the importance of reconciling Europe to his greatness by making peace. After Tilsit it was still more urgently necessary that he should dispel the alarm which his conquests had now excited everywhere. But this time he made no attempt to do so; this time he can think of nothing but pushing his success to the destruction of England; and Europe gradually became aware that the evil so long dreaded of a destruction of the balance of power had come in the very worst form conceivable, and that her destiny was in the hands of a man whose headlong ambition was as unprecedented as his energy and good fortune.

As in 1805 he had been drawn into the conquest of Germany in the course of a war with England, so now he assails all the neutral powers, and shortly afterwards violently annexes Spain, not so much from abstract love of conquest as in order to turn against England the forces of all the Continent at once. As he had left Boulogne for Germany, he now, as it were, returns to Boulogne. His successes had put into his hands two new instruments of war against England, instruments none the less welcome because the very act of using them made him master of the whole Continent. He had hinted at the first of these when the war with England began in 1803, by saying that in this war he did not intend that there should be any neutrality; what he meant was explained in 1806 by the edict issued from Berlin. In addition to that limited right which the belligerent has by international law to prevent by blockade the trade of a neutral with the enemy and to punish the individual trader by confiscation of ship and goods, Napoleon now assumed the right of preventing such commerce without blockade by controlling the neutral Governments. English goods were to be seized everywhere, and the harbours of neutrals to be closed against English ships under penalty of war with France. Such a threat, involving a claim to criticize and judge the acts of neutral Governments and to inflict on them an enormous pecuniary fine, was almost equivalent to the annexation at one stroke of all the neutral states. The other instrument had a similar character. The French fleet having been crippled at Trafalgar, he proposed now to reinforce it by all the other fleets in Europe, and to get possession of all the resources of all the maritime states. His eyes therefore become now fixed on Denmark, Portugal, and Spain.

Such is Napoleon as king of kings, and such are his views. This unique phase of European history lasted five years, reckoning from the treaty of Tilsit to the breach with Russia. Europe consists now of a confederacy of monarchical states looking up to a paramount power (like India at the present day). The confederacy is held together by the war with England, which it puts under an ineffective commercial blockade, suffering itself in return a more effective one. But Napoleon feels that Spain and Portugal must be brought under his immediate administration, in order that their maritime resources may be properly turned against England. Austria also has by no means been sufficiently humbled, and Prussia is humbled so intolerably that she is forced into plans of insurrection. Throughout these five years a European party of insurrection is gradually forming. It has two great divisions, one scattered through Germany, at the head of which Austria places herself in 1809, the other in Spain and Portugal, which is aided by England. In Germany this movement is successfully repressed until 1813, but in the Peninsula it gains ground steadily from 1809. After 1812 both movements swell the great Anti-Napoleonic Revolution which then sets in.

Immediately after Tilsit Napoleon entered on his new course, which had been arranged with Russia in secret articles. In August he required the king of Denmark to declare war with England; but here England, seeing herself threatened by a coalition of all Europe at once, interfered with desperate resolution. She required Denmark to surrender her fleet (consisting of twenty ships of the line and a number of frigates) in deposit, promising to restore it at the peace, and when she received a refusal took possession of it by force. At the same time an army is formed under Junot for the invasion of Portugal, with which state, as the old ally of England, Napoleon used no ceremony. The feeble state consented to almost all his demands, agreed to enter the Continental system and to declare war against England; only the regent had a scruple which restrained him from confiscating the property of private Englishmen. From this moment Portugal is doomed, and negotiations are opened with Spain concerning the partition of it. But out of these negotiations grew unexpected events.

For more than ten years Spain had been drawn in the wake of revolutionary France; to Napoleon from the beginning of his reign she had been as subservient as Holland or Switzerland; she had made war and peace at his bidding, had surrendered Trinidad to make the treaty of Amiens, had given her fleet to destruction at Trafalgar. In other states equally subservient, such as Holland and

the Italian Republic, Napoleon had remodelled the government at his pleasure, and in the end had put his own family at the head of it. After Tilsit he thought himself strong enough to make a similar change in Spain, and the occupation of Portugal seemed to afford the opportunity of doing this. By two conventions signed at Fontainebleau on October 27th the partition of Portugal was arranged with Spain. The Prince of the Peace was to become a sovereign prince of the Algarves, the king of Spain was to have Brazil with the title of emperor of the two Americas, &c.; but the main provision was that a French army was to stand on the threshold of Spain ready to resist any intervention of England. The occupation of Portugal took place soon after, Junot arriving at Lisbon on November 30, just as the royal family with a following of several thousands set sail for Brazil under protection of the English fleet. At the same time there commenced in defiance of all treaties a passage of French troops into Spain, which continued until 80,000 had arrived, and had taken quiet possession of a number of Spanish fortresses. At last Murat was appointed to the command of the army of Spain. He entered the country on March 1, 1808, and marched on Madrid, calculating that the king would take flight and take refuge at Seville or Cadiz. This act revealed to the world the nature of the power which had been created at Tilsit. The lawless acts of Napoleon's earlier life were palliated by the name of the French Revolution, and since Brumaire he had established a character for comparative moderation. But here was naked violence without the excuse of fanaticism; and on what a scale! One of the greater states of Europe was in the hands of a burglar, who would moreover, if successful, become king not only of Spain but of a boundless empire in the New World. The sequel was worse even than this commencement, although the course which events took seems to show that by means of a little delay he might have attained his end without such open defiance of law. The administration of Spain had long been in the contemptible hands of Manuel Godoy, supposed to be the queen's lover, yet at the same time high in the favour of King Charles IV. Ferdinand, the heir apparent, headed an opposition, but in character he was not better than the trio he opposed, and he had lately been put under arrest on suspicion of designs upon his father's life. To have fomented this opposition without taking either side, and to have rendered both sides equally contemptible to the Spanish people, was Napoleon's game; the Spanish people, who profoundly admired him, might then have been induced to ask him for a king. Napoleon, however, perpetrated his crime before the scandal of the palace broke out. The march of Murat now brought it to a head. On March 17th a tumult broke out at Aranjuez, which led to the fall of the favourite, and then to the abdication of the king and the proclamation of Ferdinand amid universal truly Spanish enthusiasm. It was a fatal mistake to have forced on this popular explosion, and Napoleon has characteristically tried to conceal it by a supposititious letter, in which he tries to throw the blame upon Murat, to whom the letter professes to be addressed. It warns Murat against rousing the Spanish patriotism and creating an opposition which it will be impossible to put down; it predicts all that actually happened; but it has all the marks of invention, and was certainly never received by Murat. The reign of Ferdinand having thus begun, all that the French could do was to decline to acknowledge him, and to encourage Charles to withdraw his abdication as given under duress. By this means it became doubtful who was king of Spain, and Napoleon, having carefully abstained from taking a side, now presented himself as arbiter. Ferdinand was induced to betake himself to Napoleon's presence at Bayonne, where he arrived on April 21st; his father and mother followed on the 30th. Violent scenes took place between father and son; news arrived of an insurrection at Madrid and of the stern suppression of it by Murat; in the end Napoleon succeeded in extorting the abdication both of Charles and Ferdinand. It was learned too late that the insurrection of Spain had not really been suppressed.

This crime, as clumsy as it was monstrous, brought on that great popular insurrection of Europe against the universal monarchy which has profoundly modified all subsequent history, and makes the Anti-Napoleonic Revolution an event of the same order as the French Revolution. A rising unparalleled for its suddenness and sublime spontaneousness took place throughout Spain and speedily found a response in Germany. A new impulse was given, out of which grew the great nationality movement of the 19th century. Meanwhile Napoleon, having first offered the throne of Spain to his brother Louis, who refused it, named Joseph king, retaining, however, a reversion to himself and heirs in default of male heirs of Joseph, who had only daughters. The royal council first, afterwards a junta of nobles assembled at Bayonne, accepted him on July 7th. But it must have become clear to Napoleon almost at once that he had committed the most enormous of blunders. Instead of gaining Spain he had in fact lost it, for hitherto he had been master of its resources without trouble, but to support Joseph he was obliged in this same year to invade Spain in person with not less than 180,000 men. With Spain too he lost Portugal, which in June followed the Spanish example of insurrection, and had Spain henceforth for an ally and not for an enemy. Hitherto he had had no conception of any kind of war not strictly professional. He had known popular risings in Italy, La Vendée, and Egypt, but had never found it at all difficult to crush them. The determined insurrection of a whole nation of 11,000,000 was a new experience to him. How serious it might be he learned as early as July, when Dupont with about 20,000 men surrendered at Baylen in Andalusia to the Spanish general Castaños. In August he might wake to another miscalculation of which he had been guilty. An English army landed in Portugal, defeated Junot at Vimeiro, and forced him to sign the convention of Cintra. By this he evacuated Portugal, in which country the insurrection had already left him much isolated. This occurrence brought to light a capital feature of the insurrection of the Peninsula, viz., that it was in free communication everywhere with the power and resources of England.

Napoleon in Spain.

Thus the monarchy of Tilsit suffered within a year the most terrible rebuff. Napoleon himself now appears upon the scene. His first step was to revive the memory of Tilsit by a theatrical meeting with Alexander, which was arranged at Erfurt in September. The power of the duumvirate was there displayed in the most imposing manner, and the alliance was strengthened by new engagements taken by Napoleon with respect to the Danubian principalities. At the same time he checked the rising spirit of resistance in Prussia by driving from office the great reforming minister Stein. At the beginning of November he was ready for the invasion of Spain. Joseph had retired to Vittoria, and the armies of the insurrection fronted him along the Ebro under the command of Blake, Castaños, and Palafox. Between November 7th and 11th the army of Blake was dissolved by Lefebvre, and Napoleon entered Burgos, which was mercilessly pillaged; on the 23d Castaños was defeated at Tudela by Lannes; by December 2d Napoleon, having forced the mountain passes, was before Madrid, and on the 4th he was in possession of the town, where, endeavouring somewhat late to conciliate the

liberalism of Europe, he proclaimed the abolition of the Inquisition and of feudalism, and the reduction of the number of convents to one-third. He remained in Spain till the middle of January 1809, but he was not allowed repose during the interval. Sir John Moore had advanced from Portugal as far as Salamanca, and determined in the middle of December to assist the insurrection by marching on Valladolid. Soult was at Carrion and was threatened by this advance, since the English force, after Moore had effected his junction with Baird, who arrived from Corunna, at Majorga, amounted to 25,000 men. Napoleon hoped to cut its communications, and so deal one of his crushing blows at the enemy with whom he was always at war yet whom he never, except at Waterloo, met in the field. He set out on the 22d with about 40,000 men, and marched 200 miles in ten days over mountains in the middle of winter. Moore saw the danger, retired to Benavente, and blew up the bridges over the Ezla. Napoleon advanced as far as Astorga; but he had missed his mark, and professed to receive information which showed him that he was urgently wanted at Paris. He returned to Valladolid, whence on January 19th he set out for France. The end of Moore's expedition belongs to English history.

Another storm was indeed gathering. The downfall of Austria in 1805 had been out of all proportion to her military inferiority; it was impossible that she should acquiesce in it. The year that followed Tilsit had given her quite a new prospect. Spain, which before had given Napoleon help, now swallowed up 300,000 of his troops, so that in the autumn of 1808 he had been obliged to withdraw from Prussia the large army which he had kept for more than a year quartered on that unhappy country. Napoleon could now spare only half his force, and there was now no doubt that Prussia would be as hostile to him as she dared. True, the army of Frederick had ceased to exist, but the country was full of soldiers who had belonged to it, full of skilled officers, and Spain had filled all minds with the thought of popular war. Stein and Scharnhorst had been preparing a *levée en masse* in Prussia and an insurrection in the new kingdom of Westphalia. Under such circumstances began the war of 1809, which may be called the First German War of Liberation, under the leadership of Austria. It was provoked rather by Napoleon, who wanted new victories to retrieve his position, than by Austria, whose interest lay in gaining time, since time was likely to increase the ferment in Germany and weaken the alliance of Napoleon and Russia. Napoleon's superiority, though on the wane, was still enormous. Through the Confederation of the Rhine he had now a great German army at his disposal, which he placed under French generals. His frontier was most formidably advanced through the possession of Tyrol and Venetia. Russia was on his side, and, though she did not actively help him in the field, was of great use in holding down Prussia; England was against him, but could do little for an inland state such as Austria now was. In these circumstances the attitude of Austria had something heroic about it, like that of Spain, and the war throughout is like a somewhat pale copy of the Spanish insurrection. But Austria has what Spain had not, the advantage of organization and intelligence. Since Pressburg she had passed through a period of reform and shown some signs of moral regeneration, Stadion and the archduke Charles doing for her, though not so effectively, what Stein and Scharnhorst did for Prussia. Few wars have begun with less ostensible ground, or more evidently from an intolerable position. Napoleon accused Austria of arming, of wanting war; Austria expostulated, but in vain; and war began. It began early in April, and the proclamation of the archduke Charles was addressed to the whole German nation. The watchword of Austria against France was now liberty and nationality. A good general conception of the war may be obtained by comparing it with that of 1805, which it resembles in certain large features. Again there is a short but decisive passage of arms in Bavaria; in a five days' struggle, celebrated for Napoleon's masterly manœuvres, the Austrians are driven out of Ratisbon, and the way to Vienna is laid open. Again Napoleon enters Vienna (May 13th). But the war in Italy this time begins farther east, on the Piave. Eugène Beauharnais, after an unfortunate commencement when he was defeated at Sacile by the archduke John makes a successful advance, and being joined by Marmont, who makes his way to him from Dalmatia by way of Fiume, drives the Austrian army into Hungary, defeats them at Raab, and effects a junction with Napoleon at Bruck. Then, as before, the war is transferred from Vienna to the other side of the Danube. But the Austrian resistance is now far more obstinate than in 1805. From the island of Lobau Napoleon throws his troops across the river in the face of the archduke. A battle takes place which occupies two successive days, and is sometimes called the battle of the Marchfeld, but is sometimes named from the villages of Gross-Aspern and Essling. Like that of Eylau in 1807 it is among the most terrible and bloody battles of the period. In all perhaps 50,000 men fell, among whom was Marshal Lannes, and the French were driven back into their island. Five weeks passed in inaction before Napoleon could retrieve this check, five weeks during which the condition of Europe was indeed singular, since its whole destiny depended upon a single man, who, besides the ordinary risks of a campaign, was threatened by an able adversary who had recently brought him to the verge of destruction, and by outraged populations which might rise in insurrection round him. This is the moment of the glory of Hofer, the hero of the peasant-war in Tyrol. Once more, however, Napoleon's skill and fortune prevailed. On the night of July 4th he succeeded, under cover of a false attack, in throwing six bridges from Lobau to the left bank of the Danube, over which more than 100,000 men passed before morning and were arrayed upon the Marchfeld. The obstinate battle of Wagram followed, in which, by a miscalculation which became the subject of much controversy, the archduke John came too late to his brother's help. The Austrians were worsted, but by no means decisively, and retired in good order.

Battle of Wagram.

Austerlitz and Friedland had led at once to peace, because the principal belligerent, Russia, had little direct interest in the war; Wagram ought to have had no similar effect. Austria was engaged in a war of liberation; Tyrol was emulating Spain; there should therefore have been no negotiation with the invader. But Germany had as yet but half learnt the Spanish principle of war; in particular the Austrian Government and the archduke Charles himself belonged to Old Austria rather than to New Germany. In the campaign the archduke had fallen much below his reputation, having allowed it plainly to appear that Napoleon frightened him, and now, instead of appealing again to German patriotism, he signed at Znaim (July 11th) an armistice similar to that which Melas had so unaccountably concluded after Marengo. But it was by no means certain that all was yet over. North Germany might rise as Spain had risen and as Tyrol had risen. The archduke Ferdinand had marched into Poland and threatened Thorn, with the intention of provoking such a movement in Prussia, and England was preparing a great armament which the patriots of North Germany, who now began to emulate the Spanish guerilla leaders,—Schill,

Dörnberg, Katt, Brunswick,—anxiously expected. There seems little doubt that, if this armament had made Germany its object, Germany would at once have sprung to arms and have attempted, perhaps prematurely, what in 1813 it accomplished. What was expected in Germany had happened already in the Peninsula. Arthur Wellesley had landed at Lisbon on April 22d, and in less than a month had driven Soult in confusion out of Portugal. In July he undertook an invasion of Spain by the valley of the Tagus. Thus both the quantity and quality of resistance to Napoleon was greater than at any former time; but it was scattered, and the question was whether it could concentrate itself.

But England was unfortunate this time in her intervention. The armament did not set sail till August, when in Austria the war seemed to be at an end, and when Wellesley, after winning the battle of Talavera, had seen himself obliged to retire into Portugal, and it was directed not to Germany but against Antwerp. It was therefore a mere diversion, and as such it proved unsuccessful. It created indeed a great flutter of alarm in the administration at Paris, which saw France itself left unprotected while its armies occupied Vienna and Madrid, but by mismanagement and misfortune the great enterprise failed, and accomplished nothing but the capture of Flushing.

Treaty of Schönbrunn.

And so the last triumph of Napoleon was achieved, and the treaty of Schönbrunn was signed on October 20th. By this treaty, as by former treaties, he did not merely end a war or annex territory, but developed his empire and gave it a new character. He now brought to an end the duumvirate which had been established at Tilsit. Since Tilsit his greatness had been dependent on the concert of Russia. He had had the czar's permission to seize Spain, the czar's co-operation in humbling Austria. Schönbrunn made his empire self-dependent and self-supporting, and thus in a manner completed the edifice. But he could not thus discard Russia without making her an enemy, and accordingly the Russian war appears on the horizon at the very moment that the Austrian war is terminated. This transformation was accomplished by first humbling Austria, and then, as it were, adopting her and giving her a favoured place in the European confederacy. She lost population to the amount of 3,500,000, besides her access to the sea; she paid an indemnity of more than £3,000,000, and engaged to reduce her army to 150,000. But, thus humbled, a high and unique honour was reserved for her. We cannot be quite certain whether it was part of Napoleon's original plan to claim the hand of an archduchess, though this seems likely, since Napoleon would hardly break with Russia unless he felt secure of the alliance of Austria, and yet in the treaty of Schönbrunn he does not hesitate to offend Russia by raising the Polish question. What is certain is that after his return to France Napoleon proceeded at once to the divorce, that at the same time he asked the czar for the hand of his sister, that upon this Austria, alarmed, and seeing her own doom in the Russian match, gave him to understand (as he may very well have calculated that she would do) that he might have an archduchess, and that upon this he extricated himself from his engagement to the czar with a rudeness which might seem intended to make him an enemy. At the same time he refused to enter into an engagement not to raise the Polish question.

War with Russia impending.

Divorce of Josephine.

At an earlier period we saw Napoleon urged by his brothers to divorce Josephine, but refusing steadfastly and apparently resolved upon adopting the eldest son of Louis and Hortense. He had now quite ceased to be influenced by his brothers, but at the same time he had risen to such greatness that he had himself come to think differently of the question. Fourteen years before he had been warmly attached to Josephine; this attachment had been an effective feature in the character of republican hero which he then sustained. Mme. de Staël had been profoundly struck, when, on being charged by her with not liking women, he had answered, "J'aime la mienne." "It was such an answer," she said, "as Epaminondas would have given!" He is now equally striking in the part of an Oriental sultan, and when he discards his Josephine for ambition he requires to be publicly flattered for his self-sacrifice by the officials, by Josephine herself, and even by her son Eugène Beauharnais!

Marriage with Marie Louise.

The archduchess Marie Louise, who now ventured to take the seat of Marie Antoinette, seems to have been of amiable but quite insignificant character. Her letters are childlike. She became a complete Frenchwoman, but, owing to a certain reserve of manner, was never specially popular. On March 20, 1811, she bore a son, who took the title of King of Rome, by which in the Holy Roman Empire the successor had been designated. France had thus become once more as monarchical as in the proudest days of Versailles; but the child of empire was reserved for what his father called "the saddest of fates, the fate of Astyanax."

Arrived now at the pinnacle, Napoleon pauses, as he had paused after Marengo. We are disposed to ask, What use will he now make of his boundless power? It was a question he never considered, because the object he had set before himself in 1803 was not yet attained; he was not in the least satiated, because, much as he had gained, he had not gained what he sought, that is, the humiliation of England. As after Tilsit, so after Schönbrunn, he only asks, How may the new resources be best directed against England? Yet he did not, as we might expect, devote himself to crushing the resistance of the Peninsula. This he seems to have regarded with a mixed feeling of contempt and despair, not knowing how to overcome it, and persuading himself that it was not worth a serious effort. He persisted in saying that the only serious element in the Spanish opposition was the English army; this would fall with England herself; and England, he thought, was on the point of yielding to the blockade of the Continental system. He devotes himself henceforth therefore to heightening the rigour of this blockade. From the beginning it had led to continual annexations, because only Napoleon's own administration could be trusted to carry it into effect. Accordingly the two years 1810–11 witness a series of annexations chiefly on the northern sea-coast of Europe, where it was important to make the blockade more efficient. But on this northern sea-coast lay the chief interests of Russia. As therefore in 1805 he had brought Austria and Russia on himself by attacking England, so in 1810 he presses his hostility to England to the point that it breaks the alliance of Tilsit and leads to a Russian war.

Annexation of Holland and Westphalia.

The year 1810 is occupied with this heightening of the Continental system and the annexations which it involved. That he had long contemplated the annexation of Holland appears from the offer of the crown of Spain which he made to Louis in 1808, and the language he then used ("La Hollande ne saura sortir de ses ruines"). He now took advantage of the resistance which Louis made to his ruinous exactions. Louis was driven to abdicate, and the country was organized in nine French departments. In August the troops of the king of Westphalia were forced to make way for French troops at the mouths of the Elbe and Weser, and a few months later the whole coast between the Rhine and the Elbe was annexed. At the same time Napoleon began to make war on neutral commerce, especially American, affirming that in order to complete the destruction of English trade it was only necessary to prohibit it when it made use of neutral bottoms. So

thoroughly in earnest was he with his Continental system; and indeed it is beyond dispute that great distress and discontent, nay, at last a war with the United States, were inflicted upon England by this policy.

issolu-on of ie alli-nce of ilsit.

But the pressure of it was felt even more on the Continent, and the ultimate cause of the fall of Napoleon was this, that under the weight of the Continental system the alliance of Tilsit broke down sooner than the resistance of England. That alliance had been seriously weakened by the Austrian marriage, and by Napoleon's refusal to give the guarantees which Russia required that Poland should never be restored. Indeed Napoleon had seemed to take pleasure in weakening it, but perhaps he had only desired to make it less burdensome to himself without destroying it. At the end of 1810 measures were taken on both sides which conveyed the impression to Europe that it was practically at an end. Alexander refused to adopt Napoleon's policy towards neutrals; Napoleon answered by annexing Oldenburg, ruled by a duke of the Russian house; Alexander rejoined by an ukase (December 31st) which modified the restrictions on colonial trade and heightened those on French trade.

nvasion of Russia.

In 1811 the alliance of Tilsit gradually dissolves. Napoleon's Russian expedition is hardly to be regarded as a freak of insane pride. He himself regarded it as the unfortunate effect of a fatality, and he betrayed throughout an unwonted reluctance and perplexity. The truth is, he could not now stop. Upon the Continental system he had staked everything. He had united all Europe in the crusade against England, and no state, least of all such a state as Russia, could withdraw from the system without practically joining England. Nevertheless we may wonder that, if he felt obliged to make war on Russia, he should have chosen to wage it in the manner he did, by an overwhelming invasion. For an ordinary war his resources were greatly superior to those of Russia. A campaign on the Lithuanian frontier would no doubt have been unfavourable to Alexander, and might have forced him to concede the points at issue. Napoleon had already experienced in Spain the danger of rousing national spirit. It seems, however, that this lesson had been lost on him, and that he *still* lived in the ideas which the campaigns of 1805, 1806, and 1807 had awakened, when he had occupied Vienna and Berlin in succession, overthrown the Holy Roman Empire, and conquered Prussia. He makes a dispute about tariffs the ground of the greatest military expedition known to authentic history! In this we see a stroke of his favourite policy, which consisted in taking with great suddenness a measure far more decisive than had been expected; but such policy seems here to have been wholly out of place. He was perhaps partly driven to it by the ill-success of his diplomacy. War with France meant for Russia sooner or later alliance with England, but Napoleon was not able to get the help of Turkey, and Sweden joined Russia. Turkey had probably heard of the partition-schemes which were agitated at Tilsit, and was also influenced by the threats and promises of England. Sweden suffered grievously from the Continental system, and Bernadotte, who had lately become crown prince, and who felt that he could only secure his position by procuring for Sweden some compensation for the recent loss of Finland, offered his adhesion to the power which would help him in acquiring Norway. Napoleon declined to rob his ally, Denmark, but Alexander made the promise, and Sweden was won. Against Russia, Sweden, and England (a coalition which formed itself but tardily) Napoleon assembled the forces of France, Italy, and Germany, and hoped to win, as usual, by the rapid concentration of an overwhelming force. The army with which he invaded Russia consisted of somewhat more than 600,000 men,—the French troops mainly commanded by Davoust, Oudinot, and Ney, the Italian troops by Prince Eugene, the Poles by Poniatowski, the Austrian contingent (33,000 men) by Schwarzenberg, the remaining German troops by Gouvion St Cyr, Reynier, Vandamme, Victor, Macdonald (who had the Prussian contingent), and Augereau. When we consider that the war of the Peninsula was at the same time at its height, and that England was now at war with the United States, we may form a notion of the calamitous condition of the world!

Russia had been easily defeated at Austerlitz and Friedland, where it fought far from home for a cause in which it was but slightly interested. Against an invasion it was as invincible as Spain, being strengthened by a profound national religion and perfect loyalty to the Government; in addition it had the strength of its vast extent, its rigorous climate, and the half-nomad habits of its people. By his prodigious preparations Napoleon provoked a new national war under the most difficult circumstances, and yet he appears to have desired peace and to have advanced most reluctantly. His campaign runs the same course as against Austria in 1805 and 1809. There is the successful advance, the capture of the fortress (Smolensk), the great victory (at Borodino), the entry into the capital (Moscow); but of all this no result. No negotiation follows, and Napoleon suddenly finds himself helpless, as perhaps he would have done in 1805 and 1809, had the enemy shown the same firmness. On May 16, 1812, he arrived with Marie Louise at Dresden, where for the last time he appeared as king of kings,—the emperor of Austria, the king of Prussia, a multitude of German sovereigns, Metternich, and Hardenberg paying court to him. On the 28th he set out again and travelled by Glogau, Thorn, Dantzic, Königsberg, Gumbinnen, to Wilkowyski, where he arrived on June 21st. On the 24th the mass of the army passed the Niemen at Kovno, and on the 28th Napoleon entered Vilna, which was evacuated by the Russians. Here he remained till July 16th. In this long delay, as well as in other circumstances, the unwonted perplexity of his mind appears. Alexander, who has by this time gained greatly in decision of character, refuses to negotiate while the enemy stands on Russian territory; Napoleon in conversation with Balacheff shows an almost pathetic desire for an amicable arrangement. He is embarrassed again when a deputation from Warsaw, where a diet had met, bids him only say that "*Poland exists*, since his decree would be for the world equivalent to the reality." This word he declines to say, alleging his obligations to Austria. From his conversations with Narbonne (Villemain, *Souvenirs*) we find that he had deliberately considered and rejected what we may call the rational mode of waging war with Russia, that is, through the restoration of Poland. He admitted that he might indemnify Austria and, if necessary, Prussia elsewhere, but he argued that he could not afford to open the floodgates of republicanism: "Poland must be a camp, not a forum." He had in fact—perhaps mainly since his second marriage—come to regard himself as the representative of legitimacy against the Revolution. It was thus with his eyes open that he preferred the fatal course of striking at Moscow. His judgment was evidently bewildered by the successes of 1805 and 1806, and he indulges in chimerical imaginations of delivering Europe once for all from the danger of barbaric invasion. It is to be observed that he seems invariably to think of the Russians as Tartars!

In relating this war we have to beware of national exaggerations on both sides. On Napoleon's side it is absurdly said that he was only vanquished by winter, whereas it is evident that he brought the winter upon

himself, first by beginning so late, then by repeated delays, at Vilna, at Vitebsk, and most of all at Moscow. On the other side we must not admit absolutely the Russian story that he was lured onward by a Parthian policy, and that Moscow was sacrificed by a solemn universal act of patriotism. Wellington's policy of retrograde movements had indeed come into fashion among specialists, and an entrenched camp was preparing at Drissa on the Dwina in imitation of Torres Vedras. But the nation and the army were full of reckless confidence and impatience for battle; only their preparations were by no means complete. The long retreat to Moscow and beyond it was unintentional, and filled the Russians with despair, while at the same time it agreed with the views of some of the more enlightened strategists.

As usual, Napoleon took the enemy by surprise, and brought an overwhelming force to the critical point. When he crossed the Niemen the Russians were still thinking of an offensive war, and rumours had also been spread that he would enter Volhynia. Hence their force was divided into three armies: one, commanded by the Livonian Barclay de Tolly, had its headquarters at Vilna, a second under Prince Bagration was further south at Volkowysk, the third under Tormasoff was in Volhynia. But the total of these armies scarcely amounted to 200,000 men, and that of Barclay de Tolly opposed little more than 100,000 to the main body of Napoleon's host, which amounted nearly to 300,000. Hence it evacuates Vilna and retires by Svenziany to the camp at Drissa. Barclay arrives at Drissa on July 9th, and here for the first time the emperor and the generals seem to realize the extent of the danger. Alexander issues an ukase calling out the population in the proportion of five to every hundred males, and hurries to Moscow and thence to St Petersburg in order to rouse the national enthusiasm. The Drissa camp is also perceived to be untenable. It had been intended to screen St Petersburg, and Napoleon is seen to look rather in the direction of Moscow. Barclay retires to Vitebsk, but is obliged, in order to effect his junction with Bagration, to retreat still further, and Napoleon enters Vitebsk on the 28th. The road to Moscow passes between the Dwina, which flows northward, and the Dnieper, which flows southward. Vitebsk on the one river and Smolensk on the other forming, as it were, the two doorposts. We expect to find Napoleon at this point cutting the hostile armies in two and compelling that of Bagration to a surrender: he has a great superiority of numbers, and he might have had the advantage of a friendly population. But his host seems unmanageable, and the people are estranged by the rapacity and cruelty to which it is driven by insufficient supplies. Barclay and Bagration effect their junction at Smolensk on August 3d, and now have a compact army of at least 120,000 men. They evacuated Smolensk also on the 18th, but only after an obstinate defence which left Napoleon master of nothing but a burning ruin.

Both at Vitebsk and Smolensk he betrayed the extreme embarrassment of his mind. Should he go into winter quarters? should he press forward to Moscow? It was a choice of desperate courses. His army was dwindling away; he had forfeited the support of the Poles; Germany was full of discontent; and yet a large part of his army was Polish or German; how could he delay? And yet if he advanced, since August was already running out, he must encounter the Russian winter. He determined to advance, relying on the overwhelming effect that would be produced by the occupation of Moscow. He would win, as after Austerlitz and Friedland, through the feebleness and fickleness of Alexander.

Meanwhile his unresisted progress, and the abandonment by Barclay of one position after another, created the greatest consternation among the Russians, as well they might. Barclay was a German, and might well seem another Melas or Mack. A cry arose for his dismissal, to which the czar responded by putting old Kutusoff, who was at least a Russian, at the head of all his armies. This change necessarily brought on a great battle, which took place on September 6th near the village of Borodino. More than 100,000 men and about six hundred pieces of artillery were engaged on each side. It ended in a victory, but an almost fruitless victory, for the French. They lost perhaps 30,000 men, including Generals Montbrun and Caulaincourt, the Russians nearly 50,000, including Prince Bagration. Here again Napoleon displayed unwonted indecision. He refused to let loose his guard, consisting of 20,000 fresh troops, who might apparently have effected the complete dissolution of the hostile army, and materially altered the whole sequel of the campaign. He said, "At 800 leagues from Paris one must not risk one's last reserve."

Battle of Borodino.

This battle, the greatest after Leipsic of all the Napoleonic battles, was followed by the occupation of Moscow on September 14, which, to Napoleon's great disappointment, was found almost entirely empty. After a council of war held at Fili, Kutusoff had taken the resolution to abandon the old capital, the loss of which was held not to be so irreparable as the loss of the army. But, as with Old Russian craft he had announced Borodino to the emperor as a victory, the sensation produced upon the Russian public by the fall of Moscow was all the more overwhelming. Nor did the next occurrence, which immediately followed, at first bring any relief. Fires broke out in Moscow on the night after Napoleon's entrance; on the next night, by which time he was quartered in the Kremlin, the greater part of the city was in flames, and on the day following he was forced by the progress of the conflagration to evacuate the Kremlin again. But on the first intelligence of this catastrophe the destruction of Moscow was attributed in Russia to the French themselves, and was not by any means regarded as a crushing blow dealt at Napoleon by Russian patriotism.

Burning of Moscow

It is indeed not clear that this event had any decisive influence upon the result of the war. Nor does it seem to have been the deliberate work of the patriotism of Moscow. The beginner of it was one man, Count Rostopchin, governor of Moscow, who is shown by many public utterances to have brooded for some time over the thought, and is proved to have made preparations for carrying it into effect before leaving the town. It is, however, supposed that what was begun by him was completed by a rabble which had no object but plunder, and partly by French soldiers. The immediate effect of it was to deepen the alarm of the Russians, and, when this feeling passed away, to deepen their hatred of the French. Now came the critical moment. Would Alexander negotiate? That is, would he listen to certain timid courtiers about him, such as Romanzoff, or would he be inspired by the patriotic ardour of his people and lean on his nobler counsellors, the German patriot Stein or Sir Robert Wilson? The pressure for a moment was great; we can imagine that had the Russian army been dissolved at Borodino it might have been irresistible. But he stood firm; he refused to negotiate; and Napoleon suddenly found that he had before him, not the simple problem he had solved so often in earlier life, but the insoluble puzzle he had first encountered in Spain. His failures in Egypt and in Spain had been more or less disguised. He was now in danger of a failure which could not be concealed, and on a far larger scale; but had he retreated forthwith and wintered in Vilna, where he might have arrived early in November, the conquest of Russia might have seemed

only to be postponed for a year. Instead of this he delayed five weeks in Moscow, and then complained of the Russian winter! After planning a demonstration on St Petersburg, weighing Daru's scheme of wintering in Moscow (which he called "un conseil de lion"), and waiting in vain for the czar's submission, he set out on October 18th after blowing up the Kremlin. He marched southward to Kaluga, hoping to make his way through a richer and unexhausted country. But while his force had dwindled the Russian had increased. Peace with Sweden had released a Russian force in Finland; peace with Turkey released the army of the Danube; meanwhile levies were proceeding through the whole empire. Napoleon's plan was frustrated by a check he received at Malojaroslavetz, and he had to turn northward again and return as he had come. He reached Smolensk on November 9th, when he might have been at Vilna. He marched by Orcza to the Berezina, which he struck near Borisoff. Here Tchitchagoff at the head of the Danube army confronted him, and two other Russian armies were approaching. Napoleon on his side was joined by what remained of the corps of Oudinot and Victor, who had held the line of the Dwina. But what was the army of Napoleon which was thus reinforced?

etreat om Ioscow.

In July it had consisted of more than 250,000 men. It had suffered no decisive defeat, and yet it amounted now only to 12,000; in the retreat from Moscow alone about 90,000 had been lost. The force which now joined it amounted to 18,000, and Napoleon's star had still influence enough to enable him to make his way across the Berezina, and so escape total ruin and captivity. But December came on, and the cold was more terrible than ever. On the evening of December 6th a miserable throng, like a crowd of beggars, tottered into Vilna.

The corps of Macdonald, Reynier, and Schwarzenberg (among whom were included the Austrian and Prussian contingents) had escaped destruction, having been posted partly on the Polish frontier partly in the Baltic provinces. For these we may deduct 100,000 from the total force; it then appears that half a million had perished or disappeared. They had perished not by unexpected cold; "the cold had but finished the work of dissolution and death almost accomplished by the enemy, by hardship, and especially by hunger" (Charras); nor is cold unusual in Russia in November! Napoleon's error was one which may be traced as clearly in the campaigns of 1805 and 1806, the error of making no provision whatever for the case of ill-success or even success less than complete. It was now the twentieth year that Europe was tearing itself to pieces. For some years past the pretence of Revolutionary principles had been given up. There was now no pretext for war except the so-called maritime tyranny of England; but yet the magnitude of wars had increased beyond all measurement. The campaign of 1812 left everything in civilized history far behind it. All the abuses of the old monarchy and all the atrocities of the Revolution put together were as nothing compared to this new plague, bred between the Revolution and the old monarchy, having the violence of the one and the vainglory of the other, with a barbarous destructiveness peculiar to imperialism superadded.

But what was Napoleon's position? Any Government but the strongest would have sunk under such a blow, but Napoleon's Government was the strongest, and at its strongest moment. Opposition had long been dead; public opinion was paralysed; no immediate rising was to be feared. Should he then simply take the lesson home, and make peace with Alexander? This was impossible; he must efface the disaster by new triumphs. But, as this was evident to all, Alexander could not but perceive that he must not lose a moment, but must hasten forward and rouse Germany before Napoleon should have had time to levy a new army. 1813 must be filled with a war in Germany, as 1812 with the war in Russia.

Napoleon left the wreck of his army at Smorgoni on December 5 (as he had left his Egyptian army thirteen years before), travelling in a carriage placed upon a sledge and accompanied by Caulaincourt and Duroc. He had an interview with Maret outside Vilna, and then travelled to Warsaw, where he saw his ambassador De Pradt, who has left an account of his confused talk. Here, as in the famous 29th bulletin, published a little after, we observe that he consoles himself for the loss of his army by reflecting that his own health was never better—he kept on repeating this. Then he said, "From the sublime to the ridiculous there is but a step"; for the retreat from Moscow strikes him as *ridiculous*! From Warsaw he passed to Dresden, where he saw his ally the king of Saxony, and wrote letters to the emperor of Austria and to the king of Prussia. He then made his way by Erfurt and Mainz to Paris, where he arrived on December 18th. The bulletin had appeared two days before.

He had said to De Pradt that he intended to raise 300,000 men and be on the Niemen again in the spring. The first part of this intention he fulfilled, for in April he reappeared in the field with 300,000 men; but the campaign was fought not on the line of the Niemen, nor of the Vistula, nor of the Oder, and he had to fight a battle before he could even reach the Elbe. For a great event took place less than a fortnight after his arrival in Paris, the defection of the Prussian contingent under York from the grand army; this event led to the rising of Prussia against Napoleon. York's convention with the Russians is dated December 30th. On January 22, 1813, Stein appeared at Königsberg and procured the assembling of the estates of East Prussia, in which assembly the Prussian landwehr was set on foot. On February 27th he concluded for the czar the treaty of Kalisch with Prussia, by which the old Coalition of 1806 may be said to have been revived. Prussia now rushed to arms in a wholly new spirit, emulating Spain and Russia in devotion, and adding to devotion an intelligence peculiar to herself. At the same time measures were taken to break up the Confederation of the Rhine. Tettenborn cleared the French out of the northern departments in March; Saxony too passed into the hands of the allies, and it was hoped that the king himself might be induced to follow the example of the king of Prussia. But April came, and Napoleon took the field again.

Wars 1813-

By rapidity and energy he was still able to take the offensive. Though Russia and Prussia were now as Spain, yet the process of calling out and drilling their population was only just begun, and it proceeded slowly. Their united available force at the opening of the campaign scarcely exceeded 100,000 men. Austria and the middle states did not abandon Napoleon. With tact and with judicious concession he might yet retrieve his position; perhaps no one, as yet, had begun to think of his fall. He left Paris for Mainz on April 15th. His object was Saxony, where Dresden, the scene of his last display of omnipotence less than a year ago, was now the residence of the czar and the king of Prussia united against him. Eugene was maintaining himself on the lower Saale with an army of about 70,000 men, and Napoleon was to march by way of Erfurt to join him. Between Erfurt, Bamberg, and Mainz he had by this time about 150,000 men, troops indeed without discipline and with imperfect drill, youths, the last hope of France, but well officered and not wanting in the enthusiasm which his name still inspired. There was, however, a serious deficiency of cavalry. Mean-

while Davoust, stationed on the Weser with 30,000 men, was holding down the insurrection of North Germany.

The war which now commenced ended not only to the disadvantage of Napoleon, but unlike any former war it ended in a complete defeat of France, nay, in the conquest of France, an event to which nothing parallel had been seen in modern Europe. Nor was this result attained by any political or revolutionary means, *e.g.*, by exciting a republican or Bourbon party against Napoleon's authority, but by sheer military superiority. The causes of this remarkable result must be noted as we proceed. Meanwhile we remark that the war, though technically one, is really three distinct wars. There is first the war with Russia and Prussia which occupies the month of May, and is concluded by an armistice on June 4th. There is next a war with Russia, Prussia, and Austria, which begins in August and is practically terminated in October by the expulsion of Napoleon from Germany. Thirdly, there is an invasion of France by the same allied powers. This began in January 1814, and ended in April with the fall of Napoleon.

War with Russia and Prussia.

In the first of these wars Napoleon maintained on the whole his old superiority. It has excited needless admiration that with his raw levies he should still have been able to win victories, since of his two enemies Russia had suffered as much as himself in 1812, and Prussia's army was at the beginning of the year actually to make. In the first days of May he advanced down the valley of the Saale, making for Leipsic by Naumburg, Weissenfels, and Lützen. On the 2d was fought the battle commonly called from Lützen, though the Germans usually name it from the village of Gross-Görschen. By this battle, in which the great military reformer of Prussia, Scharnhorst, received the wound of which he died soon after, the allies were driven to retreat across the Elbe, and Dresden was restored to the king of Saxony. The Prussians attribute their ill-success partly to the insufficiency of the Russian commander Wittgenstein, under whom they fought. Napoleon soon pursued the allies across the Elbe, and another battle was fought on May 20 and 21 at Bautzen on the Spree. Here again Napoleon remained master of the field, though his loss seems to have been considerably greater than that of the enemy. The allies retired into Silesia, and a pause took place, which led to the armistice of Poischwitz, signed on June 4th. During this armistice Napoleon formed the resolution which led to his downfall.

He might seem now to have almost retrieved his losses. If he could not revive the great army of the Revolution which lay buried (or unburied) in Russia, he had reasserted the ascendency of France. Politically he had suffered but one substantial loss, in the rebellion of Prussia. The blows of Lützen and Bautzen had arrested the movement which threatened to dissolve the Confederation of the Rhine and to unite all Germany against him. They had also shaken the alliance of Prussia and Russia. Between the generals of the two armies there reigned much jealousy; the old question, raised after Austerlitz and Friedland, was beginning to be asked again by the Russians, Why should they fight for others?

Relations to Austria.

At Tilsit Napoleon had dissolved the Coalition by forming as it were a partnership with Russia. It might seem possible now to form a similar partnership with Austria. This course had indeed been entered upon at the marriage of the archduchess. Napoleon seems to have taken this alliance seriously. He conceived it as the final suppression of the Revolution, as a complete adhesion on his own part to conservatism. The language of the bulletins at this time is ultra-conservative. Thus the enemy is described as "preaching anarchy and insurrection." Stein is charged with "rousing the rabble against the proprietors." But, though he had borrowed the Austrian tone, he had not yet enlisted Austrian interests on his side. It was evidently in his power to confer on Austria the greatest advantages, and, as it were, to divide his power with her. Less than this he could not offer, since the losses of France and Russia had given to Austria a decisive weight, but it might seem that he might offer it without much humiliation, as the alliance with Austria had subsisted since 1810 and had been cemented by marriage. If he did not thus win Austria, he might expect her to adhere to the other side, for in such a crisis neutrality was out of the question. Could Napoleon then hope to overcome a quadruple alliance of England, Russia, Prussia, and Austria? Such a hope was not justified by the victories of Lützen and Bautzen. The force of Prussia increased every day, and the Spanish enthusiasm with which her new army fought had been displayed even on those fields; the force of Austria had been impaired by no Russian campaign; while France was evidently near the end of her resources. The legerdemain by which, in 1800, 1805, 1806, Napoleon had made conquests was now worn out; his blows were no longer followed by abject submission and surrender; he was not even able, for want of cavalry, to make his victories decisive. Thus ample concessions to Austria were indispensable; but, these assumed, his position might seem good.

He took the momentous resolution to make no such concessions, saw Austria join the Coalition, and after a campaign of two months found himself driven in tumultuous ruin across the Rhine. This step is the counterpart of Tilsit, and destroyed the work of Tilsit. Was he simply blinded by passion? His language might lead us to think so. Austria was the state which he had oftenest defeated, and he seems to have been unable to regard it with the respect which he had shown to Russia at Tilsit. From the beginning of 1813 we find him calculating indeed on the help of Austria, and fully recognizing the importance of her alliance, yet indignant at the very thought of having to pay for it. He would prefer to make advances to his enemy Russia rather than give his ally Austria any equality with himself in the alliance. Austria on her part seems disposed to be faithful to him. She begins by adhering to the substance of her treaty of March 1812, but requiring certain modifications in it. Napoleon must withdraw from north-west Germany, dissolve the duchy of Warsaw, cede Illyria, perhaps also dissolve the Confederation of the Rhine. But on the last point she might probably have given way, so that Napoleon, already victorious against Russia and Prussia, might now, without yielding any substantial part of his power, have checkmated another Coalition by the help of Austria. Nevertheless it seems as if Napoleon, though this course was open to him for several months, was not for a moment attracted by it, though the clamour for peace which his own army and his own marshals raised compelled him to profess to take it into consideration. He continued deliberately to contemplate in preference a war against Russia, Prussia, and Austria united, and regarded the armistice simply as a delay which would enable him to bring up new forces. Austria on her part was gradually convinced that no concession was to be obtained from him, and drifted towards the decisive resolution which she could not avoid. Metternich has left us an account of the interview, lasting ten hours, which he had with Napoleon on June 28, in the Marcolini palace at Dresden. We see in it Napoleon's contempt for a power he has so often defeated, his inability to believe that it has still spirit to resist; at the same time we become aware that he believes himself to be necessary to the Austrian emperor, as being the bulwark of all thrones and of monarchy itself against

the Revolution. Metternich can hardly have imagined the famous dramatic trait where Napoleon, on being told that his troops were "not soldiers, but children," answered, turning pale—"You are no soldier; you do not know what passes in a soldier's mind; I grew up in the field, and a man like me troubles himself little about the life of a million of men" (the actual expression he used, adds Metternich, cannot be reported), and then flung his hat into a corner of the room. That this was a true description of his way of thinking had become visible to most since the Russian catastrophe, and the audacious frankness with which he blurts it out is quite in his characteristic manner.

When this interview took place, a treaty had just been signed at Reichenbach by which Austria had engaged, as mediating power, formally to offer conditions of peace to Napoleon and to declare war on him in case of refusal. She proceeded to offer the conditions above mentioned with the exception of that which refers to the Confederation of the Rhine. A congress met at Prague in the course of July, but Napoleon did not allow its deliberations to make serious progress. He paid no attention to an ultimatum presented on August 8th. On midnight of August 10–11 the armistice was declared to be at an end, and the doom of Napoleon was sealed. It was a strange decision on his part, but perhaps he judged rightly that he had no choice but between ruin and absolute, impossible victory!

Europe now plunges again into a struggle as desperate and as destructive as that of 1812. More evidently even than in 1812 is Napoleon responsible for this ruin of all civilization. He cannot any longer speak even of the liberty of the seas, for he is forced himself to admit that the Continental system is dead, and yet refuses to surrender that ascendency for which the Continental system had all along been the pretext. Infatuated France, however, has by this time furnished more than 400,000 men to perish in a contest where there might be chances, but could be no probabilities, of victory. His headquarters are now at Dresden, and his armies are arranged along the whole course of the Elbe from Bohemia to its mouth. This position has been somewhat weakened by the adhesion of Austria to the Coalition, for Austria masses her troops on the north-west of Bohemia, threatening Dresden and Napoleon's communications from the left side of the Elbe. The force of the allies (approaching 500,000 men) consists of three great armies, of which the first, principally Austrian, and commanded by Prince Schwarzenberg, is stationed on the Eger in Bohemia; the sovereigns are here. The old Prusso-Russian army, which had made the convention of Poischwitz, is still in Silesia. It contains more Russians than Prussians, but a Prussian officer is now put at the head of it. This is Blücher, the dashing general of hussars, now an old man of seventy years; on his staff are some of the leading theorists and enthusiasts of the new Prussian army, such as Gneisenau. But the bulk of the Prussian force is stationed in the mark of Brandenburg. In this final muster of the armies of Europe we see that the moral forces have passed over from France to the allies. In the French camp there reigns weariness and desire for peace, among the Prussians and Russians heroic ardour and devotion. But the old mismanagement reappears on the side of the allies. In the Bohemian camp Schwarzenberg's authority was almost annulled by the presence of the sovereigns; in Silesia the heroic Prussian general is in command of an army mainly Russian. But in the mark perhaps the greatest blunder was made, for here the main Prussian force was put under the orders of the crown prince of Sweden, the Frenchman Bernadotte, wholly alien to the German cause, and bent upon propitiating French public opinion with a view to the succession of Napoleon. Bernadotte is not the only member of the old republican opposition who is seen in the allied camp now that Napoleon's fall begins to be thought of as possible. Moreau, the man who helped in 1799 to found the consulate, desiring probably to see France ruled by a series of Washingtons each holding office for a short term, appears in the Austrian camp. If Napoleon was to be dethroned, who had a better right to succeed him?

The campaign opens with a blow aimed at Berlin, where perhaps Napoleon wished to extinguish the popular insurrection at its source. Oudinot marches on it from Baruth, and is supported by a force from Magdeburg; Davoust sends another corps from Hamburg. Bernadotte proposes to retire and sacrifice Berlin, but in spite of him Bülow fights on August 23d the battle of Grossbeeren, within a few miles of the capital. Here first the landwehr distinguished itself, and Berlin was saved. The attack from Magdeburg was defeated by Hirschfeld at Hagelberg on the 27th. Meanwhile Napoleon himself, at the head of 150,000 men, had marched against Blücher on the Katzbach. Blücher retired before him, and he was compelled to return to the defence of Dresden, but he left Macdonald with perhaps 50,000 or 60,000 men to hold Blücher in check. Almost immediately after his departure (August 26th) Macdonald was defeated by Blücher in the battle of the Katzbach. Thus the campaign began with two Prussian victories. But when the great army of Bohemia moved upon Dresden Napoleon showed his old superiority. On August 27th he inflicted on it a terrible defeat. In this battle Moreau, the hero of Hohenlinden, was mortally wounded by a cannon-ball. It seemed for a moment likely that this battle, followed up with Napoleon's overwhelming rapidity, would decide the campaign. He prepared to cut off his enemy's retreat into Bohemia. But the news of Grossbeeren and Katzbach arrived; Napoleon is also said to have been attacked by illness; he altered his plan in the moment of execution. The grand stroke of the campaign failed, and, instead of cutting off the retreat of the grand army, Vandamme was taken prisoner at Kulm with 10,000 men after a battle in which he had lost half that number (August 30th). It was evident that the times of Marengo and Austerlitz were over. Napoleon's ability and authority were as great as ever; he controlled larger armies; he opposed a Coalition which was as unwieldy as former Coalitions; and yet he had suffered four defeats in a single week and had won but one victory. Within another week he suffered another blow. A new advance was made on Berlin by Ney, who was defeated with great loss at Dennewitz by the Prussians under Bülow (September 6th).

Here then ends Napoleon's ascendency; henceforth he fights in self-defence or in despair. Yet the massacre was to continue with unabated fury for two months longer. He spent the greater part of September in restless marches from Dresden, now into Silesia, now into Bohemia, by which he wore out his strength without winning any substantial advantage. Towards the end of the month a new phase of the war begins. From the beginning the allies had given each other rendezvous in the plain of Leipsic. Hitherto Napoleon had held the line of the Elbe, and had presented a single mass to the three separate armies of the Coalition. Now that his collapse begins to be visible, begins the converging advance on Leipsic. The Silesian army crossed the Elbe at Wartenburg on October 3d, and on the next days the northern army also crossed at several points. At the same moment the Confederation of the Rhine began rapidly to dissolve. A troop of Cossacks under Czernicheff upset the kingdom of Westphalia (October 1st). Bavaria abandoned Napoleon, and concluded the treaty of Ried with Austria (October 8th). But for

Battle of Leipsic. form's sake a final massacre was still necessary. It took place on a satisfactory scale between October 14th and 19th, and ended in the decisive defeat of Napoleon and the capture of Leipsic. Perhaps nearly half a million of men were engaged in these final battles. It is reckoned that in the last three days the Prussians lost sixteen, the Russians twenty-one, and the Austrians fourteen thousand men—total, fifty-one thousand. Napoleon left twenty-three thousand behind him in the hospitals and fifteen thousand prisoners; his dead may have been fifteen thousand. He lost also three hundred pieces of artillery. The sufferings of the wounded almost exceed anything told of the retreat from Moscow. It is a misfortune that the victors allowed him to cross the Rhine in safety; had they pressed the pursuit vigorously, helped as they now were by the Bavarians, they might have brought his career to an end at this point. But for such a decisive measure perhaps even their political views were not yet ripe. However, as at the Berezina in 1812, so now, he had to clear his road by another battle. The Bavarians under Wrede met him at Hanau, eager to earn some merit with the victorious Coalition; but he broke his way through them and arrived at Frankfort. On November 1st and 2d he carried the remains of his army, some 70,000 men, across the Rhine at Mainz.

The work of eight years was undone; Napoleon was thrown back to the position he had occupied at the rupture of the peace of Amiens. The Russian disaster had cancelled Friedland; Leipsic had cancelled Austerlitz. But could Napoleon consent to humble himself? If he could not make concessions in the summer, still less could he do so now. Could he return and reign quietly at Paris, a defeated general, his reputation crushed by the two greatest disasters of history? But he might by abdicating have spared France, already mortally exhausted, the burden of another war. It is among the most unpardonable even of his crimes to have dragged his unhappy country through yet another period of massacre, though nothing that could even appear to be a national interest was at stake. In November advances were made to him by the allies, in which peace was proposed on the basis of the "natural frontiers." This would have secured to France the main fruits of the First Revolutionary War, that is, Belgium, the Left Bank, Savoy, and Nice. Such terms seem generous when we consider the prostration of France and the overwhelming superiority of the allies. But though the Prussian war-party loudly protested against them, and maintained the necessity of weakening France so as to render her harmless, Austria favoured them, being jealous alike of Prussia and of the spirit of liberty which the war was rousing in the German population. A little compliance on the part of Napoleon might at this moment have made the general desire for peace irresistible. But he showed no such disposition. He first evaded the proposal, and then, too late, accepted it with suspicious qualifications. After having been decimated, France must now be invaded and subjugated, for him.

Invasion of France by the allies. On December 1st the allies issued their manifesto from Frankfort, in which they declare themselves at war not with France but with Napoleon (an imitation of the Revolutionary principle "Peace with peoples, war with Governments"), and the invasion followed with almost Napoleonic rapidity. The three armies remain separate as they had been in Germany. The great army under Schwarzenberg passes through Switzerland, and makes its way to the plateau of Langres (the source of the Seine, Aube, and Marne), where it begins to arrive about the middle of January; Blücher's Silesian army crosses the middle Rhine to Nancy; the northern army, nominally under Bernadotte, passes through Holland. In the course of the march Switzerland and Holland were swept into the Coalition, the resources of which were now become overwhelming. It would be difficult to state for what object Napoleon now called on France to fight another campaign, particularly as the allies guaranteed to her a larger territory than she had possessed under the old monarchy. His officers indeed wondered what personal object he could have. They were astonished to hear him talk of another campaign in Germany to be undertaken next spring, of being soon on the Vistula again, &c. He was no doubt a prey to illusions, his fortune having accustomed him to expect results ten times greater than the probabilities justified, but his confidence was founded on (1) the great force which still remained to him shut up in German fortresses, (2) the mutual jealousy of the allies, (3) his own connexion with the emperor of Austria, (4) the patriotism which would be roused among the French, as in 1792, by the invasion. But his calculations were confounded by the rapidity of the invaders, who gave him no time to call out the nation. The Senate did indeed grant him 300,000 men, but to levy, drill, and arm them was impossible, and he had neglected to fortify Paris. In the armies which had returned from Germany there began desertion of all who were not French. The campaign opened at the end of January and was over at the end of March. The scene of it was the country between the Marne, Aube, and Seine, partly also the department of Aisne. At first, though successful at Brienne, Napoleon seemed unable to resist the superior numbers of the enemy. He was defeated at La Rothière. But the invaders were as yet irresolute; they divided their forces. This gave him an opportunity. He attacked Blücher, and, though with greatly inferior forces, won four battles in four days, at Champaubert (February 10th), at Montmirail (11th), at Château-Thierry (12th), at Vauchamps (13th). For the moment this brilliant success gave the campaign quite another character; the hopes and patriotic feelings of the French were roused. A congress had already been opened at Châtillon, and under the impression of these victories it would have been easy to conclude a peace, had not Napoleon's position made a reasonable peace inadmissible to him. He felt this, and fell back upon illusions and upon attempts to sever Austria from the Coalition. At the beginning of March the Coalition was strengthened by the treaty of Chaumont, in which each of the four powers bound themselves for twenty years to keep 150,000 men on foot. Directly afterwards Napoleon received a crushing blow from the fall of Soissons and the junction of Blücher with the northern army under Bülow, which had entered France by way of Holland and Belgium. Their united force amounted to more than 100,000 men. The battles of Craonne and Laon followed, in which Napoleon, without suffering actual defeat, saw his resources dwindle away. On March 18th the conferences at Châtillon came to an end, the plenipotentiaries of the allies declaring Napoleon to have no intention but that of gaining time. About the 24th the allies came to the resolution to march on Paris. They had before them only Marmont and Mortier, for Napoleon himself had resolved to manœuvre in their rear, and had marched to St Dizier. The marshals, after an engagement at Fère Champenoise, made good their retreat to Paris, where the enemy followed them on the 29th. Joseph Bonaparte withdrew Marie Louise and the king of Rome to Tours. On the 30th the allies attacked in three divisions,—the Silesian army on the side of Montmartre, Prince Eugene of Würtemberg and Barclay de Tolly by Pantin and Romainville, the crown prince of Würtemberg and Giulay by Vincennes and Charenton. In the afternoon, after an obstinate resistance, the marshals offered a capitulation, and engaged to evacuate the town before seven o'clock in the morning. Napoleon, advancing

by forced marches, was too late. The military struggle is over; the political struggle begins.

Since 1804 there had been no independent political life in France. During the Russian expedition, indeed, a certain General Malet had spread a false report of Napoleon's death in Russia, and had produced a forged decree of the Senate restoring the republic. His attempt had for the moment had so much success that Napoleon had painfully felt the precariousness of his dynasty, the purely provisional character of the monarchy he had founded. Again, when Napoleon had made his last appeal for help to the Corps Législatif, Lainé of Bordeaux had conjured the emperor, while he defended the country, to maintain the entire execution of the laws which guarantee to the French liberty, security, and property, and to the nation the free exercise of its political rights. Napoleon had replied with an outburst of indignation. But now at last it became necessary to take an independent resolution, for in the influential classes it began to be understood that Napoleon must fall, and in particular the generals asked themselves for what rational purpose troops were still levied and battles still fought. But not even the germs were visible of any authority that could replace that of Napoleon. Should he be succeeded by another general, or by a regency for his son, or by the Bourbons? The first course might have been possible had some Morean been at hand; even as it was, Bernadotte, who, like Napoleon, was a Jacobin developed into a prince, made pretensions which were favoured by the czar. Such a course would have been a revival of the consulate, but it would not have satisfied the republican party, while it would have been rejected by monarchists of every shade. In favour of the regency, as against the Bourbons, there was much to be said. It would not begin with a fantastic transformation-scene, and it would have a hold on the popular imagination. The decision fell out by a sort of accident. To a regency the natural road was by an abdication which would preserve the principle of inheritance. Such an abdication Napoleon gave. On April 4th he reviewed his troops at Fontainebleau, and announced his intention of attacking the allies in Paris. They received his words with enthusiasm; but just at this point the mainstay of his power failed him. The military aristocracy, the marshals, refused to follow him, and Napoleon perceived in a moment that the end was come. Though in arguing with them he had said that a regency of Marie Louise, whom he called "a child," was impossible, yet he now abdicated on condition that his son should succeed under the regency of the empress. Ney, Macdonald, and Caulaincourt set out for Paris to negotiate the establishment of the regency.

apoleon ab-di-cates.

Napoleon's power rested first on the support of the great military magnates, but secondly on the great civil dignitaries, lavishly enriched by him, whose organ was the Senate. While the marshals forced him to abdicate, his reign had been brought to an end in a wholly different way by the Senate. Talleyrand, vice-president of this body, who had for some time been intriguing in favour of the Bourbons, pronounced openly in favour of them before the sovereigns when they entered Paris. "The regency," he said, "was an intrigue; the Bourbons alone were a principle." He convoked the Senate on April 1st, and on April 2d it voted the deposition of Napoleon and his family. This decision was ratified the next day by the Corps Législatif.

Then occurred the abdication in favour of his family, which had the support of the army. The instrument was brought to Paris by not less than three famous marshals, Ney and Macdonald having been joined on their way from Fontainebleau by Marmont. The two solutions were thus brought together before the allied sovereigns, of whom Alexander was not favourably disposed to the Bourbons, and Francis was the father of Marie Louise. For a moment the balance trembled.

But Marmont had been brought in contact, during his defence of Paris, with Talleyrand, and had committed himself to him before he knew of the view of the marshals. After evacuating Paris he had been stationed on the Essonne. Here he had entered into an engagement to place his corps at the service of the new provisional Government which the Senate had constituted; the arrangement was that on April 5th the corps should quit its position and march into Normandy. But when the marshals passing through his camp from Fontainebleau told him of their commission, he had revealed his secret with expressions of penitence; he had countermanded his orders to the inferior officers, and had gone with the marshals to Paris. In his absence, however, General Souham, influenced by a fear that the plot had become known to Napoleon, gave orders to the troops to march on Versailles. This appearance of division in the army was fatal to Napoleon's family. It decided Alexander to declare for the Bourbons, and Caulaincourt was instructed to demand from Napoleon an abdication pure and simple. In return he was to retain the title of emperor, and to have the island of Elba in sovereignty, while Marie Louise was to have a principality in Italy.

By an irony of fortune the Government founded at Brumaire, in which everything had been sacrificed to military efficiency, was the only one of the three Governments of France since 1789 which actually succumbed before an invader. The total result of so many conquests was that France, which, when Napoleon's name was first heard of, was in substantial possession of Belgium, the left bank of the Rhine, Savoy, and Nice, had now lost the first two acquisitions; and we shall see what measures he took to deprive her of the other two. His fatal power of bewildering the popular mind was already at work again. This last campaign, the most unpatriotic he ever fought, had seemed to redeem his faults, and had given him the name of a heroic defender of his country. This view made way fast, as soon as he had the restored Bourbons for a foil.

In the meantime, however, all the hatred, long suppressed, of individuals and of parties broke loose upon him. For the moment he seems to have utterly lost heart. On the night of April 11th, after signing the unconditional abdication, he is said to have taken a dose of a poison which ever since the Russian campaign he had kept by him. But vomitings, we are told, came on and saved him. On the 20th, when he bade farewell to his soldiers, he had resolved to live in order "to narrate to posterity the great deeds we have done together." He soon found another object for life; but a year later, after another downfall far more complete and ignominious, he clings to life, and he clings to it afterwards in captivity. The soldiers idolized him still, and his parting scene at Fontainebleau, when he kissed the eagle, was pathetic; but when he reached the south of France he met with other demonstrations of feeling. At Avignon and Orgon the crowd attacked the carriages, and wanted to throw the tyrant into the Rhone. He was compelled to disguise himself. At the coast he was met by an English frigate which landed him on May 4th at Porto Ferraio, in Elba. It seems to have been arranged among the sovereigns that his wife and child were not to rejoin him, nor did he complain of this. Marie Louise set out on April 23d, and was at Schönbrunn again before the end of May. About the same time Josephine died at Malmaison, in the arms of her children Eugène and Hortense.

He retires to Elba.

It must have occurred to Napoleon very soon after his arrival in Elba that he was not yet driven to autobio-

Disquiet in France.

graphy. Never was a great state in a position so untenable and monstrous as France after he quitted the helm. In twenty years of thrilling events, in the emotions first of tragedy and then of epic poetry, the French had forgotten the Bourbon court, when suddenly the old Comte de Provence (under the name of Louis XVIII.) and the Comte d'Artois, Condé and the Duc d'Angoulême, and the Orpheline du Temple reappeared and took possession of the country before even a royalist party had formed itself in France. Politically, indeed, they brought liberty, for they created a parliament where all assemblies had been mute and servile for fourteen years; but they unsettled all domestic affairs, the position of public men, the prospects of the army, the title of estates, in a manner so sudden and intolerable, and that at a moment when the country had suffered conquest from without, that some new convulsion seemed manifestly imminent. Disgraced, bewildered, and alarmed at the same time, the French could think with regret even of the reign of Napoleon. The wholesale massacre of the last two years might have been expected to seem like a bad dream as soon as the spell was snapped, but it began to seem regrettable in comparison with the present humiliation. Another event happened which was like a new revolution. The prisoners and the troops shut up in German fortresses returned to France under the treaty, perhaps not less than 300,000 men. What could be more evident than that if all these soldiers could take the field again, and under Napoleon, France might yet escape the humiliation of a Government imposed by foreigners, and perhaps also recover her lost frontiers. The congress of Vienna entered upon business in September, and from this time a new chapter of politics opened. France ceased to be the general bugbear, and new alliances began to be formed in order to check the aggressive spirit of Russia. The European Coalition, once dissolved, might not be so easily reconstituted. Internal politics also had altered. A wild party of ultras had sprung up among the royalists; the church was beginning to give disquiet to the holders of national property; the army was enraged by seeing *émigrés* who had fought against France appointed in great numbers to the command of regiments.

It was not the first time that Napoleon had gone into a sort of exile. As he had disappeared in the East, and returned to make Brumaire, so he might come from Elba to rescue France. The situation was not less intolerable than in 1799. As then, so now, had he not returned, a revolution would, nevertheless, have taken place. Fouché was weaving a military plot, which would have carried to power perhaps the duke of Orleans, perhaps the king of Rome.

The Hundred Days.

He entered upon the last of his thousand adventures on February 20, 1815, when he set sail from Porto Ferraio with Generals Bertrand and Drouot and 1100 soldiers. On March 1st he reached the French coast between Cannes and Antibes. Twenty days after he entered the Tuileries in triumph.

He had judged the feeling of the army correctly, and also the effect which would be produced by his prodigious fame. These causes were more than enough to overthrow a Government so totally without root as that of the Bourbons. From the coast he took the way across the mountains of Provence by Sisteron and Gap to Grenoble. The soldiers sent from this town to stop him were disarmed when he uncovered his breast and asked, Which of them would fire on his emperor? He was then joined by the royalist La Bédoyère. Macdonald at Lyons stood firm, but was deserted by his soldiers. Ney, who commanded in the east, at first declared himself violently against his old chief, but the military feeling afterwards gained him, and he joined Napoleon at Auxerre. The king left the Tuileries on the 19th, retiring northward, and on the next day Napoleon entered Paris.

At Brumaire he had put down Jacobinism, and given the nation order and repose. Now he was summoned, in the name of liberty, to protect the acquisitions of the Revolution and to defend the national honour against the triumphant foreigner. The Hundred Days are the period of popular or democratic imperialism. Those who sided with him told him frankly that he must turn over a new leaf, and he professed himself ready to do so. It would be rash to say that this was impossible. He was but forty-five; his return from Elba was an astonishing proof that he still possessed that elasticity of spirit, that power of grasping the future, which he had often shown so remarkably. Here then, as at a second Brumaire, might begin a third Napoleonic period. The mad crusade against England and the world-empire which sprang out of it were now to be forgotten; he was to stand out as a hero of national independence and of modern ideas together, a representative of the free modern people against the Holy Alliance. This last and most surprising of his transformations was already most prosperously begun. But at this point fortune deserted him once for all. Napoleon Liberator remained a poetical idea, transforming his past life into legend, and endowing French politics with a new illusion; the attempt to realize it came to an end in a hundred days (March 13 to June 22).

The ultimate cause of this failure seems to have been a change in Napoleon himself. It had long been remarked that the emperor Napoleon was wholly different from the general Bonaparte of the Italian campaigns. Bonaparte had been lean, shy, laconic, all fire and spirit, the very type of republican virtue imagined by Rousseau; the emperor was fat and talkative, and had his fits, according to Marmont, of indolent ease. Once or twice there had been attacks of illness, by which he had been temporarily incapacitated; but this had been hushed up. On the whole he had never yet been wanting to himself. In the campaign of 1814 his activity had been prodigious, and the march to Paris in twenty days, with which he had opened 1815, had been a great display of vigour. But he could not maintain himself at this level. A physical decay had begun in him, affecting through his body, not indeed his mind, but his will and his power of application. "I do not know him again," said Carnot. "He talks instead of acting, he the man of rapid decisions; he asks opinions, he the imperious dictator, who seemed insulted by advice; his mind wanders, though he used to have the power of attending to everything when and as he would; he is sleepy, and he used to be able to sleep and wake at pleasure." This last symptom was the most striking; in some of the most critical and terrible moments of the Waterloo campaign he seems to have been scarcely able to keep himself awake.

The constitutional history of the Hundred Days may be despatched summarily, since it led to nothing. On March 13 an imperial decree was issued from Lyons dissolving the two chambers established by the Bourbons, and convoking an extraordinary assembly in Field of May for the purpose "of correcting and modifying our constitutions and of assisting at the coronation of the empress, our dear and well-beloved spouse, and of our dear and well-beloved son." But the prospect soon changed, and, as it was necessary that the empire, like the monarchy, should have its charter, it seemed impossible to wait till May. Napoleon had recourse to Benjamin Constant, that is, he marked his change of policy by sending for the leader of the opposition. The "Acte Additionnel aux Constitutions de l'Empire," dated April 22, was drawn by Constant, examined by a committee, and then adopted by the council of state. The most remarkable feature of it is the preamble,

in which he explains his change of attitude by saying that "formerly he had endeavoured to organize a grand federal system in Europe, which he had regarded as agreeable to the spirit of the age and favourable to the progress of civilization," that "for this purpose he had adjourned the introduction of free institutions," but that "henceforward he had no other object but to increase the prosperity of France by strengthening public liberty."

This neat misrepresentation deserves notice as having imposed on many people. For the rest it is to be observed that this act creates an hereditary peerage. The Field of May was held, but not till June 1. Napoleon appeared in a grand costume and distributed flags, but the "well-beloved spouse and son" were not there; Europe had declared against him. On the 12th he set out for the campaign.

The great powers had issued, immediately on hearing of Napoleon's disembarkation (March 13th), a declaration putting him outside all civil and social relations, and consigning him to public vengeance as "an enemy and disturber of the peace of the world." On March 25th they reconstituted the Coalition. Was this a disappointment to Napoleon? A war of liberation was perhaps necessary to him. To be freely accepted by the French people, and then to be rejected by Europe, gave him precisely the opportunity he sought of standing forth as the heroic champion of national independence. He had now all the soldiers who at the time of his first fall had been locked up in fortresses or foreign prisons. His position was therefore such as it had been in 1813, not in 1814, and he proposed to defend not a vast empire but simply France, so that he had on his side patriotism and liberalism. All this, and his own genius! Would not so much suffice? Probably he remembered Brumaire, how low the fortune of France at that time had been, and how suddenly Marengo had restored all. For the moment, however, the inequality of numbers was great. In June the allies had in the field more than 700,000, Napoleon little more than 200,000, men. There were already English troops in Belgium, where they were engaged in establishing the new kingdom of the Netherlands, and there were Prussian troops in the Rhenish province which had just been given to Prussia. It was a question for Napoleon whether he should assume a defensive attitude and allow the allies to invade France—this in itself would have suited his new policy best—or carry the war into Belgium, a country long united with France, and attack the English and Prussians. He shrank from inflicting a new invasion upon France, especially on account of the strength of the royalist party in many regions, and thus it was that the scene of the campaign was laid in Belgium. The English had their headquarters at Brussels, the Prussians at Liége. He formed the plan of dividing them and beating them in turn, as he had served the Austrians and Sardinians at the very beginning of his career. Many circumstances, however, were different. Wellington and Blücher with Gneisenau were superior to Colli and Beaulieu; the Napoleon of 1815 was vastly inferior to the Bonaparte of 1796.

Of all the Napoleonic campaigns this was by far the most rapid and decisive. Even the Marengo campaign had lasted a month, but this was decided in three days. Leaving Paris on the 12th, Napoleon was in Paris again on the 21st, his own fate and that of his empire and that of France decided. Everything concurred to make this short struggle the most interesting military occurrence of modern history: its desperate intensity, its complete decisiveness, the presence for the first and last time of the English army in the front of the European contest, the presence of the three most renowned commanders, Napoleon, Wellington, and Blücher. Accordingly it has been debated with infinite curiosity, and misrepresented on all sides with infinite partiality. Napoleon's army amounted to 122,401 men; it contained a large number of veterans, besides many who had seen the campaigns of 1813–14, and was perhaps the finest army he had ever commanded. That of Wellington was composed of Englishmen, Hanoverians, Brunswickers, Nassauers, Germans, and Netherlanders; the total is stated at 105,950. But in the Netherlanders of the newly-established kingdom no confidence could be placed, and yet these amounted to nearly 30,000; the English too (about 35,000) were in great part raw recruits (the Peninsular veterans being mainly absent in America); altogether Wellington pronounced it "the worst army ever brought together." The army of Blücher numbered 116,897 disciplined troops, animated by an intensely warlike spirit. Napoleon's opening was prosperous. He maintained so much secrecy and used so much rapidity that he succeeded in throwing himself between the two armies. On the 15th he advanced and occupied Charleroi. On the 16th he engaged the Prussians at Ligny and the English at Quatrebras, desiring to block the cross-road between Quatrebras and Sombreffe, and so to sever the two armies. Napoleon personally commanded against the Prussians, and here he gained his last victory. The battle was very bloody; about 12,000 Prussians fell, and Blücher himself was wounded. At Quatrebras Ney met Wellington and was forced to retreat. But the defeat of Blücher made it necessary for Wellington to retire on Brussels in order to effect a junction with the Prussians. The 17th was spent in this retrograde movement, and on the 18th Wellington accepted battle on the heights of St Jean, from which the French name it, while the English give it the name of Waterloo, a village four miles nearer to Brussels, where Wellington wrote his despatch. He accepted battle in full reliance upon the help of the Prussians, who are not therefore to be considered as having saved him from defeat.

Battle · Waterl.

Military writers point out several errors, some of them considerable, committed by Wellington, but their criticism of Napoleon, which begins by sweeping away a mass of falsehood devised by himself and his admirers in order to throw the blame upon others, is so crushing that it seems to show us Napoleon after his brilliant commencement acting as an indolent and inefficient general. He first, through mere want of energy, allows the Prussians to escape him after Ligny, and then sends Marshal Grouchy with 33,000 men in the wrong direction in pursuit of them. Owing to this mismanagement Grouchy is at Wavre on the day of the battle of Waterloo, fighting a useless battle against the Prussian corps of Thielemann, while Blücher is enabled to keep his engagement to Wellington. Everywhere during these days Napoleon appears negligent, inactive, inaccessible, and rather a Darius than an Alexander, so that it has been plausibly maintained that he was physically incapacitated by illness. The battle itself was one of the most remarkable and terrible ever fought, but it was perhaps on both sides rather a soldiers' than a generals' battle. It consisted of five distinct attacks on the English position:—(1) an attack on the English right by the division Reille, (2) an attack on the left by the division D'Erlon (here Picton was killed), (3) a grand cavalry attack, where the splendid French cavalry "foamed itself away" upon the English squares, (4) a successful attack by Ney on La Haye Sainte (which Wellington is thought to have too much neglected; it was after this that the French prospect seemed brightest), (5) the charge of the guard. In the middle of the third act of this drama the Prussians began to take part in the action: The battle seems to have begun about 11.30, and about 8 o'clock in the evening the cry "Sauve qui peut"

rose from the guard. A general advance of the English decided the victory, and then the pursuit was very thoroughly accomplished by the Prussians under Gneisenau. Napoleon at first took refuge in a square. At Genappe he left this, and arrived at Charleroi about daybreak with an escort of about twenty horsemen.

He lost probably more than 30,000 out of 72,000 men, but the grand army was utterly dissolved. The whole loss of the allies was somewhat more than 22,000. Had Napoleon been victorious, he would but have opened the war prosperously, for half a million soldiers, in addition to those of Wellington and Blücher, were on the march for France; being completely defeated, he had no resource, but was ruined at once. France was conquered, as she had been conquered the year before; but her second fall appears far more humiliating and dismal than her first, when we consider how enthusiastically she had rallied to Napoleon and how instantaneously Napoleon and she had been struck down together. It was a moment of unrelieved despair for the public men who gathered round him on his return to Paris, and among these were several whose fame was of earlier date than his own. La Fayette, the man of 1789; Carnot, organizer of victory to the Convention; Lucien, who had decided the revolution of Brumaire,—all these met in that comfortless deliberation. Carnot was for a dictatorship of public safety, that is, for renewing his great days of 1793; Lucien too liked the Roman sound of the word dictator. "Dare!" he said to his brother, but the spring of that terrible will was broken at last. "I have dared too much already," said Napoleon. Meanwhile, in the Chamber of Representatives the word was not dictatorship but liberty. Here La Fayette caused the assembly to vote itself permanent, and to declare guilty of high treason whoever should attempt to dissolve it. He hinted that, if the word abdication were not soon pronounced on the other side, he would himself pronounce the word "dechéance." The second abdication took place on June 22d. "I offer myself a sacrifice to the hatred of the enemies of France. My public life is finished, and I proclaim my son emperor of the French." On the 25th he retired to Malmaison, where Josephine had died the year before. He had by no means even yet ceased to hope. When his son was passed over by the Chamber of Representatives, who named an executive commission of five, he protested that he had not intended to make way for a new Directory; and, as Carnot and Caulaincourt were on this commission, the circumstances of Brumaire seem to have flashed into his memory. He saw again two Directors supporting him, and the other three (Fouché, Grenier, and Quinette—a traitor and two babies, as he expressed it) might remind him of Barras, Moulin, and Gohier. On the 27th he went so far as to offer his services once more as general, "regarding myself still as the first soldier of the nation." He was met by a refusal, and left Malmaison on the 29th for Rochefort.

The second abdication.

France was by this time entering upon another Reign of Terror. Massacre had begun at Marseilles as early as the 25th. What should Napoleon do? He had been before the enemy of every nation, and now he was the worst enemy, if not of France, yet of the triumphant faction in France. He lingered some days at Rochefort, where he had arrived on July 3d, and then, finding it impossible to escape the vigilance of the English cruisers, went on the 15th on board the "Bellerophon" and surrendered himself to Captain Maitland. It was explained to him that no conditions could be accepted, but that he would be "conveyed to England to be received in such manner as the prince regent should deem expedient." He had written at Rochefort the following characteristic letter to the prince regent:—"Royal Highness,—A prey to the factions which divide my country and to the enmity of the greatest powers of Europe, I have terminated my public career, and I come, like Themistocles, to seat myself at the hearth of the British people. I place myself under the protection of its laws, which I claim from your royal highness as the most powerful, the most constant, and the most generous of my enemies."

Surrender to England

It was perhaps the only course open to him. In France his life could scarcely have been spared, and Blücher talked of executing him on the spot where the Duc d'Enghien had fallen. He therefore could do nothing but what he did. His reference to Themistocles shows that he was conscious of being the worst enemy that England had ever had. Perhaps he remembered that at the rupture of the treaty of Amiens he had studied to envenom the contest by detaining the English residents in France. Still he might reflect, on the other hand, that England was the only country which had not been trampled down and covered with massacre by his soldiers. It would have been inexcusable if the English Government had given way to vindictive feelings, especially as they could well afford to be magnanimous, having just won the greatest of all victories. But it was necessary to deprive him of the power of exciting new wars, and the experiment of Elba had shown that this involved depriving him of his liberty. The frenzy which had cost the lives of millions must be checked. This was the principle laid down in the declaration of March 15th, by which he had been excommunicated as a public enemy. It was therefore necessary to impose some restraint upon him. He must be separated from his party and from all the revolutionary party in Europe. So long as he remained in Europe this would involve positive imprisonment. The only arrangement therefore which would allow him tolerable personal comfort and enjoyment of life was to send him out of Europe. From these considerations grew the decision of the Government to send him to St Helena. An Act of Parliament was passed "for the better detaining in custody Napoleon Bonaparte," and another Act for subjecting St Helena to a special system of government.

He was kept on board the "Bellerophon" till August 4th, when he was transferred to the "Northumberland." On October 15th he arrived at St Helena, accompanied by Counts Montholon, Las Cases, and Bertrand, with their families, General Gourgaud, and a number of servants. In April 1816 arrived Sir Hudson Lowe, an officer who had been knighted for bringing the news of the capture of Paris in 1814, as governor.

Exile in St Helena

The rest of his life, which continued till May 5, 1821, was occupied partly in quarrels with this governor, which have now lost their interest, partly in the task he had undertaken at the time of his first abdication, that of relating his past life. He did not himself write this narrative, nor does it appear that he even dictated it word for word. It is a report made partly by General Gourgaud, partly by Count Montholon, of Napoleon's impassioned recitals; but they assure us that this report, as published, has been read and corrected throughout by him. It gives a tolerably complete account of the period between the siege of Toulon and the battle of Marengo. On the later periods there is little except a memoir on the campaign of 1815, to which the editors of the *Correspondence* have been able to add another on Elba and the Hundred Days

Autobiography

These memoirs have often been compared to the *Commentaries* of Cæsar, and their value would indeed be priceless if they related to a period imperfectly known. But an age which has abundance of information, and takes history very seriously, is struck particularly by the elaborate falsifications which they contain. A vast number of misstatements, many of them evidently intentional, have

been brought home to him, and in several cases he has tried to foist into history apocryphal documents.

Here, as throughout his life, he shows quite a peculiar talent for misrepresentation. He knows that nine readers out of ten take a lucid statement for a true one, and his statements are always lucid, precise, and direct. And thus it has been, and is, particularly difficult to eradicate the Napoleonic legend, which has grown up in the very midst of the 19th century, and would perhaps never have been seriously shaken but for the failure of the Second Empire. Its growth was helped by the accident that at the moment of quitting the scene he seemed to be fighting for a good cause. Look at Napoleon's career between 1803 and 1814, when it was shaped most freely by his own will; here everything is anti-popular, illiberal, and immoral, as well as ruinous beyond all precedent. In particular he stands out as the great enemy and oppressor of nationalities, so that the nationality movement, when it begins in Spain and Tyrol and spreads through North Germany, is a reaction against his tyranny. But in 1815 he succeeded in posing as a champion and martyr of the nationality principle against the Holy Alliance. The curtain fell upon this pose. It brought back the memory of that Bonaparte who at the end of the 18th century had seemed the antique republican hero dreamed of by Rousseau, and men forgot once more how completely he had disappointed their expectations. By looking only at the beginning and end of his career, and by disregarding all the middle of it, an imaginary Napoleon has been obtained who is a republican, not a despot, a lover of liberty, not an authoritarian, a champion of the Revolution, not the destroyer of the Revolution, a hero of independence, not a conqueror, a friend of the people, not a contemner of the people, a man of heart and virtue, not a ruthless militarist, cynic, and Machiavellian. This illusion led to the restoration of the Napoleonic dynasty in 1851.

ıth. He died of an ulcer in the stomach on May 5, 1821. In his will he declared himself a Catholic, wished his ashes to repose "on the banks of the Seine in the midst of the French people whom he had loved so well," spoke tenderly of Marie Louise and his son, and of all his relatives except Louis, whom he "pardoned" for the libel he published in 1820, disavowed the *Manuscrit de Sainte-Hélène*, a mystification which had recently had much success, defended the execution of D'Enghien, imputed the two conquests of France to Marmont, Augereau, Talleyrand, and La Fayette, whom he "forgave," and devoted the English oligarchy, to whom he ascribed his premature death, to the vengeance of the English people. In a codicil he added a truly Corsican touch, bequeathing 10,000 francs to the subaltern officer Cantillon, "who has undergone a trial upon the charge of having endeavoured to assassinate Lord Wellington, of which he was pronounced innocent. Cantillon had as much right to assassinate that oligarchist as the latter had to send me to perish upon the rock of St Helena."

He was buried at Longwood in St Helena; but in the reign of Louis Philippe his remains were removed by permission of the English Government to the Invalides at Paris, where a stately dome was erected over the sarcophagus that contains them.

Posterity has not yet ceased to be perplexed by Napoleon's career. He inflames national partialities more than any other personage, and his activity, by embracing many countries, transcends the field of view of the historians of each nation. Till a recent time his life was written chiefly from French memoirs,—when by French writers, with great ignorance of all affairs not French, when by English writers, with imperfect knowledge of all affairs not French or English, and by all writers alike, especially French writers, with extreme prejudice. Then came M. Thiers (1845), professing to write from official papers; but his untrustworthiness in particular matters has long been demonstrated, and some recent investigators (see, for instance, De Martel, *Les Historiens Fantaisistes*) profess to convict him of the most outrageous contempt for truth. The story is now being slowly transferred from the basis of memoirs to that of official papers and correspondence. The *Correspondence* of Napoleon himself in thirty-two volumes (which began to appear in 1858) is necessarily the corner-stone, though it has been edited in the most unsatisfactory way, many letters having been withheld and others mutilated, even if some have not been garbled. On this foundation M. Lanfrey based his history, which extends unfortunately only as far as 1811. It is the first essay towards a serious estimate of the career; what the writer chiefly wants is a first-hand knowledge of the affairs of foreign nations. It still remains to fuse together these materials with those equally rich that have been lately furnished by German research and by the opening of the different national archives. On German affairs the principal works are those of Ranke, Pertz, Oncken, and Treitschke. For the substance of them the English reader may refer to Professor Seeley's *Life and Times of Stein*. A good account (founded on original documents) of the Russian campaign by Bogdanovitch may be read in German. Colonel Jung in two works, *Bonaparte et son Temps* and *Lucien Bonaparte et ses Mémoires*, shows himself a true historical critic. The former work renders earlier books on the first period of Bonaparte (Coston, Libri, &c.) superfluous. Of military works, Rüstow on the Italian campaigns, Charras on the campaign of 1815, and Charras's fragment on the campaign of 1813, with Mr Dorsey Gardner's volume on the campaign of 1815, may be recommended. Recent years have also brought valuable new memoirs, those of Marmont, of Miot de Melito, of Hardenberg (included in Ranke's *Life*), of Mme. de Rémusat, of Metternich. Mme. de Rémusat with the Duchesse d'Abrantès gives the best picture of his private life. This whole class of books should be used with caution. Marmont often excites distrust; still more the earlier memoir-writer Bourrienne. The reader must also be on his guard against apocryphal works, such as *Mémoires tirés des papiers d'un homme d'état*, long attributed quite without ground to Hardenberg, and the *Manuscrit venu de Ste-Hélène*. Literature.

(J. R. S.)

NAPOLEON II. is the name given by Bonapartists to François Charles Joseph, duke of Reichstadt, the son of Napoleon I. and Marie Louise, who was born at Paris 20th March 1811, and died of laryngeal phthisis at Schönbrunn, near Vienna, 22d July 1832. His empty imperial title is derived from his father's two abdications in his favour in 1814 and 1815. He was created duke of Reichstadt in 1818 by his grandfather Francis I. of Austria, at whose court he resided after his father's fall.

NAPOLEON III. (1808–1873). Louis Napoleon, emperor of the French, was the younger son of Louis, king of Holland (brother of Napoleon I.), and of Hortense, daughter of the empress Josephine by her first husband Beauharnais. He was thus both nephew and step-grandson of Napoleon I. His father and mother were on the worst terms, and rarely lived together. Louis was born at Paris on April 20, 1808, at the house belonging to his mother in the street that is now Rue Lafitte. He was brought up at Paris, and was occasionally taken to the Tuileries and noticed by the emperor, who gave him the cordon of the Legion of Honour. But it is impossible that the child could have remembered much of Napoleon I., who, from the beginning of the Russian campaign in 1812, was constantly away from Paris. When, in 1814, the allies entered the French capital, generosity towards the conquered was the order of the day. Queen Hortense was courteously treated and visited by the czar Alexander, to whom her boy is said to have given a ring. The family continued to reside in France during the first restoration of the Bourbons, and were there when Napoleon returned from Elba. A story that when Napoleon was on the point of setting out for Waterloo the young Louis interrupted him in a conference with Marshal Soult, and begged him not to go to the war, is probably mythical. The

second restoration of the Bourbons was not effected in so gentle a spirit as the first. The family of the Bonapartes was banished from France. Hortense—who, like the rest of her kindred, had enriched herself out of public property —retired to Switzerland, and purchased the chateau of Arenenberg, overlooking the Lake of Constance. The next fifteen years were passed by the young Louis partly at Arenenberg and partly at Augsburg, which his mother chose as the place of his education. He grew up a gentle, studious, brooding youth, and the influence of his Augsburg schooling remained both in his habits of thought and in his German-like pronunciation, which was noticeable long afterwards. Until 1830 he attracted little attention from those around him, and none at all from the world, for he was as yet only one among several cadets of the Napoleonic house, Napoleon's own son, the duke of Reichstadt, being still alive. He seems, however, to have had dreams of a great future at an early age; and the instinct that some knowledge of military affairs would be useful to him led him to serve as an artillery volunteer in the Swiss camp of Thun under Colonel Dufour. The revolution of 1830, which dethroned the Bourbons and awoke insurrectionary movements in so many countries, first launched Louis Napoleon upon his eventful career. Along with his elder brother he joined the Italian bands who were in revolt against the rule of the pope in Romagna. This revolt was put down by Austrian soldiers. The elder of the two brothers fell ill and died at Forli; Hortense, setting out to rescue her sons from their danger, found one dead and the other ill with fever, and on the point of falling into the hands of the Austrians at Ancona. After nursing Louis through his illness she succeeded in carrying him away in disguise, and the mother and son, after a most perilous journey, reached France, which they had not seen for sixteen years. They arrived in Paris in April 1831; but the law banishing the Bonapartes was still in force, and the Government of Louis Philippe did not allow them to remain there more than twelve days. They were sent on, like other exiles, to England, and stayed for some weeks in London, from which they returned to Arenenberg. Louis, now twenty-three years old, was beginning to form the political theories which the memory of the first empire and the actual state of affairs in France under Louis Philippe naturally suggested to a thoughtful and ambitious mind. A pamphlet called *Political Reveries*, containing the draft of a constitution for France, and an *Essay on Switzerland, Political and Military*, were written by him in 1832-33. The first of these contains in a crude and superficial form the ideas elaborated by the author in his later works; the second gained for him the complimentary rank of captain of artillery from the authorities of Bern. Louis remained quiet for some years in Switzerland, but the death of the duke of Reichstadt in 1832 had made him presumptive head of the house of Bonaparte,—his uncle Joseph, the actual head, having no sons; and, in company with some adventurous friends, he formed the design of overthrowing Louis Philippe's Government by presenting himself to the army. On the 28th October 1836 he came to Strasburg, and, after passing the next day in consultations with Colonel Vaudrey and a few officers who were in the plot, appeared at the quarters of the 4th artillery regiment, which Vaudrey commanded. This regiment welcomed him, and Louis then went on to the infantry barracks, where, however, the enterprise ended disastrously. He was arrested and imprisoned, and, after a short interval, sent to America by Louis Philippe without trial. He had not long been in the United States when he received a letter from his mother stating that she was about to undergo a dangerous operation. He returned to Switzerland in time to see her before her death (October 5, 1837), denying, probably with truth, that he had made any promise to Louis Philippe to remain absent from Europe. A pamphlet on the Strasburg affair, which was now published at his instigation by one of his companions, Lieutenant Laity, led the French ministry to demand his expulsion from Switzerland. The Swiss Government declining to expel him, and, difficulties with France becoming imminent, Louis voluntarily withdrew from the country and went to England. He lived there for the next two years, renting a house in Carlton Terrace, leading the life of a man of fashion, and associating with persons of prominence in society and on the turf. Among the gaieties of the time in which he took a part was Lord Eglinton's famous tournament. His real interests, however, were of a more serious character, and in the autumn of 1839 he published the treatise *Des Idées Napoléoniennes*, a vigorous but sophistical account of Napoleon's work as an administrator and organizer, and of his foreign policy. He idealized the emperor, contrasting his internal government with that of his successors in a series of questions addressed to the existing rulers of France, and he exhibited his wars of conquest as struggles forced upon him by the English and other Governments in consequence of his efforts to spread civilization, and to unite the peoples of Europe in a federal tie. This work was intended by its author to prepare the way for a new attempt against Louis Philippe; and in August 1840, while the body of Napoleon was being brought back from St Helena, he made his second descent upon France. Above fifty persons assisted him on this occasion, the best-known being Count Montholon, a companion of Napoleon I. in his exile. A ship was chartered, and the conspirators landed at Boulogne, carrying with them a tame eagle. The enterprise had not even the gleam of success which attended the expedition to Strasburg. No one joined them, and within an hour or two those of the party who were not shot or drowned in attempting to escape were lodged in prison. Louis was now brought to trial before the Chamber of Peers, where he was defended by Berryer. He was condemned to perpetual imprisonment, and the castle of Ham, on the Somme, was chosen as the place of his captivity. For the next six years Louis remained in confinement. He had the qualities which enable a man to bear imprisonment well,—patience, calmness, a low vitality and sluggish temperament, and the power of absorbing himself in work. The fortitude with which, during these six dreary years, he pursued the occupations which he had marked out for himself, and retained, with intervals of depression, the belief in his own future, had certainly something of nobility in it. "Happiness," he wrote, "lies much more in the imagination than in the real world; and as I carry my imaginary world with me, composed of memories and hopes, I feel as strong in solitude as in the crowd." In later life he described the prison of Ham as the university where he had taken his honours; and it was no doubt within this prison that he made himself, so far as literary study and discipline ever made him, a statesman. He published at intervals during his confinement, besides numerous occasional papers, an essay on the sugar question, in which he advocated a policy of protection; a treatise on the *Extinction of Pauperism*, in which he proposed the colonization of waste lands, and the establishment of communities organized on a somewhat socialistic basis; a scheme for cutting through the isthmus of Panama; and historical fragments on the English Revolution of 1688. He was working also at a *History of Artillery*, which was never finished. At the end of six years, after asking in vain for permission to visit his father, who was dying, Louis effected his escape, disguising himself with the aid of his faithful friend and fellow-prisoner,

Dr Conneau, as a workman, and walking out of the gates of the castle with a plank over his shoulder (May 25, 1846). He went again to London, and it is characteristic of the life of exile and imprisonment which he had hitherto passed that he heard for the first time a French tragedy performed when Rachel played in London in July 1846. He was now again in the fashionable world, and he appears to have been compelled to raise very large sums of money from money-lenders. The house in which he lived was No. 10 King Street, St James's. In February 1848 Louis Philippe lost his throne. Louis Napoleon at once set off for Paris, offering his services to the provisional Government. He was, however, requested to withdraw from France, and did so. In April 1848, during the Chartist disturbances, he was serving in London as a special constable. But his name was kept before the public in France; he was put up for election to the assembly, and was elected at Paris and in three departments. As a Bonapartist movement was now evidently beginning, the executive commission demanded authority to arrest Prince Louis as an avowed pretender. This, however, was refused by the assembly, and it was voted that he should take his seat. Louis, however, had the astuteness to remain in the background until the workmen's insurrection of June was over, declaring himself unwilling to be the cause of any disturbance. The insurrection was put down by Cavaignac; reaction set in, and Louis now appeared upon the scene as the candidate of order and the representative of authority. His first appearance in the assembly was on September 26, 1848; and in December he was elected president of the republic by above 5,000,000 votes, Cavaignac, who was second on the list, receiving a million and a half, and Lamartine a few thousands. On assuming office he swore in the presence of God to remain faithful to the republic, and to fulfil the duties imposed on him by the constitution. From this time the political history of Louis Napoleon is the history of France (see article FRANCE). The principal foreign affair of his presidency was the expedition to Rome, in which, for the sake of anticipating the action of Austria, French troops put down the Roman republic by force, and restored the pope to his sovereignty. Abroad this gained for Louis Napoleon the bitter hostility of Italian patriots, who remembered him as a companion in insurrection against the pope in 1831; and it was one of the many inconsistencies of his position that he was at once a friend of Italian freedom in his heart and yet, as the "man of order" and the "saviour of society" in France, dependent to a great extent upon the support of the priesthood. On the 2d of December 1851 he executed the *coup d'état*, which made an end of constitutional government. Approved at first by an enormous majority of the French people, and even by English public men of the type of Palmerston, this act is now almost universally recognized as a disastrous crime. The sham constitution which was promulgated by the president immediately afterwards lasted less than twelve months. In the following November a plebiscite was taken upon the question whether the imperial dignity should be re-established in the person of Louis Napoleon, and an affirmative answer was given by nearly 8,000,000 voters, against a dissentient minority of 250,000. The empire was inaugurated on the anniversary of the *coup d'état*, and for eighteen years Louis Napoleon was sovereign of France. The first ten years of his reign were successful, and in some respects brilliant. His marriage with Eugenie de Montijo, countess of Téba (January 30, 1853), placed beside him a figure which long charmed Paris and its visitors. Adhering to the alliance with England which, since 1830, had served France well against the three eastern courts, Napoleon III. entered into war against Russia. He had always represented the restoration of Poland to be one of the tasks left by his uncle to France; and, had his army encountered fewer difficulties in the Crimea, or had the German powers shown any inclination to take part in the struggle against Russia, he would probably have made some serious attempt to restore at least the duchy of Warsaw. But he was no soldier himself; the war proved a serious and embarrassing matter, and in the end Napoleon was far more anxious to make peace than his English ally. The second nationality which associated itself with Napoleonic history, and which had been crushed by the treaties of 1815, was the Italian. Napoleon III. had warning that the cause of Italy could not be safely abandoned. In January 1858 Orsini attempted to take his life. Whether or not the act of Orsini and the letters which he wrote from prison had the effect of quickening the emperor's determination to do something for Italy may be disputed; but the time had now come, and in the interviews which took place between Napoleon and Cavour at Plombières in the autumn of 1858 the alliance between France and Sardinia against Austria was arranged. In the spring of 1859 French armies entered northern Italy, and the emperor himself took command. On the 4th of June he witnessed the battle of Magenta, and on the next morning entered Milan in company with Victor Emmanuel. During the battle of Solferino on June 24th, he gave directions from the tower of the church of Castiglione. He met the emperor of Austria at Villafranca on July 11th, and there agreed to those preliminaries of peace which so deeply disappointed the hopes that had been excited by his own words,—"Italy free from the Alps to the Adriatic." Venice was left to Austria; Lombardy west of the Mincio alone was liberated; and the subsequent union of the peninsula under the house of Savoy was no work of Napoleon III., whose own plan was to form an Italian federation under the presidency of the pope, and in virtual dependence upon France. Nevertheless the expulsion of Austria from Lombardy was in itself so great a blow that the later effects, though not foreseen by Napoleon, naturally resulted from it; and he has a better title to the gratitude of the Italians than they have generally acknowledged. The feelings with which Napoleon was regarded in Italy before and after the meeting of Villafranca are well exhibited in Mrs Browning's two poems, *Napoleon in Italy* and *An August Voice*. The annexation of Nice and Savoy to France excited great uneasiness in the British Government, but the treaty of commerce between France and England, which was signed in January 1860, gave the emperor a popularity in England which he retained even after his fall. With the termination of the Italian war and the inauguration of a policy of free trade the rule of Napoleon III. had reached its best. His ill-judged interference in the affairs of Mexico ended disastrously; the part played by France in reference to the Danish War of 1864 was weak and inconsequent; and when the great struggle between Prussia and Austria was impending Napoleon appears to have been duped by Count Bismarck, and to have expected to gain Rhenish territory without taking up arms. Meanwhile the splendour of the court, the continuous improvements in Paris, the rapid growth of wealth throughout France, the subservience of officials, deputies, and journalists, had veiled the decline of administrative energy and the progress of corruption and mismanagement. At length, after the establishment of a great North-German power in 1866, the prestige of the emperor unmistakably sank. He had to loosen the reins of government at home; and yet the grant of any degree of liberty appeared to jeopardize his own existence. Failing in health, in confidence, in reputation, he was hurried into the war of 1870 by the clerical party at court, and by advisers who saw no help

for his dynasty but in a successful war. He was present with his only child[1] at the bombardment of Saarbrücken on August 2d, and then retired into Metz, which he left on the 15th, the day between the battles of Courcelles and Mars-la-Tour. The empress insisted on the relieving movement which was then undertaken by Macmahon, and the emperor, going with the army, was made prisoner with 90,000 men at Sedan on September 2d. He was sent to the castle of Wilhelmshöhe, near Cassel, from which he subsequently retired to England. He lived with the empress at Chislehurst, and died there on January 9, 1873.

Napoleon III. was a thinker and man of letters rather than a statesman. Presuming on the accident of birth to seize absolute power and to direct the affairs of a great nation, he proved himself totally incapable as an administrator, and allowed office, political and military, to fall into the most unfit hands. Far superior himself, as a man of ideas, to his conqueror the king of Prussia, he never chose and never possessed a minister or a general who could be compared with those selected by his rival. In private life he was kindly and amiable, and the worst acts of his reign were rather those of the adventurers who surrounded him than his own. (C. A. F.)

NAPOLEON, a round game of cards. Any number may play; about four or five makes the best game. When six play the dealer deals himself no hand, but pays or receives the same as the other players. A pack of fifty-two cards is required. The players cut for deal; the lowest deals. The cards rank as at whist; and the deal goes afterwards in rotation to the left, as at whist. The cards are shuffled, and cut to the dealer, who deals each player five cards by one at a time, as at whist. The deal being completed, the player to the dealer's left looks at his hand, and declares how many tricks he will play for (called "standing"). Some players make it compulsory for the eldest hand to declare one trick at least; but if this rule is not in force the eldest hand may decline to play, when he says "I pass." If the eldest hand passes, the next player to the left has a similar option of standing or passing, and so on all round. As soon as any one stands, the next player after him must either pass or stand for more tricks than the one before him, and so on all round. If all pass, the hand is not played, and the player to the dealer's left deals. Some players compel the dealer to play for at least one trick. The stand-hand plays against all the others. He has the first lead, and the first card he leads makes the trump suit. Each player plays one card at a time in rotation, as at whist, except that the played cards remain face upwards on the table in front of the persons playing them. The cards played one by each player constitute a "trick." The players must follow suit if able. If unable to follow suit a player may play any card he pleases. No one is obliged to head the trick nor to trump. If the stand-hand succeeds in making at least the number of tricks he stood for he wins; if not he loses. If he wins he receives from each of the other players the amount previously agreed on for each trick stood for; if he loses he similarly pays all the others. If any one declares "Nap," *i.e.*, that he will play for all five tricks, no subsequent player can stand. The hand is played as before. If the player declaring Nap wins he receives double stakes all round; if he loses he only pays single stakes all round.

Rules of Play.—There is no misdeal, and consequently no penalty for errors in dealing. If a card is exposed in dealing, or the cards are wrongly dealt, there must be a fresh deal, even if the hand has been partly played. Any one, except the stand-hand, playing out of turn, or exposing a card after the deal is completed, or playing with the wrong number of cards, has to pay a fine of the value of three tricks to the stand-hand, in addition to what he may lose if the hand is played out; and if the stand-hand loses the offender receives nothing If the stand-hand plays with the wrong number of cards, and wins, he receives nothing, and there is a fresh deal. If a player, not the stand-hand, revokes he has to pay the value of five tricks to the stand-hand, in addition to what he may lose on the hand. The cards are played over again from the point at which the revoke was made, and if the stand-hand loses the revoker receives nothing. If the stand-hand revokes he loses what he declared to play for. A player is entitled to be informed how many tricks were stood for, and how many tricks the stand-hand has made

NARA, the oldest of the successive capitals of Japan, is situated in the north of Sakai *ken* (province of Yamato), about 65 miles east of Ozaka, in 34° 4′ N. lat. and 135° 49′ E. long., on the slope of a range of picturesque hills, beautifully wooded, with cryptomerias, evergreen oaks, the rare *Podocarpus Nageia*, &c. From 710, when it was chosen as her residence by Gemmei Tenno, till 794, when Kioto was founded by Kuwammu Tenno, Nara was the chief seat of the mikados; and, as during that period Japanese art was in its early vigour, and was largely patronized by the Shinto and Buddhist religions, it rapidly became a great and sumptuous city. At present (though hardly a tenth of its former size) it has a population of about 21,500, living in 6000 houses; and in antiquarian interest it is hardly second to any place in the empire. The site of the old imperial palace, which stood about four miles from the town on the way to Ozaka, is now indicated only by a small Shinto temple; but about a mile off are the tombs of Gemmei Tenno and Gen-cho Tenno. Of the many religious buildings still extant, two especially demand attention—the Shinto temple of Kusuga and the Buddhist To-dai-ji (Great Temple of the East). The former was founded in 767 in the time of Sho-to-ku Tenno; and its Kami chapels with their rough red-painted log-work afford fine examples of primitive Japanese architecture. A rough wooden building constructed for storing the mikado's furniture in the 8th century is still extant, and among the articles accumulated within are many of those mentioned in the original inventory. In the temple-park are herds of tame deer (*Cervus shika*, Sieb.); and little images of deer and trinkets from deer's horn are the favourite charms purchased by the pilgrims. Within the enclosure stands a curious old trunk on which are growing the camellia, the cherry, the nandina, the wistaria, and what the Japanese call the seven-colour bush (nana-iro-iro ri). The To-dai-ji was begun by Shōmu Tenno in the 8th century, and was last restored in the 18th. At present the buildings enclose a quadrangle 520 feet by 620,—the south side being mainly occupied by the huge, ungainly, and no longer perpendicular hall containing the Dai Butsu, or colossal statue of Buddha. The casting of this wonderful piece of work was, after eight failures, accomplished in 749 by Takusho, an artist from Corea. On two occasions the head has been melted during the burning of the temple (1180 and 1567), and from 1567 to 1697 the statue stood exposed to the weather; but in the main it is marvellously perfect. The height of the figure is 55 feet, the face is 13 feet long, the ears 8, the nose 3, and the great halo has a diameter of 80 feet. On a hill to the east of the temple stands a bell-house with a monster bell, cast in 732, 13½ feet high, 9 feet across the mouth, and weighing 37 tons. Of the great Buddhist temple Ko-buku-ji, which was founded in 710, and burnt for the third time in 1717, there remains little save a five-storied pagoda 150 feet high, dating from 730.

NARBADA. See NERBUDDA.

NARBONNE, a city of France, chief town of an arrondissement in the department of Aude, lies 5 miles from the Mediterranean, on the Robine Canal, a branch of the Canal du Midi, which connects it with the port of La Nouvelle, and on the railway from Toulouse to Cette, 93 miles east-south-east of the former city, at the point where the line for Barcelona *via* Perpignan breaks off. The Robine Canal divides Narbonne into two distinct portions,

[1] Napoleon Eugène Louis born at Paris, March 16, 1856, killed in Zululand, June 1, 1879.

the *bourg* and the *cité*. The latter is one of the oldest and most interesting of French towns. The cathedral (St Just) is the third on the site, and dates from the close of the 13th century, when the choir (130 feet high) was built. Two towers were added in the 15th century. An unusual effect is produced by a double row of crenellation taking the place of balustrades on the roof of the choir chapels and connecting the pillars of the flying buttresses. Among the sepulchral monuments in the chancel may be noticed the alabaster tomb of Cardinal de Briçonnet, minister of state under Charles VIII. The chapter-house, of the 15th century, has a vaulted roof supported on four free pillars. From the top of the towers, 194 feet high, a magnificent view is obtained over the Narbonne plain, the valley of the Aude, the Montagne Noire, the Cevennes, the hills of La Clape, which lie between the city and the sea, the Canigou, and the Corbières. The apse of the cathedral was formerly joined to the fortifications of the archiepiscopal palace, and the two buildings are still connected by a mutilated cloister of the 14th and 15th centuries. On the front of the palace are three square towers of unequal height. Between the Tour des Télégraphes (1318), crenellated and turreted at the corners, and that of St Martial (1380), machicolated and pierced by Gothic openings, a new façade was erected in the style of the 15th century after the plans of Viollet-le-Duc. This portion of the building now serves as hôtel de ville, and its upper stories are occupied by the Narbonne museum, one of the best outside of Paris, containing pictures, pottery, nearly three thousand medals, and (in the old guard-room) a rich variety of Greek, Carthaginian, and Roman antiquities. The palace garden also contains many fragments of Roman work once built into the now dismantled fortifications; and the Musée Lapidaire in the Lamourguier buildings (formerly a Benedictine convent) has six hundred and twenty bas-reliefs and three hundred and twenty-three ancient inscriptions. The church of St Paul, though partly Romanesque, is in the main a striking and for the south of France a rare example of a building of the first half of the 13th century in the Gothic style of the north. It possesses some ancient Christian sarcophaguses and fine Renaissance wood carving. Narbonne has a good trade, especially in wine and spirituous liquors,—the surrounding country growing (at the rate of 120 gallons per acre) strong alcoholic wines, largely in demand for "fortifying" weaker vintages. As a matter of course this gives employment to large numbers of coopers; and besides there are in the town several verdigris factories, a sulphur refinery, and tanneries. The honey of Narbonne is famed throughout Europe. The population in 1881 was 29,134.

the crusade against the Albigenses spared the city, but the archbishopric was seized by the pope's legate Amaury, who took the title of duke of Narbonne. Simon de Montfort, however, deprived him of this dignity, receiving from Philip Augustus the duchy of Narbonne along with the county of Toulouse. By his expulsion of the Jews Philip the Fair hastened the decay of the city; and about the same period the Aude, which had formerly been diverted by the Romans, ceased to flow towards Narbonne and the harbour was silted up, to the further disadvantage of the place. United to the French crown in 1507, Narbonne was enclosed by a new line of walls under Francis I., but having ceased to be a garrison town it had the last portions of its ramparts demolished in 1870.

NARBOROUGH, SIR JOHN (*ob.* 1688), naval commander, was descended from an old Norfolk family. He received his commission in 1664, and in 1666 was promoted lieutenant for gallantry in the action with the Dutch fleet off the Downs in June of that year. After the peace he was chosen to conduct a voyage of exploration in the South Seas. He set sail from Deptford on the 26th November 1669, and entered the Straits of Magellan in October of the following year, but returned home in June 1671 without accomplishing his original purpose. A narrative of the expedition was published at London in 1694 under the title *An Account of several late Voyages and Discoveries to the South and North*. During the second Dutch war Narborough was second captain of the lord high-admiral's ship the "Prince," and conducted himself with such conspicuous valour at the battle of Solebay (Southwold Bay) in May 1672 that he won special approbation, and shortly afterwards was made rear-admiral and knighted. In 1675 he was sent to suppress the Tripoline piracies, and by the bold expedient of despatching gunboats into the harbour of Tripoli at midnight and burning the ships he induced the dey to agree to a treaty. Shortly after his return he undertook a similar expedition against the Algerines. In 1680 he was appointed commissioner of the navy, an office he held till his death in 1688. He was buried at Knowlton church, Kent, where a beautiful marble monument has been erected to his memory.

NARCISSUS, a genus of bulbous plants belonging to the family *Amaryllidaceæ*. There are twenty or thirty wild forms, natives of central Europe and the Mediterranean region, while one extends through Asia to Japan. From these, or rather from some of these, by cultivation and hybridization, have arisen the very numerous forms which adorn our gardens in spring (see vol. xii. p. 257). The most interesting feature botanically is the "corona," or "cup," which springs from the base of the flower-segments. This gives the special character to the flower, and the members of the genus are classified according to the length of this organ as compared with that of the segments. Much has been written as to the real nature of this cup, but the most probable supposition is that it does not, as once supposed, represent one or more rows of modified stamens, but is simply an excrescence or "enation" from the mouth of the flower-tube, and probably is in some way connected with the fertilization of the flowers by insect agency.

NARCOTICS are substances having the physiological action, in a healthy animal, of producing lethargy or stupor, which may pass into a state of profound coma or unconsciousness along with complete paralysis, terminating in death. Certain substances of this class are used in medicine for the relief of pain, and are then called anodynes, whilst another group produce profound sleep, and are consequently known as hypnotics. In one sense, anæsthetics, such as chloroform and ether, may be held to be narcotics, but, as they are usually volatile substances causing unconsciousness for a comparatively short time, they are conveniently separated from the true narcotics, the effects of which are much more lasting. These distinctions are to a great extent artificial, as it is evident that a substance capable of producing partial insensibility

to pain, or sleep, will inevitably in larger doses cause profound coma ending in death. Hence we find the same substances sometimes classed as anodynes and at other times as hypnotics. For example, small doses of opium, or of one or other of its preparations, relieve pain, whilst larger doses act as hypnotics, causing deep sleep passing into coma. As examples of anodynes, we have opium and some of the alkaloids in it, *Cannabis indica* or Indian hemp, belladonna and its alkaloid atropia, hyoscyamus or henbane and its alkaloid hyoscyamia, and the anæsthetics properly so called, such as chloroform, ether, ethidene, &c. The hypnotics are such substances as opium and its alkaloids, chloral hydrate, hyoscyamus, lactucarium (obtained from *Lactuca virosa*, the strong-scented lettuce), and preparations of *Humulus Lupulus* (the common hop), such as inhalations of the steam of infusions, or hop-pillows. In addition we may group as narcotics certain substances which cause not only narcotism, but also the specific effect

Name of Substance.	Name of Plant.	Common Names	Alkaloids	Physiological Action.	Poisonous Dose.	Treatment of Case of Poisoning
Opium.	Inspissated juice of *Papaver somniferum*, or poppy.	Opium.	In 100 parts of fine opium 10 parts of morphia, 6 of narcotina, 1 of paraverina, ·15 of thebaia or paramorphia, ·01 of codeia, ·01 of meconia, ·02 of narceia, and 4 of meconic acid.	Described in text. Acts on all classes of animals. May cause convulsions from increased activity of reflex centres in the spinal cord, especially in animals having small brains. Causes slowing of heart's action by stimulation of inhibitory nerves of heart. Destroys the action of the respiratory centres in medulla. Stimulates oculo-motor centres, and hence causes contraction of pupil	Varies according to habit. Opium eaters can take 20 to 30 grains with impunity. 1 to 3 grains produce well-marked symptoms in ordinary persons. Medicinal dose for adult is $\frac{1}{4}$ to 2 grains.	Evacuate the stomach by an emetic or by the stomach-pump. Give at once a large table-spoonful of mustard in a tumblerful of tepid water, and repeat in a quarter of an hour if necessary; to be followed by a powder containing 30 grains of sulphate of zinc and 20 grains of ipecacuanha powder. Keep up respiration by constantly inducing the patient to breathe voluntarily. Cause the patient to walk about, and endeavour to keep him awake. Give him very strong infusions of coffee or tea, especially green tea. In the last stages use artificial respiration.
Morphia	From opium. See above.	Morphia.	Morphia, $C_{17}H_{19}NO_3H_2O$, employed as hydrochlorate of morphia or acetate of morphia.	Similar to opium. Paraverina, narceia, meconia, cryptopia, codeia, and thebaia or paramorphia have all actions of a narcotic character, but codeia and thebaia have more of an exciting action and little of a narcotic action.	Varies according to habit 2 to 3 grains by stomach dangerous $\frac{1}{2}$ of a grain for an adult man or $\frac{1}{10}$ for an adult woman is the largest safe dose when injected under the skin	Same as for opium.
Indian Hemp	Alcoholic extract of *Cannabis sativa*, as it grows in India and in America.	Indian hemp. *Gunjah* is the dried plant sold in Calcutta bazaars for smoking; *Churrus* is the resinous exudation of the epidermis; *Hashish* is an Arabian preparation.	No alkaloid has been separated. The resin is the active preparation	Exhilaration, great mental excitement, with pleasant and often gorgeous visions; a state of ecstasy, with loud laughter; loss of sense of time, or a feeling as if pleasurable sensations were infinitely prolonged. Pupils dilated. Loss of strength, drowsiness, sleep, coma.	Varies much with different specimens of resin $\frac{1}{2}$ of a grain may cause marked effects. 2 to 3 grains dangerous.	Seldom fatal. If a large dose has been taken, use emetic of mustard and water, or stomach-pump; after this keep the patient quiet, allay excitement, and if symptoms of depression come on small doses of alcohol are useful.
Belladonna.	Leaves and roots of *Atropa Belladonna*.	Deadly nightshade	Atropia.	See Atropia.	... ...	... ...
Atropia	*Atropa Belladonna*.	Atropine.	Atropine, $C_{17}H_{23}NO_3$, employed as sulphate of atropine.	See description in text. Increased frequency of pulse, with rise of arterial pressure. Fall of blood pressure with very large doses. Paralyses the inhibitory action of the vagus nerve, so that stimulation of this nerve during atropine poisoning does not cause slowing of heart. Small doses cause contraction of capillary vessels, thus acting as a stimulant to vaso-motor centres. Destroys the excitability of motor nerves passing to muscles generally, thus producing inability to move. Weakens and finally abolishes the reflex excitability of the spinal cord. Large doses weaken action of motor nerves concerned in the movements of respiration. Suppresses secretion of the mucous and salivary glands, probably by paralysing secretory nerves. Large doses lower the temperature of the body. Causes dilatation of pupil, lessened intra-ocular pressure, and paralysis of accommodation.	80 grains of root have caused death. Sometimes the medicinal extract of belladonna is so weak that a dose of 2 drachms may not be fatal. $\frac{1}{16}$ or $\frac{1}{5}$ of a grain of atropine may cause alarming symptoms, and half a grain would almost certainly be fatal.	Same treatment as for opium poisoning. The object aimed at is to prevent absorption of the poison by the free use of emetics. External stimulation by bathing the feet in mustard and water, by rubbing or kneading the skin, along with the free use of tannic acid suspended in water, are the best remedial measures. There is often retention of urine. This must be relieved by the catheter
Stramonium	Leaves and seeds of *Datura Stramonium*.	Jamestown weed, thorn-apple.	Daturia, identical with atropia	Same as belladonna and atropia.	Not ascertained. Children have been poisoned by eating the seeds.	Treatment the same as for belladonna and atropia.
Hyoscyamus	Leaves and seeds of *Hyoscyamus niger*.	Henbane.	Hyoscyamia. $C_{15}H_{23}NO_3$.	Almost identical with atropia. There is even greater excitement than in cases of belladonna poisoning, indicating a stronger action on the cerebrum. The action of the heart is first stimulated as with atropia, but it is afterwards much depressed, as shown by the lessening number of pulse beats. Pupil dilated. Mouth dry and parched.	$\frac{1}{16}$ of a grain of hyoscyamin will cause appreciable effects $\frac{1}{30}$ of a grain causes sleepiness, dryness of mouth, and dilatation of pupil. $\frac{1}{30}$ causes quickening of heart's action, and $\frac{1}{12}$ will produce first quickening and then slowing of the heart. The half of a grain would be dangerous	Treatment the same as for belladonna and atropia
Hops	The dried strobiles of the female plant of *Humulus Lupulus*.	The hop or hop-vine.	Lupulina.	A feeble narcotic, causing, when infusions are taken freely heaviness, and perhaps sleep	Not regarded as a poison	... ...

of dilatation of the pupil of the eye, and disorder of the mechanism of focussing the eye for various distances, resulting in dimness and confusion of vision. Such are sometimes called mydriatics (μυδριάσις, dimness of sight); they embrace belladonna, henbane, stramonium, cryptopia (one of the alkaloids in opium), and Indian hemp.

All of these substances act on the nervous system, and, although the physiological action of each is characteristic, there are many symptoms common to the whole group; indeed the course of action of all shows three well-defined stages:—(1) there is first a period of apparent exaltation of function; (2) this is followed by a period of diminution and perversion of functional activity; and (3) there is a time of loss of function, in which there is profound coma and paralysis. This is well illustrated by a description of the symptoms caused by opium. A small dose not unfrequently acts as a stimulant; there is a sense of vigour, a capability of severe exertion, and an endurance of labour without fatigue. A larger dose often exerts a calming influence, with a dreamy state in which images and ideas pass rapidly before the mind without fatigue, and often in disorder and without apparent sequence; time seems to be shortened as one state of consciousness quickly succeeds another, and there is a pleasant feeling of grateful rest. This is succeeded by sleep which, according to the strength of the dose and the idiosyncracy of the person, may be light and dreamy, or like natural profound sleep, or deep and heavy, passing into stupor or coma. From this a person may awaken with a feeling of depression, languor, or wretchedness, often associated with sickness, headache, and vomiting. If a person do not thus awaken, and the dose be large, there is the condition of deep coma. The pupils are strongly contracted, the face usually flushed and often purplish in hue, the skin dry and warm, respiration deep and slow, often with the rattle in the throat called stertorous breathing; the pulse is slow, strong, and compressible under the finger; and there is deep unconsciousness, from which, however, the person may sometimes be aroused by shaking or shouting, and into which he at once relapses when left to himself. This condition is succeeded by one of even deeper prostration. The person cannot be aroused; the pupils may now become somewhat dilated, especially on the approach of death; the countenance has a death-like aspect, and a bluish-white tint; the pulse quickens and becomes smaller, and more and more feeble; and the skin is covered with a cold clammy sweat. The vital functions are reduced to the lowest ebb, and death then occurs from failure of respiration. Such a train of symptoms is called narcotism. These general symptoms are of course largely modified by the amount of the dose. If it be very large, the person may pass very quickly into the deeply comatose stage.

A somewhat different mode of action is illustrated by the physiological effects of belladonna, or of its alkaloid atropine or atropia. A small dose causes dryness of the throat and mouth, dilatation of the pupils, dimness of vision except for distant objects, and often double vision. The pulse becomes quick, rising, in an adult, from 80 to 120 or 160 beats per minute; and there is often a bright red flush over the skin. The intellectual powers are at first acute and strong, but they soon become confused. There is giddiness, confusion of thought, excitement, a peculiar talkative wakeful restiveness, in which the person shows that his mind is occupied by a train of fancies or is haunted by visions and spectres. Often there is violent delirium before sleep comes on. The sleep after a large dose deepens into stupor, with great muscular prostration or paralysis. During all the time the pupils are widely dilated. Death occurs from failure both of the heart's action and of respiration.

The chief facts regarding the true narcotics are briefly summarized in the accompanying table.

Conium or hemlock (the leaves and the fruit of *Conium maculatum*) and its alkaloid conia are sometimes erroneously classed as narcotics. These substances act more in the way of depressing or weakening muscular activity, by influencing the motor nerves, or the nerve-endings in the muscles, and they have no effect on sensory nerves and sensory centres. Neither is aconite a true narcotic (see ACONITE).

Hydrate of chloral has since 1872, when it was introduced as a therapeutic agent by Dr Oscar Liebreich of Berlin, come into great favour as an anodyne and narcotic. It is ethylic aldehyde in which 3 atoms of chlorine are substituted for 3 atoms of hydrogen; thus:—

$$\underset{\text{Aldehyde.}}{C_2H_4O} + \underset{\text{Chlorine.}}{6Cl} = \underset{\text{Chloral.}}{C_2HCl_3O} + \underset{\text{Hydrochloric acid.}}{3HCl}.$$

The formula for the hydrate is $C_2HCl_3O.2HO_2$. In small doses, say 10 to 20 grains, chloral is a pure hypnotic, and the sleep obtained is quiet and refreshing. In larger doses it is narcotic, abolishing thought and motor power, with profound coma. Respiration is much enfeebled, and the pulse becomes small and weak. The pupils are widely dilated. It is not uniform in its action, so that occasionally death may occur after a comparatively small dose, even in persons who have been in the habit of taking the medicine. For this reason, the habit of taking chloral without medical advice, and of taking it frequently, is to be strongly deprecated. An allied substance called croton-chloral hydrate ($C_8H_3Cl_3O_2.2HO$) has no hypnotic properties, but is of use when applied externally for severe neuralgia of the face, due to affections of the fifth cranial nerve (*tic douloureux*).

Narcotics are used in medicine for various purposes. (1) *To relieve pain.* The best one for this purpose is opium, either in the solid form or as laudanum (tincture of opium). It is most useful in cases of spasmodic pain. (2) *To cause sleep.* In some cases opium may be useful for this purpose; but it causes disorder of the digestive functions, and there is the further danger of producing the "opium habit," a vice ruinous alike to body and mind. On the whole hydrate of chloral is the best and safest hypnotic, but it is not without its dangers, and it ought not to be taken except under medical advice. (3) *To allay irritation.* Where there is increased sensibility, with continued irritating though not severe pain in any part, opium or hyoscyamus may be used with benefit. (4) *To cause dilatation of pupil.* For this purpose, solutions of atropine are in constant use by ophthalmic surgeons. A few drops of solution of atropine, or a soluble disk containing atropine, introduced into the eye, cause dilatation of the pupil and diminished tension in the eyeball, at the same time soothing pain. (5) *To arrest secretion.* For this purpose opium, or belladonna, and atropine are especially useful. Small doses of atropine are given to arrest secretion in cases of profuse salivation, and extract of belladonna applied to the skin is used for stopping the secretion of milk from the mammary gland. (J. G. M.)

NARD. See SPIKENARD.

NARSES, an officer in the household of Justinian, who was charged with the reconquest and government of Italy, is one of the most important historical figures of the 6th century. He was a eunuch, but we are nowhere distinctly informed that he was of servile origin. A native of Persarmenia (that is to say, of that portion of Armenia which was allotted to Persia by the partition of 384), he may have been prepared and educated by his parents for service in an Oriental court. If the statement that he died at the age of ninety-five be correct, he was born about the year 478. He was probably brought young to Constantinople, and attained a footing in the *officium* of the grand chamberlain. From a subordinate place he rose in course of time to be one of the three (spectabiles) "chartularii," a position implying some literary attainment, and involving the custody of the archives of the household. Hence, probably in middle life, he became "præpositus sacri cubiculi," an "illustris," and entitled along with the prætorian prefects and the generals to the highest rank at the imperial court. In this capacity, in 530, he received into the emperor's obedience another Narses, a fellow-countryman as well as namesake, together with his two brothers Aratius and Isaac. These Persarmenian generals, having formerly fought under the standard of Persia, now in consequence of the successes of Belisarius transferred their allegiance to the emperor,

came to Constantinople, and received costly gifts from the great minister.

In the year 532 the celebrated insurrection known as the Nika broke out in Constantinople, when for some hours the throne of Justinian seemed doomed to overthrow. It was saved partly by the courage of his wife, Theodora, and partly by the timely prodigality of Narses, who stole out into the capital, and with large sums of money bribed the leaders of the "blue" faction (which was aforetime loyal to the emperor) to shout as of old "Justiniane Auguste Tu Vincas."

The African and Italian wars followed (533–534, 535–554; see JUSTINIAN, vol. xiii. p. 797). In the fourth year of the latter war the splendid successes of Belisarius, who with a handful of troops had conquered the better part of Italy, reoccupied Rome, and held it against 150,000 Goths, vainly besieging it for 374 days, had awakened both joy and fear in the heart of his master. Reinforcements amounting to 10,000 men were sent into Italy, and Narses the eunuch was placed at their head. Belisarius understood that Narses came to serve under him like any other officer of distinguished but subordinate rank, and he received a letter from Justinian which seemed to support this conclusion. But the friends of Narses continually plied him with suggestions that he, a great officer of the household, in the secrets of the emperor, had been sent to Italy, not to serve as a subaltern, but to hold independent command and win military glory for himself. The truth probably lay between the two. Justinian could not deprive his great general of the supreme command, yet he wished to have a very powerful emissary of the court constantly at his side. He would have him watched but not hampered.

The two generals met (538 A.D.) at Fermo on the Adriatic coast. The first interference of Narses with the plans of Belisarius was beneficial. John, one of the officers highest in rank under Belisarius, had pressed on to Rimini, contrary to the instructions of his chief, leaving in his rear the difficult fortress of Osimo untaken. His daring march had alarmed the Goths for Ravenna, and induced them to raise the siege of Rome; but he himself was now shut up in Rimini, and on the point of being forced by famine to surrender. Belisarius and his followers were prepared to let him pay the penalty of his rashness and disobedience. But his friend Narses so insisted on the blow to the reputation of the imperial arms which would be produced by the surrender of Rimini that he carried the council of war with him, and Belisarius had to plan a brilliant march across the mountains, in conjunction with a movement by the fleet, whereby Rimini was relieved while Osimo was still untaken. When Belisarius and John met, the latter ostentatiously thanked Narses and Narses alone for his preservation.

His next use of his authority was less fortunate. Milan, which was holding out for the Romans, was also hard pressed by famine. The two generals who were sent to relieve it loitered disgracefully over their march, and when Belisarius wished to despatch further reinforcements the commanders of these new troops refused to stir till Narses gave them orders. Belisarius wrote to the eunuch pointing out the necessity of unity of purpose in the imperial army. At length, grudgingly, Narses gave his consent, and issued the required orders; but it was too late. Milan had been compelled by extremity of famine to surrender, and with it the whole province of Liguria fell into the hands of the enemy. This event forced Justinian to recognize the dangers of even a partially divided command, and he recalled Narses to Constantinople.

Twelve years elapsed before Narses returned to Italy. Meanwhile there had been great vicissitudes of fortune both for the Romans and the Goths. Italy, which appeared to have been won by the sword of Belisarius, had been lost again by the exactions and misgovernment of Alexander. The young and gallant Totila had raised up a new army, had more than kept Belisarius at bay in five difficult campaigns (544–548), and now held nearly all the country. Belisarius, however, in this his second series of campaigns, had never been properly seconded by his master. In the spring of 552 Narses set sail from Salona on the Dalmatian coast with a large and well-appointed army. It was a Roman army only in name. Lombards, Heruli, Huns, Gepidæ, and even Persians followed the standard of Narses, men equal in physical strength and valour to the Goths, and inspired by the liberal pay which they received and by the hope of plunder.

The eunuch seems to have led his army round the head of the Adriatic Gulf. By skilfully co-operating with his fleet he was able to cross the rivers of Venetia without fighting the Gothic general Teias, who intended to dispute their passage. Having mustered all his forces at Ravenna, he marched southward. He refused to be detained before Rimini, being determined to meet the Gothic king as soon as possible with his army undiminished. The occupation of the pass of Furlo (Petra Pertusa) by the Goths prevented his marching by the Via Flaminia, but, taking a short circuit, he rejoined the great road near Cagli. A little further on, upon the crest of the Apennines, he was met by Totila, who had advanced as far as Tadini (which Procopius calls Taginas). Parleys, messages, and harangues by each general followed. At length the line of battle was formed, and the Gothic army (probably greatly inferior in number to the Byzantine) was hopelessly routed, the king receiving a mortal wound as he was hurrying from the battlefield.

With Totila fell the last hopes of the Gothic kingdom of Italy. The brave young Teias, who was proclaimed his successor, protracted for a few months a desperate resistance in the rocky peninsula of Castellamare, overlooking the Bay of Naples. At length want of provisions forced him into the plain, and there by the river Sarno, almost in sight of Pompeii, was fought (553) a battle which is generally named from the overlooking range of Mons Lactorius (Monte Lettere). The actual site of the battle, however, is about half a mile from the little town of Angri, and its memory is still vaguely preserved by the name *Pozzo dei Goti* (Well of the Goths). In this battle Teias was killed. He was the last king of the Ostrogoths.

The task of Narses, however, was not yet ended. By the invitation of the Goths an army of 75,000 warlike Alemanni and Franks, the subjects of King Theudibert, crossed the Alps under the command of two Alemannic nobles, the brothers Leuthar and Butilin (553). The great strategic talents of Narses were shown even more conspicuously in this than in his previous and more brilliant campaigns. Against the small but gallant bands of Totila and Teias he had adopted the policy of rapid marches and imperative challenges to battle. His strategy in dealing with the great host from Gaul was of the Fabian kind. He kept them as long as he could north of the Apennines, while he completed the reduction of the fortresses of Tuscany. At the approach of winter he gathered his troops into the chief cities and declined operations in the field, while the Alemannic brothers marched through Italy killing and plundering. When the spring of 554 appeared, Leuthar with his half of the army insisted on marching back to Gaul, there to deposit in safety the plunder which they had reaped. In an unimportant engagement near Pesaro he was worsted by the Roman generals, and this hastened his northward march. At Ceneda in Venetia he died of a raging fever. Pestilence broke out in his army, which if not absolutely annihilated thereby was so wasted as to be incapable of further opera-

tions in Italy. Meanwhile his brother Butilin, whose army was also suffering grievously from disease, partly induced by too free indulgence in the grapes of Campania, encamped at Casilinum, the site of modern Capua. Here, after a time, Narses accepted the offered battle. The barbarians, whose army was in the form of a wedge, pierced the Roman centre. But by a most skilful manœuvre Narses contrived to draw his lines into a curve, so that his mounted archers on each flank could aim their arrows at the backs of the troops who formed the other side of the Alemannic wedge. They thus fell in whole ranks by the hands of unseen antagonists. Soon the Roman centre, which had been belated in its march, arrived upon the field and completed the work of destruction. Butilin and his whole army were destroyed, though we need not accept the statement of the Greek historian (Agathias, ii. 9) that only five men out of the barbaric host of 30,000 escaped, and only eighty out of the Roman 18,000 perished (554).

The only other important military operation of Narses which is recorded—and that indistinctly—is his defeat of the Herulian king Sindual, who had served under him at Capua, but who subsequently revolted, was defeated, taken captive, and hanged by the eunuch's order (565). In the main the thirteen years after the battle of Capua (554–567) were years of peace, and during them Narses ruled Italy from Ravenna with the title of prefect.[1] He rebuilt Milan and other cities destroyed in the Gothic war; and two inscriptions on the Salarian bridge at Rome have preserved to modern times the record of repairs effected by him in the year 564.[2]

His administration, however, was not popular. The effect of the imperial organization was to wring the last *solidus* out of the emaciated and fever-stricken population of Italy, and the belief of his subjects was that no small portion of their contributions remained in the eunuch's private coffers. At the close of 565 Justinian died, and a deputation of Romans waited upon his successor Justin II., representing that they found "the Greeks" harder taskmasters than the Goths, that Narses the eunuch was determined to reduce them all to slavery, and that unless he were removed they would transfer their allegiance to the barbarians. This deputation led to the recall of Narses, which took place in 567, and was accompanied, according to a somewhat late tradition, by an insulting message from the empress Sophia, who sent him a golden distaff, and bade him, as he was not a man, go and spin wool in the apartments of the women. "I will spin her such a hank," Narses is represented as saying, "that she shall not find the end of it in her lifetime"; and forthwith he sent messengers to the Lombards in Pannonia, bearing some of the fruits of Italy, and inviting them to enter the land which bore such goodly produce. Hence came the invasion of Alboin (568), which wrested the greater part of Italy from the empire, and changed the destinies of the peninsula.[3]

[1] Gibbon's statement that Narses was "the first and most powerful of the exarchs of Ravenna" is more correct in substance than in form. The title of exarch does not appear to be given to Narses by any contemporary writer. He is always "Præfectus Italiæ," "Patricius," or "Dux Italiæ," except when he bears the style of his former offices in the imperial household, "Ex-Præpositus [Cubiculi]" or "Chartularius" (compare Rubeus, *Historia Ravennates*, p. 175).

[2] See Gruter, p. 161.

[3] This celebrated story seems to be unknown to strictly contemporary authors. We find no hint of it in Agathias (who wrote between 556 and 582), Marius (532–596), or Gregory of Tours (540–594). The possibly contemporary *Liber Pontificalis* and Isidore of Seville (560–636) hint at the invitation to the Lombards. Fredegarius (so-called), who probably wrote in the middle of the 7th century, and Paulus Diaconus, towards the close of the 8th, supply the saga-like details, which become more minute the further the narrators are from the actors. On the whole, the transaction, though it is too well vouched for to allow us to dismiss it as entirely fabulous, cannot take its place among the undoubted facts of history.

Narses, who had retired to Naples, was persuaded by the pope (John III.) to return to Rome. He died there about 573, and his body, enclosed in a leaden coffin, was carried to Constantinople and buried there. Several years after his death the secret of the hiding-place of his vast stores of wealth is said to have been revealed by an old man to the emperor Tiberius II., for whose charities to the poor and the captives they furnished an opportune supply.

Narses was short in stature and lean in figure. His freehandedness and affability made him very popular with his soldiers. Evagrius tells us that he was very religious, and paid special reverence to the Virgin, never engaging in battle till he conceived that she had given him the signal. Our best authorities for his life are his contemporaries Procopius and Agathias. For the period after 555 we have to depend chiefly on fragmentary notices in the authors whose names have been mentioned above. (T. H.)

NARSINHPUR,[4] a district in the chief-commissionership of the Central Provinces, India, lying between 22° 45′ and 23° 15′ N. lat. and between 78° 38′ and 79° 38′ E. long., bounded on the N. by Bhópál state and by Ságar, Damoh, and Jabalpur districts, E. by Seoní, S. by Chhindwárá, and W. by Hoshangábád. It forms a portion of the upper part of the Nerbudda valley. The first of those wide alluvial basins which, alternating with rocky gorges, give so varied a character to the river's course opens out just below the famous marble rocks in Jabalpur, and extends westward for 225 miles, including the whole of Narsinhpur, together with the greater part of Hoshangábád. The Sátpurá hills to the south are here a generally regular range, nowhere more than 500 feet above the plain, and running almost parallel to the river, at a distance of 15 or 20 miles. In the intervening valley, the rich level of black wheat land is seldom broken, except by occasional mounds of gravel or nodular limestone, which afford serviceable village sites. Along the foot of the boundary hills the alluvium gives way to belts of red gravelly soil, rice and sugar-cane take the place of wheat, and forest trees that of mango groves.

The population in 1880 was 365,173, the Hindus numbering 305,562, and the Mohammedans only 13,425. The most numerous of the aboriginal tribes are the Gonds (46,645). Only two towns contained upwards of 5000 inhabitants—Narsinhpur (7816) and Gadarwára (6553). Of the area of 1916 square miles, 974 were under cultivation in 1882. Wheat is the staple crop, occupying 280,898 acres; other food grains took up 245,797 acres; cotton, 46,204 acres; and sugar-cane, 2271 acres. Rotation of crops is not practised, but when the soil shows signs of exhaustion gram or some other pulse is substituted for two or three years. Cultivators dare not leave their lands fallow, even for a single year, for the ground would be immediately occupied by rank *káns* grass, which no exertions can eradicate till it has run its course of about ten years. The principal export is cotton. Coal mining is carried on at Mohpání, Sihora, and Setarewa; and iron-ore of excellent quality is smelted in large quantities at Tendúkherá and elsewhere there being 38 mines in operation in 1882.

NARVAEZ, PÁNFILO DE (*c.* 1480–1528), Spanish adventurer, was an hidalgo of Castile, born at Valladolid about 1480. He was one of the subordinates of Velazquez in the reduction of Cuba, and, after having held various posts under his governorship, was put at the head of the force sent to the Aztec coast to compel Cortes to renounce his command; he was surprised and defeated, however, by his abler and more active compatriot at Cempoalla, and made prisoner with the loss of an eye (1520). After his return to Spain he obtained from Charles V. a grant of Florida as far as the River of Palms; sailing in 1527 with five ships and a force of about 600 men, he landed, probably near Tampa Bay, in April 1528, and, striking inland with some 300 of his followers, reached "Apalache" on June 25. The prospects of fabulous wealth which had sustained them in their difficult and perilous journey having proved illusory, a return to the coast was determined, and the Bahia de los Caballos, at or near St Mark's, was

[4] Narsinhpur is also the name of a petty native state in Orissa

reached in the following month. Having built two boats, the small remnant company sailed hence for Mexico on September 22, but the vessel which carried Narvaez was driven to sea in a storm and perished. His lieutenant, Cabeza de Vaca, with three others who ultimately reached land, made his way across Texas to the Gulf of California.

NARVAEZ, RAMON MARIA (1800–1868), Spanish soldier and statesman, was born at Loja, Granada, on August 5, 1800, entered the army at an early age, and saw active service under Mina in Catalonia in 1822. In 1823 the French invasion caused him to retire into private life, whence he re-emerged in 1833, speedily attaining the rank of colonel. He achieved great popularity by his victory over Gomez, the Carlist general, near Arcos, in November 1836, and after clearing La Mancha of brigands by a vigorous policy of suppression in 1838 he was appointed captain-general of Old Castile, and commander-in-chief of the army of reserve. In 1840, for the part he had taken at Seville in the insurrection against Espartero, he was compelled to take refuge in France, where, in conjunction with Maria Christina, he planned the expedition of 1843 which led to the overthrow of his adversary. In 1844 he became prime minister, and was created field-marshal and duke of Valencia, but his policy was too reactionary to be tolerated long, and he was compelled to quit office in February 1846. He now held the post of ambassador at Paris, until again called to preside over the council of ministers in 1847; but misunderstandings with Maria Christina led to his resignation in the following year. His ministry succeeded that of O'Donnell for a short time in 1856–57, and he again returned to power for a few months in 1864–65. He once more replaced O'Donnell in July 1866, and was still in office when he died at Madrid on April 23, 1868.

NARWHAL, an animal of the order *Cetacea* (see MAMMALIA, vol. xv. p. 398), belonging to the genus *Monodon*, of which there is but one species known, *M. monoceros* of Linnaeus. It is included in the family *Delphinidae* or Dolphins, and closely resembles the *Beluga* or White Whale in all points of its structure except its dentition, which presents most anomalous characters. In the adult there are but two teeth present, both in the upper jaw. They lie horizontally side by side, and in the female they remain throughout life concealed in cavities of the bone, so that this sex is practically toothless. In the male the right tooth usually remains similarly concealed and abortive, but the left is immensely developed, attaining a length equal to more than half that of the entire animal. In a narwhal 13 feet long, from snout to end of tail, the external portion of the tusk may measure 6 or 7 and occasionally 8 feet in length. It projects horizontally forwards from the head in the form of a cylindrical or slightly tapering, pointed tusk, composed of ivory, with a central cavity reaching almost to the apex, without enamel, and with the surface marked by spiral grooves and ridges, running in a sinistral direction. Occasionally both left and right tusks are developed, in which case the direction of the grooves is not reversed, but the same in both. No instance has ever been met with of the complete development of the right tusk associated with a rudimentary condition of the left. In very young animals several small additional teeth, irregular in number and position, are present, but these usually disappear soon after birth.

The head is rather short and rounded; the fore limbs or paddles are small and broad compared with those of most dolphins; and (as in *Beluga*) the median dorsal fin, found in nearly all other members of the group, is wanting or replaced by a low ridge. The general colour of the surface is dark grey above and white below, but variously marbled and spotted with different shades of grey.

The narwhal is essentially an Arctic animal, frequenting the icy circumpolar seas, and but rarely seen south of 65° N. lat. Three instances have, however, been recorded of its occurrence on the British coasts, one in the Firth of Forth in 1648, one near Boston in Lincolnshire in 1800, while a third, which entangled itself among rocks in the Sound of Weesdale, Shetland, in September 1808, is described by Fleming in the *Memoirs of the Wernerian Society*, vol. i. Like most other cetaceans it is gregarious in its habits, being usually met with in "schools" or herds of fifteen or twenty individuals. Its food appears to be various species of cephalopods, small fishes and crustaceans. The purpose served in the animal's economy by the wonderfully developed asymmetrical tusk—or "horn," as it is commonly but incorrectly called—is not known. As it is present only in the male sex, no function essential to the well-being of the individual, such as the procuring of sustenance, can be assigned to it, but it must be looked upon as belonging to the same category of organs as the antlers of deer, and perhaps may be applied to similar purposes. Very little is, however, known of the habits of narwhals. Scoresby describes them as "extremely playful, frequently elevating their horns and crossing them with each other as in fencing." They have never been known to charge and pierce the bottom of ships with their weapons, as the swordfish, a totally different animal, often does. The name "Sea Unicorn," sometimes applied to the narwhal, refers to the resemblance of its tusk to the horn represented as projecting from the forehead of the fabled unicorn. The ivory of which the tusk is composed is of very good quality, but, owing to the central cavity, is only fitted for the manufacture of objects of small size. The entire tusks are sometimes used for decorative purposes, and are of considerable, though very fluctuating, commercial value. (W. H. F.)

NASH, RICHARD (1674–1762), better known as "Beau Nash," was born at Swansea, 18th October 1674. He was descended from an old family of good position, but his father from straitened means had become partner in a glass business. Young Nash was educated at Caermarthen grammar school and at Jesus College, Oxford. He obtained a commission in the army, which, however, he soon exchanged for the study of law at the Middle Temple. "Here," it is said, "he went to the very summit of second-class luxury," and among "wits and men of pleasure" he came to be accepted as an authority in regard to dress, manners, and style. When the members of the Inns of Court entertained William III. after his accession, Nash was chosen to conduct the pageant. This duty he performed so much to the satisfaction of the king that he was offered knighthood, but he declined the honour unless accompanied by a pension. As the king did not take the hint, Nash found it necessary to turn gamester. The pursuit of his calling led him in 1704 to Bath, where he had the good fortune almost immediately to succeed Captain Webster as master of the ceremonies. His qualifications for such a position were unique, and under his conventional authority reforms were introduced which rapidly secured to Bath a leading position as a fashionable watering-place. He drew up a new code of rules for the regulation of balls and assemblies, abolished the habit of wearing swords in places of public amusement, induced gentlemen to adopt shoes and stockings in parades and assemblies instead of boots, reduced refractory chairmen to submission and civility, and introduced a tariff for lodgings. Through his exertions a handsome assembly-room was also erected, and the streets and public buildings were greatly improved. Nash adopted an outward state corresponding to his nominal dignity. He wore an immense white hat as a sign of office, and a dress adorned

with rich embroidery, and drove in a chariot with six greys, laced lackeys, and French horns. Notwithstanding his vanity and impertinence, the tact, energy, and superficial cleverness of Nash won him the patronage and notice of the great, while the success of his ceremonial rule, as shown in the increasing prosperity of the town, secured him the gratitude of the corporation and the people generally. When the Act of Parliament against gambling deprived him of an easy though uncertain means of subsistence, the corporation granted him a pension of six score guineas a year, which, with the sale of his snuff boxes and other trinkets, enabled him to support a certain faded splendour till his death on February 3, 1761. He was honoured with a public funeral at the expense of the town.

A *Life of Richard Nash*, by Goldsmith, was published anonymously at London in 1762, has been frequently reprinted, and is now included in the editions of Goldsmith's collected works. See also *London Magazine*, vol xxxi., and a paper on "The Monarch of Bath" in *Blackwood's Magazine*, vol. xlviii.

NASH, THOMAS (*c.* 1564–1601), poet, playwright, and pamphleteer, was one of the most notable literary celebrities in the brilliant last decade of the reign of Elizabeth. The exact years of his birth and death have not been ascertained; but from the fact that he proceeded B.A. (St John's, Cambridge) in 1585 it has been conjectured that he was born about 1564, and his death was lamented in an epigram by Fitzgeoffrey in 1601. He tells us himself that his birthplace was Lowestoft. It would seem from a passage in one of his pamphlets that he travelled in Italy after leaving Cambridge, and then he followed the example of Greene and Marlowe, his fellow Cantabs, in trying to make a living by literature in London. Nash was really a journalist born out of due time; he frequently boasts of his power of writing "as fast as his hand can trot"; his style was brilliant and picturesque; he had a keen sense of the ridiculous, was quick in argument, and not without abundance of miscellaneous learning. In the circumstances, there being no market for his gifts, he fared like the other university wits who made the same premature venture at the time to "distil ink into gold," struggled brilliantly for some years, and succumbed. It was as a "notable railer" both against individuals and against the vices and the absurdities of the time, as a man than whom none "used better or more bitter gall in ink," that Nash made his reputation. His first effort was a preface to Greene's *Menaphon*, in 1587. In this he made boisterous ridicule, with the arrogance of youth and high spirits, of current literature, laughing especially at the bombast of Marlowe's *Tamburlaine*, and promised to follow up his attack with an ...

of he le, es- *in* ly. 11. ed us he to ges ces e." rce rth his hat try ing *nt.* *ver*

Jerusalem, a really eloquent composition. In the preface to this, "not basely fear-blasted, or constraintively overruled, but purely pacificatory," he holds out the hand of friendship to Gabriel Harvey, with whom he had begun a match in personal abuse, recorded in D'Israeli's *Quarrels of Authors*. The overture was not accepted, and Nash resumed his "humorous objurgation" of the enemy. After Marlowe's death he put the unfinished tragedy of *Dido* in shape for the stage, but he had no portion of Marlowe's genius. In 1597 he was in trouble with the authorities for a play called the *Isle of Dogs*, which has not been preserved. The author retired to Yarmouth, and there wrote his last work *Lenten Stuff* (1599), nominally "in praise of a red herring," but really a description of Yarmouth which would now make the fortune of a special correspondent.

NASHUA, a city of the United States, in Hillsborough county, New Hampshire, on hilly ground at the confluence of the Merrimac and the Nashua, 40 miles north-north-west of Boston by the Boston, Lowell, and Nashua Railroads. In 1803 the site was "a sandy plain covered with pine trees"; but after the formation of the Nashua Manufacturing Company in 1823 the village rapidly grew up, and by 1853 it was incorporated as a city. Its population increased from 10,543 in 1870 to 13,397 in 1880. The water-power of the Nashua river being rendered easily available by means of a canal 3 miles long and 8 feet deep, constructed in 1825–26, a great variety of industrial establishments are situated in the city. Besides the sheetings, shirtings, prints, and flannels manufactured by the original Nashua company and its younger rivals, iron goods, locks, edge tools, bedsteads, carpets, shuttles, bobbins, shoes, cards, glazed paper, are all produced on a large scale.

NASHVILLE, a city of the United States, capital and largest city of Tennessee, and seat of justice of Davidson county, stands on the Cumberland River (spanned there by a suspension bridge and a truss railway bridge with a "draw" 200 feet long), 200 miles above its junction with the Ohio, in 36° 10′ N. lat. and 86° 49′ W. long. Occupying a site of considerable irregularity, and dominated by the hill (558 feet above the sea) on which the capitol is built, Nashville on the whole presents a picturesque and attractive appearance. The capitol is an imposing stone edifice, erected in 1845 at a cost of nearly $1,000,000, and surmounted by a central tower 206 feet in height. Other public buildings deserving mention are the court-house (1857), the market-house and city-hall (1855), the State penitentiary (1830), the State blind asylum (1850), the four universities, and two large female seminaries. Nashville University, incorporated as Davidson College in 1785, as Cumberland College in 1806, and under its present name in 1825, now embraces three distinct schools,—Montgomery Bell Academy, Nashville Medical College, one of the largest in the Southern States, and the Normal College, established and endowed by the trustees of the Peabody Fund. Vanderbilt University was founded in 1872 by six conferences of the Methodist Episcopal Church, South, and in 1873 was named after Cornelius Vanderbilt of New York, who gave it $1,000,000. His son has given it about $250,000 additional. It has a fine group of buildings and 75 acres of land west of the city. In 1882 it had 51 instructors and 603 students. Fisk University, established in 1866 for the education of men of colour, and widely known through the Jubilee Singers, had 18 teachers and 424 students in 1882. The Tennessee Central (Methodist) College, likewise dating from 1866, is intended for coloured students, as is also the Roger Williams University (Baptist). The State library in the capitol had 27,000 volumes in 1882; and the Watkins

Institute library occupies a building erected in 1882 at a cost of $130,000. Being the natural centre of a wide productive region, and well served by river and rail, Nashville has an extensive and rapidly growing trade, especially in cotton and tobacco. Its manufacturing establishments comprise three large cotton factories (34,000 spindles, 700 hands in 1882), saw-mills, grist-mills, planing factories, carriage factories, extensive furniture factories, distilleries, paper-mills, cotton-seed-oil mills, and stove foundries. The population was 5566 in 1830, 10,165 in 1850, 16,988 in 1860, 25,865 in 1870, and 43,350 in 1880.

Settled in 1780, Nashville received incorporation as a town in 1784 and as a city in 1806. It was not till 1843 that it became the capital of the State, though, with the exception of the period from 1815 to 1826, the legislature had met there from 1812. In February 1862 Nashville was evacuated by the Confederate General A. S. Johnston, and was held from that time by the Federal forces. The attempt made in December 1864 by the Confederate General Hood to recover the now strongly-fortified town resulted in the "battle of Nashville," in which his army was completely routed by that of General G. H. Thomas.

NÁSIK, or NASSICK, a district in the Bombay presidency, India, between 19° 34′ and 20° 52′ N. lat., and between 73° 21′ and 75° 2′ E. long., bounded on the N. by Khándesh, E. by the Nizám's Dominions, S. by Ahmednagar, and W. by Thána (Tanna), with an area of 5940 square miles. With the exception of a few villages in the west, the whole district is situated on a table-land from 1300 to 2000 feet above sea-level. The western portion is hilly, and intersected by ravines, and only the simplest kind of cultivation is possible. The eastern tract is open, fertile, and well cultivated. The Sahyádri range stretches from north to south; the watershed is formed by the Chánder range, which runs east and west. All the streams to the south of that range are tributaries of the Godávari. To the north of the watershed, the Gírna and its tributary the Mosam flow through fertile valleys into the Tápti. The district generally is destitute of trees, and the forests which formerly clothed the Sahyádri hills have nearly disappeared; efforts are now being made to prevent further destruction, and to reclothe some of the slopes. The district contains several old hill forts, the scenes of many engagements during the Mahratta wars. Násik district became British territory in 1818 on the overthrow of the peshwá. The population in 1881 was 781,206 (Hindus 683,579, Mohammedans 35,294).

NÁSIK, the chief town of the district (population 22,436), is situated on the Godávari, and is considered a place of great sanctity by Hindus, who make pilgrimages to its temples from all parts of India. Places of worship fringe both banks of the river, and even the bed of the stream is thickly dotted with temples and shrines. Násik has brass and copper works, but commercially is of little more than local importance.

NASIR KHOSRAU. Abú Mu'ín-ed-din Násir b. Khosrau, the first great didactic poet of Persia, was a descendant of the imám 'Alí Ridá, and was born, according to his own statement in one of his kasídas, 394 A.H. (1004 A.D.), at Kubádiyán, near Balkh in Khorásán. The first forty-two years of his life are obscure; we learn from incidental remarks of his that he was a Sunnite, probably according to the Ḥanafite rite, well versed in all the branches of natural science, in medicine, mathematics, astronomy, and astrology, in Greek philosophy, and the interpretation of the Koran; that he had a comprehensive knowledge of many other philosophic systems and religious creeds professed in the East; and that he was, withal, much addicted to worldly pleasures, especially to excessive wine drinking, the renunciation of which forms a prominent topic in his later odes. He had studied Arabic, Turkish, Greek, the vernacular languages of India and Sind, and perhaps even Hebrew; he had visited Multán and Lahore, and been—probably in an official capacity—an eye-witness of the splendid Ghaznavide court under Sultán Mahmúd, Firdousí's patron, and his son Mas'úd. Later on he had chosen Merv for his residence, and was the owner of a house and garden there. When he first steps into the full light of history, in 437 A.H. (1045 A.D.), we see him in the position of a financial secretary and revenue collector of the Seljúk sultan Toghrulbeg, or rather of his brother Jághirbeg, the emír of Khorásán, who had conquered Merv in 1037. The introductory passages of the *Safarnáma*, together with a number of verses in the above-mentioned kasída, which belongs to the same period, clearly manifest the peculiar state of mind in which Násir was at that time. Like Faust he had fathomed the depth of all human knowledge, like him he had passed through the whirlpool of passions and sensual pleasures, he had tried to drown his doubts and troubles in the wine cup, and yet he had only grown more and more dissatisfied with himself; nothing could quench his ever-increasing thirst for a higher intelligence, for a more profound comprehension of the Godhead, and the manifestations of the divine power in the universe. He had evidently reached the turning-point of his life, and, inspired by a heavenly voice (which he pretends to have heard in a dream), he abjured all the luxuries of life, and resolved upon a pilgrimage to the holy shrines of Mecca and Medina, hoping to find there the solution of all enigmas, and to return a thoroughly reformed man. The graphic description of this journey is contained in the *Safarnáma*, a book that, quite apart from the personal interest we feel in the author, ranks high among the memoirs of travel as giving us the most authentic account of the state of the Mussulman world and the condition of Persia, Arabia, Syria, Palestine, and Egypt in the middle of the 11th century. The minute sketches of Jerusalem and its environs, moreover, are of the highest practical value, even at the present day, for our explorations in the Holy Land. During the seven years of his journey (1045–52 A.D.) Násir visited Mecca four times, and performed all the rites and observances of a zealous pilgrim; but the fascinating influence of the Holy City upon his mind was greatly outweighed by that of Cairo, the capital of Egypt, and the residence of the Fátimite sultan Mostanṣir billáh, the great champion of the Shí'a, and the spiritual as well as political head of the house of 'Alí, which was just then waging a deadly war against the 'Abbáside caliph of Baghdád, and the great defender of the Sunnite creed, Toghrulbeg the Seljúk. At the very time of Násir's visit to Cairo, the power of the Egyptian Fátimites was in its zenith; Syria, the Hijáz, Africa, and Sicily obeyed Mostanṣir's sway, and the utmost order, security, and prosperity reigned in Egypt. Cairo appeared as an earthly paradise in Násir's eyes; he became, as his poems clearly indicate, thoroughly imbued there with Shí'a doctrines, and their successful introduction into his native country was henceforth the sole aim and object of his life. The hostilities he encountered in the propagation of these new religious ideas after his return to Khorásán in 1052 and Sunnite fanaticism compelled him at last to flee, and after many wanderings he found a refuge in Yumgán, in the mountains of Badakhshán, where he spent as a hermit the last decades of his life, and gathered round him a considerable number of devoted adherents, who have handed down his doctrines to many following generations. The Dábistán (translated by Shea and Troyer, Paris, 1843, vol. ii. p. 419 *sq.*) fixes his flight from Khorásán in 456 A.H. (1064 A.D.), but there is strong evidence in some of his kasídas that this event took place some four or five years before that date; and as his death occurred in 481 A.H. (1088 A.D.) he must have lived in his exile from

twenty-five to thirty years. His "nom de plume" was "Hujjat."

Most of Násir's lyrical poems were composed in his retirement, and their chief topics are—an enthusiastic praise of 'Ali, his descendants, and Mostansir in particular; passionate outcries against Khorásán and its rulers, who had driven him from house and home; the highest satisfaction with the quiet solitude of Yumgán; and utter despondency again in seeing himself despised by his former associates, and for ever excluded from participation in the glorious contest of life. But scattered through all these alternate outbursts of hope and despair we find precious lessons of purest morality, and solemn warnings against the tricks and perfidy of the world, the vanity of all earthly splendour and greatness, the folly and injustice of men, and the hypocrisy, frivolity, and viciousness of fashionable society and princely courts in particular. It is the same strain which runs, although in a somewhat lower key, through his two larger mathnawis or double-rhymed poems, the *Rushanáináma*, or "book of enlightenment," and the *Sa'ádat-náma*, or "book of felicity." The former is divided into two sections: the first, of a metaphysical character, contains a sort of practical cosmography, chiefly based on Avicenna's theories, but frequently intermixed both with the freer speculations of the well-known philosophical brotherhood of Basra, the Ikhwán-es-safá,[1] and purely Shí'itic or Isma'ílitic ideas; the second, or ethical section of the poem, abounds in moral maxims and ingenious thoughts on man's good and bad qualities, on the necessity of shunning the company of fools and double-faced friends, on the deceptive allurements of the world and the secret snares of ambitious craving for rank and wealth. It concludes with an imaginary vision of a beautiful world of spirits who have stripped off the fetters of earthly cares and sorrows and revel in the pure light of divine wisdom and love. If we compare this with a similar allegory in Násir's díwán, which culminates in the praise of Mostansir, we are fairly entitled to look upon it as a covert allusion to the eminent men who revealed to the poet in Cairo the secrets of the Isma'ílitic faith, and showed him what he considered the "heavenly ladder" to superior knowledge and spiritual bliss. The passage, thus interpreted, lends additional weight to the correctness of Dr Ethé's reconstruction of the date of the *Rushanáináma*, viz., 440 A.H. (1049 A.D.), which, notwithstanding M. Schefer's objections, is warranted both by the astronomical details and by the metrical requirements of the respective verses. That of course does not exclude the possibility of the bulk of the poem having been composed at an earlier period; it only ascribes its completion or perhaps final revision to Násir's sojourn in Egypt.

A similar series of excellent teachings on practical wisdom and the blessings of a virtuous life, only of a severer and more uncompromising character, is contained in the *Sa'ádatnáma*; and, judging from the extreme bitterness of tone manifested in the "reproaches of kings and emirs," we should be inclined to consider it a protest against the vile aspersions poured out upon Násir's moral and religious attitude during those persecutions which drove him at last to Yumgán. Of all the other works of our author mentioned by Oriental writers there has as yet been found only one, the Zád-elmusáfirín (in the private possession of M. Schefer, Paris); and we can very well dismiss the rest as being probably just as apocryphal as Násir's famous autobiography (found in several Persian tadhkiras or biographies of poets), a mere forgery of the most extravagant description, which is mainly responsible for the confusion in names and dates in older accounts of our author.

See Sprenger's *Catalogue of the Libraries of the King of Oudh*, 1854; H. Ethé, "Násir Chusrau's *Rushanáináma*," in *Z. D. M. G.*, xxxiii., xxxiv., 1879-80; E. Fagnan, "Le livre de la félicité," in vol. xxxiv. of the same journal, 643-674; Ch. Schefer, *Sefer Nameh, publié, traduit, et annoté*, Paris, 1881; H. Ethé, in *Göttinger Nachrichten*, 1882, pp. 124-152, and *Z. D. M. G.*, 1882, pp. 478-508. Fagnan in *Journ. As.*, 7th ser., vol. xiii. p. 164 *sq.*, and Rieu, *Cat. Pers. MSS. in Br. Mus.*, concluded that the poet and the pilgrim were different persons. The opposite view was developed by Ethé. (H. E.)

NASMYTH, ALEXANDER (1758–1840), portrait and landscape painter, was born in Edinburgh on September 9, 1758. He studied at the Trustees' Academy under Runciman, and, having been apprenticed as an heraldic painter to a coachbuilder, he, at the age of sixteen, attracted the attention of Allan Ramsay, who took the youth with him to London, and employed him upon the subordinate portions of his works. Nasmyth returned to Edinburgh in 1778, and was soon largely patronized as a portrait painter. He also assisted Mr Miller of Dalswinton, as draughtsman, in his mechanical researches and experiments; and, this gentleman having generously offered the painter a loan to enable him to pursue his studies abroad, he left in 1782 for Italy, where he remained two years. On his return he painted the excellent portrait of Burns, now in the Scottish National Gallery, so well known through Walker's engraving. Political feeling at that time ran high in Edinburgh, and Nasmyth's pronounced Liberal opinions, which he was too outspoken and sincere to disguise, gave offence to many of his aristocratic patrons, and led to the diminution of his practice as a portraitist. In his later years, accordingly, he devoted himself mainly to landscape work, and did not disdain on occasion to set his hand to scene-painting for the theatres. He has been styled, not unjustly, the "father of Scottish landscape art." His subjects are carefully finished and coloured, but are wanting in boldness and freedom. Nasmyth was also largely employed by noblemen throughout the country in the improving and beautifying of their estates, in which his fine taste rendered him especially skilful; and he was known as an architect, having designed the Dean Bridge, Edinburgh, and the graceful circular temple covering St Bernard's Well, which stands near it. Nasmyth died in his native city on 10th April 1840. His youngest son, James, is the well-known inventor of the steam-hammer. His six daughters all attained a certain local reputation as artists, but it was in his eldest son, Patrick, that the artistic skill of his family was most powerfully developed. For an interesting account of the Nasmyth family see James Nasmyth's *Autobiography*, 1883.

NASMYTH, PATRICK (1787–1831), the eldest son of Alexander Nasmyth, was born at Edinburgh on January 7, 1787. Having studied under his father, he went to London at the age of twenty, and soon attracted attention as a clever landscapist. He was a diligent student of the works of Claude and Richard Wilson, and of Ruysdael and Hobbema, upon whom his own practice was mainly founded. His most characteristic paintings are of English domestic scenery, full of quiet tone and colour, and detailed and minute expression of foliage, and with considerable brilliancy of sky effect. They were executed with his left hand, his right having in early life been injured by an accident. He died at Lambeth, August 17, 1831, during a thunderstorm, which at his own request he had been raised in bed to contemplate.

NASSAU, now forming the bulk of the government district of Wiesbaden, in the Prussian province of Hesse-Nassau, was till 1866 an independent and sovereign duchy of Germany, consisting of a compact mass of territory, 1830 square miles in area, bounded on the S. and W. by the Main and Rhine, on the N. by Westphalia, and on the E. by Hesse. This territory is divided into two nearly equal parts by the river Lahn, which flows from east to west into the Rhine. The southern half is almost entirely occupied by the Taunus Mountains, which attain a height of 2900 feet in the Great Feldberg, while to the north of the Lahn is the barren Westerwald, culminating in the Salzburgerkopf (2000 feet). The valleys and low-lying districts, especially the Rheingau, are very fertile, producing abundance of grain, flax, hemp, and fruit; but by far the most valuable product of the soil is its wine, which includes several of the choicest Rhenish varieties (Johannisberger, Marcobrunner, Assmannshauser, &c.). Nassau is one of the most thickly wooded regions in Germany, about 42 per cent. of its surface being occupied by forests, which yield good timber and harbour large quantities of game. The rivers abound in fish,—the salmon fisheries on the Rhine being especially important. There are upwards of a hundred mineral springs in the district, most of which formerly belonged to the duke, and afforded him a considerable part of his revenue. The best-known are those of Wiesbaden, Ems, Soden, Schwalbach, Schlangenbad, Geilnau, and Fachingen. The other mineral wealth of Nassau includes iron, lead, copper, building

[1] Compare the *Journal of the Asiatic Society of Bengal*, 1848, vol. xvii., part 1, p. 501 *sq.*, and part 2, p. 183 *sq.*

stone, coals, slate, a little silver, and a bed of malachite. Its manufactures, including cotton and woollen goods, are unimportant, but a brisk trade is carried on by rail and river in wine, timber, grain, and fruit. There are few places of importance besides the above-named spas; Höchst is the only manufacturing town. Wiesbaden, with 50,238 inhabitants, is the capital of the government district as it was of the duchy. In 1864 the duchy contained 468,311 inhabitants, of whom 242,000 were Protestants (including the reigning house), 215,000 Roman-Catholics, and 7000 Jews. The ecclesiastical jurisdiction was in the hands of the Protestant bishop of Wiesbaden and the Roman Catholic bishop of Limburg. Education was amply provided for in numerous higher and lower schools. The annual revenue of the dukedom was about 4,000,000 guldens (£400,000). It furnished a contingent of 6000 men to the army of the German Confederation.

During the Roman period the district enclosed by the Lahn, the Main, and the Rhine was at first occupied by the Mattiaci and then by the Alemanni. The latter were subdued by the Franks under Clovis in 496, and at the partition of Verdun in 843 the country became part of the Eastern or German empire. Christianity seems to have been introduced in the 4th century. The founder of the house of Nassau is usually recognized in Count Otho of Laurenburg, brother of King Conrad I., who flourished on the banks of the Lahn in the 10th century. His successors afterwards took the title of counts of Nassau, from a castle which they erected on a steep hill overlooking the Lahn, and in 1192 transferred their allegiance from the archbishop of Treves to the emperor of Germany. In 1255 Walram and Otho, the two sons of Count Henry the Rich, divided between them their paternal inheritance, which had in the meantime been steadily increasing, and founded the two Nassovian dynasties which have flourished down to our own times.

The fortunes of the Othonian or younger branch have been the more brilliant, but belong properly to the history of Holland. In 1564 Count William of Nassau, the hero of the Dutch war of independence, succeeded to the principality of Orange, which furnished the historical title of himself and his descendants. The house is now represented by the king of the Netherlands.

Adolf of Nassau, the son of the founder of the elder or Walram line, and progenitor of the dukes of Nassau, became emperor of Germany in 1292, but was defeated and slain in 1298 by his rival Albert of Austria. In 1366 the head of the house was created a prince of the empire, and the Reformation was introduced in the second half of the 16th century. The territories of the house of Walram were frequently partitioned among various branch lines, few of which perpetuated themselves beyond a few generations. At the beginning of the 19th century we find two lines still flourishing—Nassau-Ufingen and Nassau-Weilburg. Both these joined the Rhenish Confederation in 1806, and the prince of Nassau-Ufingen, as head of his family, received the ducal title from the hands of Napoleon. After the battle of Leipsic both princes threw in their lot with the allies. In 1816 the duke of Nassau-Ufingen died, and the prince of Weilburg succeeded to the whole of the Nassovian territory, with the title of duke of Nassau.

This prince had already, in 1814, granted his subjects a limited constitution, providing for two representative chambers on a landed-property basis, and this came into force in 1818. The estates, however, came almost at once into collision with the duke on the question of the ducal domains, and the dissensions arising from this source were not compromised till 1834. In 1835 the duchy took an important step in the development of its material prosperity by joining the Zollverein. In 1848 Duke Adolf was compelled to yield to the temper of the times and grant a more liberal constitution, with a single chamber elected by universal suffrage; but the following years witnessed a series of reactionary measures which reduced matters to their former unsatisfactory condition. The duke adhered steadfastly to his Conservative principles, while his people showed their sympathies by returning one Liberal chamber after another. In 1866, though the chambers refused a vote of credit for military purposes, the duke espoused the cause of Austria, and in doing so sealed the fate of his duchy. A little later he was a fugitive before the Prussian troops, and on October 3d, 1866, Nassau was formally incorporated with the kingdom of Prussia.

The little town of Nassau, on the right bank of the Lahn, 15 miles above Coblenz, is interesting as the birthplace of the celebrated Prussian statesman, Baron Stein. Adjacent are Burg Stein, his ancestral seat, and Burg Nassau, the cradle of the Nassovian dukes. Nassau is said to have existed as early as the 8th century under the name of Nasonga. Population (1880) 1786.

See Schliephake, *Geschichte von Nassau*, 1866–76, Arnoldi, *Geschichte von Nassau-Oranien*; the *Annals* of the "Verein fur Nassauische Alterthumskunde und Geschichtsforschung"; Daniel, *Handbuch der Geographie*, 5th ed., 1881.

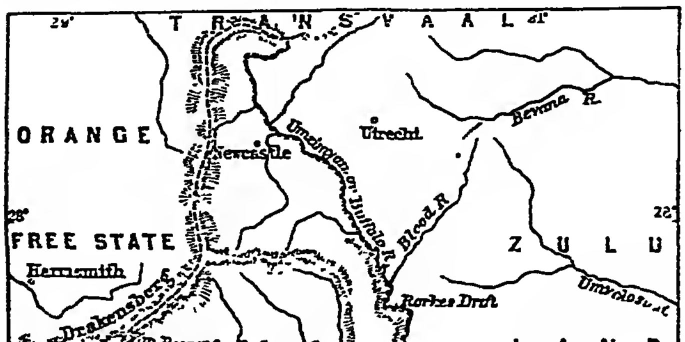
NASSAU, the capital of New Providence, and seat of government of the Bahama Islands, 25° 5′ 36″ N. lat., 77° 21′ 15″ W. long. At one time the town was noted as a great rendezvous for pirates. Its harbour, admitting vessels drawing 12 feet, acquired much importance during the blockade of the southern ports in the American War. The population of Nassau, principally negroes and coloured people, is about 8000, out of the total island population of 11,653. Nassau extends for 3¼ miles along the north shore. It is a very pretty town, celebrated for its healthy climate, and resorted to for sea-bathing by visitors from America. It has a Government house, a plain stone cathedral, and several churches and chapels, and is a military station and a bishop's see. Numbers of the inhabitants support themselves by looking after wrecks. Preserved fruit in tins is exported, also woods, fruit, sponges, salt, &c.

NASTURTIUM. The common water-cress (*N. officinale*), so largely used as a salad, may be taken as a representative of this genus of *Cruciferæ*,—a genus characterized, for the most part, by pinnately divided foliage, white or yellow cruciform flowers, and long pods with a double row of seeds. The embryo root is folded up along the edges of the cotyledons, accumbent. Four species are British, but the only one cultivated is the *N. officinale*. Its flavour is due to an essential oil containing sulphur, its antiscorbutic properties to the presence of iodine, iron, and phosphates. Although now so largely consumed, it does not appear to have been cultivated in England prior to the present century, though in Germany, especially near Erfurt, it had been grown long previously. The plants are grown in shallow water in rows parallel to the direction of the current, and from 5 to 7 feet apart. It is essential that the water be free from impurity, especially sewage. To avoid this latter contingency cresses are sometimes grown in a north border, the soil being kept constantly moist; or they may be grown in pots in a frame or greenhouse, the pots being placed in a saucer of water, and the plants frequently watered. This plan was introduced by Mr Shirley Hibberd, and when the requisite attention is given is highly successful when commercial considerations are not a matter of primary importance. The name *Nasturtium* is also applied in gardens, but incorrectly, to the species of *Tropæolum*.

NATAL, a British colony on the south-east coast of Africa, situated nearly between 29° and 31° S. lat. and 29° and 32° E. long., is bounded on the N.E. by Zululand and the Transvaal, on the S.E. by the Indian Ocean, on the N.W. by the Orange Free State and the Transvaal, and on the S.W. by Basutoland, Griqualand East, and the country of the Pondas. It is of an irregular diamond shape, with a length of about 270 miles from north to south, and a breadth of 170 miles from east to west. The extent of sea-coast is about 150 miles, and its area is about 17,000 square miles, or 11,000,000 acres (one-third of the size of England).

For several miles northward from the Bluff at Durban the coast is low, but well wooded, and broken in several places by the mouths of rivers and streams; to the south of the Bluff it is of moderate elevation near the sea, the hills rising inland to a considerable height. Rich in verdure, and in the wet season clothed with bright green grass and clumps of trees and bushes, and diversified by numerous streams, the landscape indicates a country of great fertility of soil. From the coast to the western boundary of the colony the land rises by terraces or plateaus to an elevation of at least 4000 feet above the sea-level. For about 15 miles inland it is broken and hilly, and thickly covered with long grass, and in some parts studded with jungly bush and clumps of palm,

enphorbia, and mimosa. For some 30 miles farther inland the more elevated but less broken land loses all tropical character, and presents large tracts of good pasturage, but with scarcely any bnsh or wood. Beyond this district, at an ever-increasing elevation, the country, still hilly and undulating, opens out in many places into more extensive grass plains, generally denuded of bush or wood, although in some localities and in the "kloofs" with a south-eastern aspect are dense clumps of forest trees netted over in many instances with ferns; the western boundary of these rising lands is the Drakensberg mountain-range, which has an altitude of some 3000 or 4000 feet above the country at its base, and an absolute maximum altitude of 10,350 feet above sea-level. Apart from the Drakensberg range, the country, though hilly and much broken, has no monntains of note; many large hills, however, with flattened tops (table mountains) stand out singularly high



Map of Natal.

above the surrounding country, presenting a peculiar appearance to one unaccustomed to South-African scenery.

The colony is well watered throughout, but none of the streams are navigable, and all have bars at their entrances; attempts are being made to form harbours at the mouths of the Umkomanzi and the Umzimkulu to the south of Durban. The Umgeni, about 12 miles from Pietermaritzburg, has a sheer fall of about 360 feet, and when it is flooded the rush of its waters is a magnificent spectacle. The harbour or port of Natal at Durban (strictly D'Urban), the only natural one in the colony, consists of an outer bay or roadstead, which has a fair anchorage, and an inner bay; at the entrance of the latter is a deepwater channel, where ships of large tonnage can be safely moored, but a sand bar at its entrance restricts the passage of large ships to the highest tides, and in rough weather renders communication with the outer bay quite impracticable. This bar varies constantly throughout the year, and probably is influenced by the Agulhas stream and other oceanic currents. Much money has been spent on works for the removal of the bar, without any good result, but other plans are now being adopted, with every hope of success. When this obstacle is removed Natal will possess one of the best harbours on the south-east coast of Africa.

Climate.—The summer or hot rainy season lasts from October to March inclusive, and the six remaining months form the winter or cold dry season. The following are the average temperatures for the three hottest and three coldest months of the year, taken from observations at Durban, Pietermaritzburg, and Byrne extending over ten years:—

	Highest.	Lowest.	Mean.
December, January, and February.....	97·5	53·3	71·2
June, July, and August	83·4	31·9	56·7

In the summer months cloudy afternoons with thunderstorms are frequent, and the accompanying rains are very cool and refreshing. Within 30 miles of the coast fires in dwellings are seldom required throughout the coldest months of the year. The rainfall averages 33·50 inches; it is heaviest in the summer months, but in June and July it frequently happens that there is no rain at all over a large portion of the colony. From July to December the upper districts are occasionally subject to hot winds, during which all vegetation droops as if dying, and languor and depression affect all animal life; but these seldom reach to within 20 miles of the coast. Violent hailstorms are not frequent, but hailstones have occasionally killed fowls, dogs, and goats, and in some instances have cut through iron roofing.

Geology.—Along the coast belt there are evidences of comparatively recent upheaval. The high land of the colony rests on granite, trap, and sandstone, the last of the Old Silurian type. Sandstone of a more recent epoch, well suited for building purposes, is sometimes met with. As a rule these fundamental rocks are found under thick beds of shale, the surface being of the most varied description, and never of the same quality over any very extensive area. The soil on the coast is mostly sandy loam, except where the valleys have alluvial deposits from disintegrated shales and erupted rocks. In the uplands the deep light, heavy black, and fine red loams are distributed over beds of clay, ironstone, or granite in areas of varying extent. Ironstone is to be met with in great quantities. Coal of several qualities exists in the Klip River county, with seams varying from 4 to 10 feet in thickness; analysis and experiment have shown it to be very suitable for locomotive and general steam purposes. Some descriptions of it are well suited for gas, and nearly all of it will make good household coal. The area of the available coal-field is some 1350 square miles, and at a moderate computation the mines contain 2,000,000,000 tons of serviceable coal. In association with these seams of coal very valuable iron ore has been discovered. Vast deposits of fine white and yellow crystalline marbles have recently been found about 6 miles inland from the mouth of the Umzimkulu river. Slight indications of copper have been met with. In the extreme north are some mineral springs which have a temperature of about 130° Fahr., and are considered to possess medicinal qualities.

Flora.—The chief forms of plants peculiar to Natal are the liane and mimosa along the coast, and the orchid, aloe, pothos, liliaceous, and fern forms in the upland districts. The heaths and proteads common at the Cape of Good Hope are seldom if ever found in Natal, but almost any varieties of the flora of semi-tropical and temperate countries that are introduced attain perfection. The indigenous timber trees, mostly found in isolated clumps and in somewhat inaccessible situations, are principally the yellow wood (*Podocarpus elongatus*), sneezewood (*Pteroxylon utile*), stinkwood (*Oreodaphne*

bullata), black ironwood (*Olea laurifolia*), white ironwood (*Vepris lanceolata*), and the mangrove (*Rhizophora*); all are very useful woods, and the yellow wood, sneezewood, stinkwood, and ironwood when polished have grain and colour equal to maple, walnut, and ebony. The "rooibesje," red pear, and milkwood trees are used for boatbuilding. The Australian *Eucalyptus* and *Casuarina* in great variety, and many other imported trees, including syringas, wattles, acacias, willows, pines, cypress, cork, and oak all thrive when properly planted and protected from grass fires.

Fauna.—The herds of elephants which roamed in the coast bushes in 1837 have disappeared, and the roar of the lion is no longer to be heard in the uplands. The hippopotamus is very scarce, and nearly all, if not all, the buffalo and quagga have crossed over into Zululand. Leopards or tigers and tiger cats (all called by the natives "ingwe"), and hyænas and wild dogs (*Canis pictus*) of different species, are still found in or about bush jungles and forest clumps; elands (*Antilope oreas*) are preserved on some estates, and there are at least ten distinct species of antelope. Ant-eaters (*Orycteropus capensis*), porcupines, rock rabbits, hares, and cane rats are common in different localities. Baboons (*Cynocephalus porcarius*) and monkeys of different kinds frequent the mountains and rocky kloofs and bush and timber lands. The birds of Natal are of many species; some have beautiful plumage, but none of them, with the exception of the canary, are to be considered as songsters. The crocodile is to be found at the mouths of all rivers, and for a certain distance inland from the sea. Of snakes there are about forty distinct species or varieties. The most dreaded by the natives are called "imamba," of which there are at least eight different kinds; these snakes elevate and throw themselves forward, and have been known to pursue a horseman. One sort of imamba, named by the natives "indhlondhlo," is crested, and its body is of a bright flame colour. The sluggish puff-adder (*Clotho arietans*) is common and very dangerous. A hooded snake (*Naja hæmachates*), the "*imfezi*" of the natives, is dangerous, and spits or ejects its poison; and besides this there are a few other varieties of the cobra species. The largest of the serpent tribe, however, is the python (*Hortulia natalensis*), called "inhlwati" by the natives: its usual haunts are by streams amongst rocky boulders and in jungles, and instances are recorded of its strangling and crushing adult natives. Insects abound in great numbers, the most troublesome and destructive being the tick (*Ixodes natalensis*), which infests the pasturage, and the white ant (*Termes mordax*). Occasionally vast armies of caterpillars make a sudden appearance and advance over large tracts of country, devouring all vegetation in their line of march. The fish moth, a steel-grey slimy active fish-shaped insect, is found in every house, and is very destructive in the wardrobe and library. Fish of excellent quality and in great quantities abound on the coast. Prawns, crayfish, and oysters are also obtainable, and turtle (*Chelonia mydas*) are frequently captured. Little attention, however, has been given to deep-sea fishing, and the only fishermen are the coolies, who use nets along the beach. The natives (Zulus) as a rule will not touch fish. Freshwater scale-fish are mostly full of bones, but fine eels and barbel are plentiful in the rivers.

Agriculture.—The chief crop is maize, known in South Africa as "mealies," its grain constituting the principal food of about seven-eighths of the population. Maize, indeed, and Kaffre corn (*Sorghum Caffrorum*), with pumpkins and sweet potatoes (*Convolvulus Batatas*), "imphee" or "imfi" (*Sorghum saccharatum*), and tobacco are about the only crops raised by the natives. The European farmers in the uplands, by irrigating the land in the winter months, produce wheat of very fair quality, but not in sufficient quantity to supply the demands of the colony. Oats, barley, and other grains grow readily; and nearly all European vegetables yield fair crops in suitable localities. Arrowroot succeeds well on the coast, and is an article of export. Some years ago coffee and cotton had the attention of the planter, but both are now neglected. Rice has been cultivated by some farmers, but not to any great extent. Tobacco flourishes luxuriantly wherever there is good soil, but the difficulties in the way of curing and manufacturing it prevent its being at present an article of export. The cultivation and manufacture of sugar have attracted most attention of late; sugar, indeed, with its products is the principal staple produced in and exported from Natal. The capsicum for cayenne pepper, and ground-nuts (*Arachis hypogæa*) for oil, are also grown for exportation. Tea has been cultivated of late by some few planters on the coast, and promises ere long to be grown on a much larger scale. There are but few indigenous fruits, the principal being the Natal orange (a species of *Strychnos*), the Natal plum or "amatungula" (*Arduinia grandiflora*), the Kei apple (*Aberia caffra*), Cape gooseberry (*Physalis pubescens*), and the Kaffre fig, the fruit of the *Urostigma natalensis*. Many subtropical fruits, however, and fruits of European culture thrive well in Natal.

Stock.—Previous to 1855 large and numerous herds of cattle pastured over the whole country, but in that year "lung-sickness," an epidemic of the nature of pleuro-pneumonia, broke out with great virulence, and scarcely 4 per cent. of the animals attacked recovered. Lung-sickness and "red water" still claim many victims annually, and are the constant dread of the stock farmer. "Horse sickness," a form of anthrax, is very fatal to horses, especially in wet summers. The following figures give approximately the number of the several kinds of stock belonging to Europeans and natives respectively in 1880:—

Stock.	Europeans.	Natives.
Horned cattle	140,716	379,563
Horses	17,251	15,915
Mules and donkeys	1,121	*nil.*
Angora goats	70,599	*nil.*
Other goats	6,159	166,477
Pigs	10,609	5,554
Sheep (wool-bearing)	410,353	600
Sheep (not wool-bearing)	1,931	24,509

The cattle consist principally of the Zulu, Africander, and Fatherland breeds, but recently some English shorthorns and other improved stock have been introduced. Ostriches also are farmed for the sake of their feathers, but as yet this industry has not succeeded so well in Natal as in the Cape Colony.

Commerce.—The staple productions of Natal have increased with the introduction of the sugar-cane, and sugar and rum are the principal articles of native produce exported. Wool, arrowroot, and feathers are also the outcome of local industry, but the exports of greatest value and importance are the wool and hides of the Transvaal and the Orange Free State, and feathers, ivory, and skins from the interior, which are shipped at Durban. The value of Natal sugar produced in 1856 was stated at £483, and in 1881 at £172,237. The principal imports in 1882 (total value £2,213,538) were clothing, cotton and woollen goods, haberdashery, leather manufactures, iron and ironmongery, spirits, oilman's stores, and flour, and the chief exports (£731,809) were wool, sugar, hides, ostrich feathers, and Angora hair,—by far the greater part of the imports (£1,784,345) and exports (£595,744) being received from and shipped for the United Kingdom.

Revenue and Expenditure.—The increase in the revenue and expenditure in thirty years is shown as follows:—

Year.	Revenue.	Expenditure.
1852	£37,158	£24,976
1862	93,036	85,885
1872	150,495	172,978
1882	496,783	489,113

The revenue is principally derived from customs duties, native hut taxes, transfer dues on land sales, and excise. The public debt of the colony on the 31st December 1882 was £2,101,500, with a sinking fund towards its redemption of £153,597.

Roads and Telegraphs.—Until very recently all goods and produce were conveyed in ox-waggons carrying from 3 to 5 tons weight. These had to travel on roads sometimes little better than tracks worn by traffic, and frequently impassable during wet weather; and for some years before the breaking out of the Zulu War (1879) the average cost of carriage was as high as eighteenpence per ton per mile. Now, however, three lines of railway have been opened,—one of 78 miles from the port at Durban to Pietermaritzburg, another from Durban 20 miles north to Verulam through the sugar lands in that district, and a third 7 miles southward to the sugar estates by the Isipingo river. These alone have cost the colony about £1,250,000. An additional line, of 118 miles, to cost about £1,180,000, is in process of construction from Pietermaritzburg to Ladysmith, and will no doubt be at once carried on to connect with the railways of the Orange Free State. The telegraph between Natal and the Cape Colony was opened in 1878, and in the following year telegraphic communication by way of Lorenzo Marques was extended to England. Branches of telegraph are also carried direct from Natal into the Transvaal and the Orange Free State.

Government.—The colony was annexed as a district to the Cape Colony in August 1845, but in November of the same year it was made a separate government, to be administered by a lieutenant-governor under the general control of the governor of the Cape Colony. At first the lieutenant-governor and an assistant council of four chief officials formed the executive, while the legislative council consisted of the lieutenant-governor and three principal officers. In 1856 Natal became wholly independent of the Cape, and the legislative council was made to consist of sixteen members, twelve elective and four non-elective. In 1869 the lieutenant-governor was empowered to nominate two elective members of the legislative council as members of the executive council. In 1873 the number of members was increased to twenty, fifteen being elective and five non-elective, and in 1875 eight nominee members were added. The colony is now administered by a governor, the promotion from lieutenant-governor being made 28th January 1882; and by law No. 1, 1883, the legislative council consists of thirty members, twenty-three of whom are elective and seven non-elective, two of the latter holding office during the royal pleasure. The executive

council has been further increased by two nominees not officers of the Government. The qualification for voters is the possession of freehold property worth £50, the occupation of property at an annual rental of £10, or an income of £96 per annum after three years' colonial residence. All voters are legally eligible as members. Boroughs or towns having 1000 inhabitants or upwards can form themselves into corporations for the supervision of their own municipal affairs, and townships or villages under certain conditions can frame local bye-laws.

Law and Justice.—The Roman-Dutch law by special enactment prevails within the colony, in addition to which are a number of ordinances and laws enacted by the local legislature, mostly founded upon imperial statute law. The law of evidence is the same as that of the courts of England. It has not been thought practicable as yet to bring the native population under the same laws as govern the colonists of European descent; but in 1848 the natives had their own laws confirmed by letters patent, except so far as these might be repugnant to the general principles of humanity as recognized throughout the civilized world; and they were codified and reduced into writing in 1878. Crimes amongst natives, with some few exceptions, are, however, tried by the ordinary courts. Special laws also have been passed for the benefit of the coolie immigrants. The administration of justice is conducted by a supreme court, and by the courts of the resident magistrates. The three judges of the supreme court, one of whom is chief-justice, sit in Pietermaritzburg *in banco* every alternate month, and during the other months circuit courts are held at Durban and in other towns. There is a vice-admiralty court, of which the chief-justice of the supreme court is judge and commissary. In addition to these are courts for the adjudication of cases under native law with right of appeal to the native high court, which sits under its own special judge assisted by assessors if need be; and from this high court appeal can be had to a court of which the chief-justice of the colony, the secretary for native affairs, and the judge of the native high court are judges. An appeal lies from all inferior courts to the supreme court, and in suits where the subject-matter in dispute is of the value of £500 an appeal can be had from any final judgment of the supreme court to the privy council.

Education and Religion.—In 1861 there were two collegiate institutions endowed in Natal, the one for Pietermaritzburg and the other for Durban, but little more was done as regards education until the education laws came into force in 1878, when a council of education was created to administer funds voted by the legislative council for scholastic purposes and to control all matters connected with the establishment and working of the public schools of the colony. Most of the religious bodies have good schools in their several parishes or districts; and public libraries and other literary institutions are to be found not only in Pietermaritzburg and Durban but in the principal towns and villages. Natal was erected into a see in 1853, with its cathedral in Pietermaritzburg. Proceedings were taken against Bishop Colenso (who died June 20, 1883) on certain charges of heresy, and judgment given against him by the South-African bishops in 1863; and this led eventually to the formation of a separate see in the colony. On the 25th January 1869 the bishop of Maritzburg was consecrated at Cape Town; he is a suffragan of the bishop of Cape Town, and has his cathedral church also in Pietermaritzburg. The Wesleyan Church has a very strong staff of clergy and local preachers in the colony, whilst the Congregational Church, the Dutch Reformed Church, the Presbyterian Church, and the Roman Catholic Church are all represented. At the stations of the Berlin, Free Church of Scotland, American Zulu, Hanoverian, Norwegian, and Trappist missions, great efforts are made to evangelize and train the natives and coolies.

Population.—The total population is about 380,000, of whom about 30,000 are whites, 20,000 Indian coolies, and 330,000 natives, mostly descendants of early refugees from Zululand. Of the white population about one-fifth are of Dutch extraction, and are chiefly resident in the Umvoti, Weenen, Klip River, and Newcastle divisions. Most of the coolies are located on the coast lands amongst the planters, who without their assistance would find all field and manufacturing operations impossible, as the natives cannot be depended on for continuous or skilled work.

History.—The country was discovered by Vasco da Gama, who sighted the Bluff headland at the entrance to the bay forming the present port at Durban on Christmas Day in 1497, and so named the country Terra Natalis. From that date little is recorded until the survivors of the crew of the Dutch ship "Stavenisse," wrecked on the coast in 1686, gave their report of the country and its inhabitants. In 1721 the Dutch formed a settlement, but it was soon abandoned. Subsequently, about 1810, it would seem that Chaka, chief of the Amazulu, swept with his warriors through the whole of Natal and the adjoining territories, destroying all males, and making booty of the cattle and women. One tribe, the Amatuli, however, after offering resistance to the invader, retreated into the dense bush near the Bluff and were amongst the few aborigines when the British took possession of the country. In 1824 Lieutenant Farewell and about twenty companions landed in Natal with the view of colonizing it, and for that purpose entered into a treaty with Chaka. Some four years after their arrival, however, Chaka was murdered by his brother Dingaan, and the settlement was broken up. In 1835 another British officer, Captain Allen Gardner, got permission from Dingaan to introduce missionaries into the country, and at once formed the township of Durban, at the port where there were still a few English settlers. In 1837 several Dutch farmers made an exodus from the Cape Colony, and one of their leaders, Pieter Retief, with the assistance of the Rev. Mr Owen, who had been for some time a resident missionary at Dingaan's own head kraal, obtained from Dingaan a cession of the whole territory of Natal. Immediately after the conclusion of the treaty Retief and his followers were treacherously murdered, and the attempt was made to extirpate the Boers throughout the length and breadth of the land. The latter with their firearms eventually proved more than a match for their numerous assailants, and joining Mpanda, who had rebelled against his brother Dingaan, utterly routed Dingaan's army on the banks of the White Umvolozi in 1840, and drove him to the Amaswazi country, where he was shortly after assassinated. Natal became a British colony on 8th August 1843, and, owing no doubt to the fame of the security and protection to be found under the British flag, large accessions were at once made to the native population by refugees from the several surrounding tribes. Since 1843 the colony has made rapid progress; the native tribes as a rule have been loyal, and, although occasional reports from Zululand have alarmed the colonists, it has very seldom been found necessary to send out the volunteer forces on *commando*. Any tendency to insubordination on the part of the resident natives has always been quickly suppressed, and a spirit of disaffection has never become general. In 1879 the colony became the base of operations against the Zulu king Cetywayo, and in 1881 it was for a short time invaded by the Transvaal Boers in connexion with the fighting which arose out of the annexation of the Transvaal in 1877.

(J. W. T.)

NATAL, a city of Brazil, the capital of the province of Rio Grande do Norte, is situated on the eastern bank of the river of that name, 2 miles above the mouth, with its fort in 5° 45′ S. lat. and 35° 13′ 12″ W. long. Though the water on the bar is only 14 feet at low tide, Natal is the first port of any note to the south of Cape Roque, and trades in cotton, sugar, dye-wood, and other local produce. It was founded in 1597. The population is about 11,000.

NATCHEZ, a city and port of entry of the United States, capital of Adams county, Mississippi, lies on the east bank of the Mississippi, 272 miles above New Orleans. Natchez-under-the-Hill, lying on a low alluvial bank, contains the steamboat landing and a few business houses. The main city, Natchez-on-the-Hill, occupies the summit of a bluff which rises nearly 200 feet above the river, and affords a wide view over the cotton plantations of Louisiana. Among the more conspicuous buildings are the city-hall, the court-house, the market-house, the Roman Catholic cathedral, the Jewish synagogue, and a number of handsome churches. There are two large cotton factories and other manufacturing establishments. Cotton dealing is the staple trade. The inhabitants numbered 4454 in 1850, 6612 in 1860, 9057 in 1870, and 7058 in 1880,—the city being in population the second in the State.

Fort Rosalie, erected on Natchez Bluff in 1716 by Bienville, and rebuilt in 1729 after its destruction by the Natchez Indians, continued to be a French trading and military post till 1763, when it passed into British hands and received the name of Fort Panmure. Occupied by the Spaniards from 1779 till 1798, Natchez became at the latter date the capital of the new Territory of Mississippi, retaining that rank till 1820. Its city charter dates from 1803.

NATHANAEL (נְתַנְאֵל, "he whom God gave," equivalent to Nethaniah or the Greek Theodore), a common name in later Old Testament times. It appears in the Gospel of John (i. 45 *sq.*, xxi. 2) as the name of a man of Cana of Galilee, one of the first disciples of Jesus. He is not named in the synoptical Gospels, and the fathers (Chrysostom, Augustine, &c.) do not number him among the apostles;

but his position in the Fourth Gospel has given rise to a prevalent conjecture that Nathanael is the true name of the apostle whose patronymic was Bartholomew (son of Ptolemy). This indeed is mere conjecture, and recent writers have advanced rival hypotheses, *e.g.*, that the name is another form for Mattaniah or Matthew (Hilgenfeld), or that Nathanael is identical with the beloved disciple of the Fourth Gospel (Spāth) or even a mere symbol of Paulinism (Holtzmann).

NATICK, a town of the United States, in Middlesex county, Massachusetts, near the left bank of the Charles River, a few miles to the south-east of Cochituate Lake, and about 18 miles west-south-west of Boston by the railway between that city and Worcester. It is mainly engaged in the manufacture of boots and shoes, but also produces clothing, boxes, and carriages. The population in 1880 was 8480.

Natick ("our land") was in 1650 granted to John Eliot, the Indian "Apostle," for the occupancy of Indians converted to Christianity; and until 1721 the community was governed by a constitution modelled on that of Exodus xviii. Portions of the records, written in the Indian language, are extant. The site of the first Indian church is now occupied by the Unitarian church. Of the Natick Indians only four or five remain, all of mixed blood. The incorporation of the town dates from 1781.

NATIONAL DEBT. Details as to the national debts of individual countries are given under their respective headings, and for the economical principles of the subject the reader is referred to the articles FINANCE and POLITICAL ECONOMY. In the present article the subject will be considered briefly in what may be regarded as its technical aspects,—including the special character of the institution, the different classes of debt, the various methods of raising loans, interest, funding systems, comparative statistics of national debts, methods of estimating the burden of debt, and other points.

National debt is so universal an institution that it has been described as the first stage of a nation towards civilization. A nation, so far as its finances are concerned, may be regarded as a corporate body or even as an individual. Like the one or the other it may borrow money at rates of interest, and with securities, general or special, proportionate to its resources, credit, and stability. But, while in this respect there are certain points of analogy between a state and an individual, there are important points of difference so far as the question of debt is concerned. A state, for example, may be regarded as imperishable, and its debt as a permanent institution which it is not bound to liquidate at any definite period, the interest, unless specially stipulated, being thus of the nature of transferrible permanent annuities. While an individual who borrows engages to pay interest to the lender personally, and to reimburse the entire debt within a certain date, a state may have an entirely different set of creditors every six months, and may make no stipulation whatever with regard to the principal. A state, moreover, is the sole judge of its own solvency, and is not only at liberty either to repudiate its debts or compound with its creditors, but even when perfectly solvent may materially alter the conditions on which it originally borrowed. These distinctions explain many of the peculiarities of national debts as contrasted with those of individuals,—though a nation, like an individual, may by reckless bad faith utterly destroy its credit and exhaust its borrowing powers.

A well-organized state ought to have within itself the means of meeting all its ordinary expenses; where this is not the case, either through insufficiency of resources or maladministration, and where borrowing is resorted to for what may be regarded as current expenses, a state imperils, not only its credit, but, when any crisis occurs, its very existence; in illustration of this we need only refer to the cases of Turkey in Europe and some of the states of Central and South America. Even for meeting emergencies it is not always inevitable that a state should incur debt; its ordinary resources, from taxation or from state property, may so exceed its ordinary expenses as to enable it to accumulate a fund for extraordinary contingencies. This, it would seem, was a method commonly adopted in ancient states. The Athenians, for example, amassed 10,000 talents in the interval between the Persian and the Peloponnesian wars, and the Lacedæmonians are said to have done the same. At Susa and Ecbatana Alexander found a great treasure which had been accumulated by Cyrus. In the early days of Rome the revenue from certain sources was accumulated as a sacred treasure in the temple of Saturn; and we know that when Pompey left Italy he made the mistake of leaving behind him the public treasury, which fell into the hands of Cæsar. In later times, also, the more prudent emperors were in the habit of amassing a hoard. We find that the method of accumulating reserves prevailed among some of the early French kings, even down to the time of Henry IV. This system has long prevailed in Prussia, and even at the present day exists to some extent in reconstituted Germany. Frederick II., when he ascended the throne, found in the treasury a sum of 8,700,000 thalers, and it is estimated that at his death he left behind him a hoard of from 60 to 70 million thalers. And similarly, in our own time, of the five milliards of indemnity paid by France as a result of the Franco-German War, 150 millions were set apart to reconstitute the traditional war-treasury. The German empire, apart from the individual states which comprise it, had in 1882 a debt of about £24,000,000, while its invested funds amounted to £37,390,000, including a war-treasure of £6,000,000. The majority of economists disapprove of such an accumulation of funds by a state as a bad financial policy, maintaining that the remission of a proportionate amount of taxation would be much more for the real good of the nation. At the same time the possession of a moderate war-fund, it must be admitted, could not but give a state a great advantage in the case of a sudden war. In the case of England, apart from the private hoardings of a few sovereigns, there does not seem to have existed any deliberately accumulated public treasure; before the time of William and Mary English monarchs borrowed money occasionally from Jews and from the city of London, but emergencies were generally met by "benevolences" and increased imposts.

All modern states, it may be said, have been compelled to have recourse to loans, either to meet war expenses, to carry out great public undertakings, or to make up the recurrent deficits of a mismanaged revenue. Resources obtained in this way are what constitute national debt proper. Loans have been divided into forced and voluntary. Forced loans can, of course, only be raised within the bounds of the borrowing country; and, apart from the injustice which is sure to attend such an impost, it is always economically mischievous. The loans which the kings of England were wont to exact from the Jews were really of the character of forced loans, though the method has never been used in England in modern times so extensively as on the Continent. There the sum sought to be obtained in this way has never been anything like realized. In 1793, for example, a loan of this class was imposed in France, on the basis of income; and of the milliard (francs) which it was sought to raise only 100 millions were realized. In Austria and Spain, also, recourse has been had at various times to forced loans, but invariably with unsatisfactory results. Other methods of a more or less compulsory character have been and are

made use of in various states for obtaining money, which, as they involve the payment of interest, may be regarded as of the nature of loans; but the debt incurred by such methods is comparatively insignificant, and some of the methods adopted are peculiarly irritating and mischievous. On the other hand, it has occasionally been attempted to raise voluntary loans by appeals to a nation's patriotism; the method has been confined almost exclusively to France. After the revolutions of 1830 and 1848 appeals were thus made to the patriotism of French capitalists to buy 5 per cents direct from the Government at par, at a time when the French 5 per cents were selling at 80; but the results were quite insignificant. Even if the amount sought for by a Government could be obtained on the voluntary principle, the method itself is vicious, withdrawing as it does from the general working capital of the country a sum of serious dimensions. In short, the only economically sound method of meeting expenses which the ordinary resources of a state cannot meet is by borrowing in the open market on the most advantageous terms obtainable. On this normal method of borrowing, loans are divided into different categories, though there are really only two main classes, which may be designated perpetual and terminable. Borrowing in quasi-perpetuity has hitherto been the mode adopted by most states in the creation of the bulk of their debt. Not that any state ever borrows with the avowed intention of never paying off debts; but either no definite period for reimbursement is fixed, or the limit has been so extended as to be practically perpetual, or in actual practice the debt has been got rid of by the creation of another of equal amount under similar or slightly differing conditions as to interest. Of course a state is not bound to retain any part of its debt as a perpetual burden; it is at liberty to liquidate whenever it suits its convenience. This quasi-perpetuity of debt in the case of a state in a sound financial condition involves no hardship upon its creditors, who may at any moment realize their invested capital by selling their titles as creditors in the open money market, it may be at the price they paid, or it may be a little below or a little above it, according to the state of the market at the time. Loans, again, contracted on the terminable principle are of various classes; the chief of these are (1) life annuities, (2) terminable annuities, (3) loans repayable by instalments at certain intervals, (4) loans repayable entirely at a fixed date.

From the time of William III. life and terminable annuities have been a favourite mode in England either of borrowing money or of commuting, and thus gradually paying off, the existing funded debt. At first, and indeed until comparatively recent times, the system of life annuities resulted in serious loss to the country, owing to the calculation of the rate of annuity on too high a scale, a result arising from imperfect data on which to base estimates of the average duration of life. The system of life annuities was sometimes combined in England with that of perpetual annuities, or interest on the permanent debt,—the life annuity forming a sort of additional inducement to lenders of limited means to invest their money. At one time the form of life annuities known as tontine was much in vogue both in England and France, the principle of the tontine being that the proceeds of the total amount invested by the contributors should be divided among the survivors, the last survivor receiving the whole interest or annuity. The results of this system were not, however, encouraging to the state. In England, at least, the terminable annuity has been a favourite mode of borrowing from the time of William III.; it has been generally conjoined with a low rate of permanent interest on the sum borrowed. Thus in 1700 the interest on the consolidated debt amounted to only £260,000, while the terminable annuities payable amounted to £308,407. In 1780 a loan of 12 millions was raised at 4 per cent. at par, with the additional benefit of an annuity of £1, 16s. 3d. per cent. for eighty years. Even so late as the Crimean War in 1855, a loan of 16 millions at 3 per cent. at par was contracted, the contributors receiving in addition an annuity of 14s. 6d. per cent. for thirty years. Latterly, however, this beneficiary system has been abandoned, though the system of terminable annuities has received increased favour, especially as a means of reducing the funded debt. Of the total debt of England in 1882, upwards of 35½ millions were in terminable annuities, while in 1883 the sum was only £29,492,125.

The third method of contracting terminable loans, that of gradual repayment or amortization within a certain limit of years, has been a favourite one among certain nations, and specially commends itself to those whose credit is at a low ebb—as Turkey, Russia, and Egypt. When the final term of repayment is fixed upon, a calculation is easily made as to how much is to be paid half-yearly until the expiry of the term, so that at the end the whole, principal and interest, will have been paid. At first, of course, the amount paid will largely represent interest, but, as at each half-yearly drawing of the numbers of the bonds to be finally paid off the principal will be gradually reduced, there will be more and more money set free from interest for the reduction of the actual debt. This method, as we have said, has its advantages, and when conjoined with stipulations as to liberty of conversion to debt bearing a lower rate of interest than that originally offered, and when the bonds are not issued at a figure much below par, might be the most satisfactory method of raising money for a state under certain emergencies. What is known as the "Morgan loan" of France in 1870 was contracted on such conditions.

The last form of temporary loan, that repayable in bulk at a fixed date, is one which, when the sum is of considerable amount, is apt to be attended with serious disadvantages. The repayment may have to be made at a time when a state may not be in a position to meet it, and so to keep faith with its creditors may have to borrow at a higher rate in order to pay their claims. It has, however, worked well in the United States, most of the debt of which has been contracted on the principle of optional payment at the end of a short period, say five years, and compulsory payment at the end of a longer period, say twenty years. Thus the loan of 515 millions of dollars contracted in 1862 was issued on this principle, at 6 per cent., and so with other loans between that year and 1868. In European states, however, the risks of embarrassment are too great to permit of the application of this method on an extensive scale; and for loans of great amount the methods most likely to yield satisfactory results are loans bearing quasi-perpetual interest, or those repayable by instalments on the basis of half-yearly drawings within a certain period.

What are known as lottery loans are greatly favoured on the Continent, either as an independent means of raising money, or as an adjunct to any of the methods referred to above. These must not be confounded with the lottery pure and simple, in which the contributors run the risk of losing the whole of their investment. The lottery loan has been found to work well for small sums, when the interest is but little below what it would have been in an ordinary loan, and when the percentage thus set aside to form prizes of varying amounts forms but a small fraction of the whole interest payable. The principle is that each contributor to such a loan has a greater or less chance of drawing a prize of varying amount, over and above the repayment of his capital with interest.

What are known as exchequer bills and treasury bills may be regarded as loans payable at a fixed period of short duration, from three months upwards, and bearing very insignificant interest, even so low as $\frac{1}{2}$ per cent. They are a useful means of raising money for immediate wants and for local loans, and form handy investments for capitalists who are reserving their funds for a special purpose. Exchequer bonds are simply a special form of the funded debt, to be paid off generally within a certain period of years.

There are two principal methods of issuing or effecting a loan. Either the state may appeal directly to capitalists and invite subscriptions, or it may delegate the negotiation to one or more bankers. The former method has been occasionally followed in France and Russia, but in practice it has been found to be attended with so many disadvantages to the borrowing state or city that the best financial authorities consider it unsound. The great banking-houses have such a command over the money-market that it is difficult to keep even a direct loan out of their hands. The majority of loans, therefore, are negotiated by one or more of these houses, and the name of Rothschild is familiar to every one in connexion with such transactions. By this method a borrowing state can assure itself of having the proceeds of the loan with the least possible delay and with the minimum of trouble. A loan may be issued at, above, or below par, though generally it is either at or below par,—"par" being the normal or theoretical price of a single share in the loan, the sum which the borrowing Government undertakes to pay back for each share on reimbursement, without discount or premium. Very generally, as an inducement to investors, a loan is offered at a greater or less discount, according to the credit of the borrowing Government. England, for example, may borrow at any time at par or at a mere fraction below it, while a Central-American state might find difficulty in raising a small loan at 50 per cent. discount. Sometimes a state may offer a loan to the highest bidders; for example, the city of Auckland in 1875 invited subscriptions through the Bank of New Zealand to a loan of £100,000 at 6 per cent.; offers were made of six times the amount, but only those were accepted which were at the rate of 98 per cent. or above. The rate of interest offered generally depends on the credit of the state issuing the loan. England, for example, would have no difficulty in raising any amount at 3 per cent. or even less, while less stable states may have to pay 8 or 9 per cent. The nominal percentage is by no means, however, always an index of the cost of a loan to a state, as the history of the debt of England disastrously shows. During last century various expedients were employed, besides that of terminable annuities already referred to, to raise money for the great wars of the period, at an apparently low percentage. For example, from 3 to 5 per cent. would be offered for a loan, the actual amount of stock per cent. allotted being sometimes $107\frac{1}{2}$ or even 111; so that between 1776 and 1785, for the £91,763,842 actually borrowed by the Government, £115,267,993 was to be paid back. In 1797 a loan of £1,620,000 was contracted, for every £100 of which actually subscribed, at 3 per cent., the sum of £219 was allotted to the lender. In 1793 a 3 per cent. loan of $4\frac{1}{2}$ millions was offered at the price of £72 per cent., the Government thus making itself liable for £6,250,000. Greatly owing to this reckless method the debt of Great Britain in 1815 amounted to over 900 millions. France in this respect has been quite as extravagant as England; many of her loans during the present century have been issued at from $52\frac{1}{2}$ to 84 per cent., one indeed (1848) so low as 45 per cent.,—as a rule with 5 per cent. interest. The enormous and embarrassing increase of the French debt during the present century is doubtless greatly due to this disastrous system. Nearly every European state and most of the Central and South American states have aggravated their debts by this method of borrowing, and got themselves into difficulty with their creditors. Both Turkey and Egypt are notable examples, while states such as Austria and Italy have been compelled to resort to various expedients to reduce their enormous liabilities. Financiers almost unanimously maintain that in the long run it is much better for a state to borrow at high interest at or near par, than at an apparently low interest much below par. A state of even the highest rank may find itself in the midst of a crisis that will for a time shake its credit; but when the crisis is past and its credit revives it will be in a much more sound position with a high interest for a debt contracted at par than with a comparatively low interest on a debt much in excess of what it really received. If a state, for example, borrows at par at 6 per cent. when its credit is low, it may easily when again in a flourishing condition reduce the interest on its debt to 4 or even 3 per cent. The United States Government has actually done so with the debt it had to contract at the time of the civil war. This method of reducing the burden of a debt is evidently no injustice to the creditors of a Government, when used in a legitimate way. A state is at liberty at any time to pay off its debts, and, if it can borrow at 3 per cent. to pay off a 6 per cent. debt, it may with perfect justice offer its creditors the option of payment of the principal or of holding it at a reduced interest. Government debts are, however, sometimes reduced after a fashion by no means so legitimate as this; we need only refer to Turkey, where both principal and interest have been enormously reduced on a debt on which little or no interest was ever paid. Other states have been even more unprincipled, and have got rid of their debts at one sweep by the simple method of repudiation; some of the States of the American Union are notorious examples of this easy method.

When a state has a variety of loans at varying rates of interest, it may consolidate them into a single debt at a uniform interest. For example, in 1751 several descriptions of English debt were consolidated into one fund bearing a uniform interest of 3 per cent., an operation which gave origin to the familiar term "consols" ("consolidated funds"). In the early days of the English national debt, a special tax or fund was appropriated to the payment of the interest on each particular loan. This was the original meaning of "funds," a term which has now come to signify the national debt generally. So also the origin of the term "funded" as applied to a debt which has been recognized as at least quasi-permanent, and for the payment of the interest on which regular provision is made. Unfunded or floating debt, on the other hand, means strictly loans for which no permanent provision requires to be made, which have been obtained for temporary purposes with the intention of paying them off within a brief period. Exchequer and treasury bills are included in this category, and such other moneys in the hands of a Government as it may be required to reimburse at any moment. Where a Government is the recipient of savings banks deposits, these may be included in its floating debt, and so also may the paper-money which is issued so largely by some Governments. The unfunded debt of England is comparatively small, while in Austria and some other states it has attained formidable and embarrassing dimensions. A state with an excessive floating debt must be regarded as in a very critical financial condition.

National debt, again, is divided into external and internal, according as the loans have been raised within or without the country,—some states, generally the smaller ones, having a considerable amount of exclusively internal debt, though it is obvious that the bulk of national debts are both external and internal.

We referred above to various ways of reducing the burden of a debt, and also to methods of contracting loans by which within a certain period they are amortized or extinguished. Most states, however, are burdened with enormous quasi-permanent debts, the reduction or extinction of which gives ample scope for the financial skill of statesmen. A favourite method of accomplishing this is by the establishment of what is known as a sinking fund, formed by the setting aside of a certain amount of national revenue for the reduction of the principal of the debt. Unless carefully managed, a sinking fund is likely to prove a snare. Where it is the genuine result of surplus revenue, and not of money which is in reality borrowed, the only sure method of making it accomplish its purpose is to sink it yearly in the discharge of debt. Where it is allowed to accumulate "at compound interest," as in Pitt's famous experiment, there is great danger of its being diverted from its purpose, and the debt increased instead of diminished. In 1786 a "new sinking fund" was established in England, and certain commissioners appointed to carry its object into effect. With certain modifications in 1829, the fund continued in force till 1875, when another "new sinking fund" was established by which ultimately almost 29 millions were set aside for the annual service of the debt, the difference between the sum actually required and this fixed amount being applied to purchase of stock. This fund was to continue in operation for ten years. Meantime Mr Childers, chancellor of the exchequer, has had an Act passed (1883) for the creation of a large amount of terminable annuities (from five to twenty years), by the operation of which £173,000,000 of stock will be cancelled in twenty years. The existing 28 millions (over 29 millions in 1883–4) will continue to be the yearly charge of the debt, but, as the annuities into which it is proposed to convert a large portion of the debt fall in, more and more of this sum will be set free for the reduction of the principal of the debt. In the United States the large surplus of revenue over expenditure is regularly applied to the reduction of the debt, so that the enormous liabilities incurred owing to the civil war are being reduced with unprecedented rapidity. The sinking fund also plays a prominent part in the new arrangements which have been made with the creditors of Turkey and Egypt.

Questions as to the policy of a state contracting debt belong properly to the general subjects of finance and political economy; here we shall briefly deal with actual facts, the progress of the leading national debts, and their present comparative magnitudes. Debts of different countries

The debt of the United Kingdom at the Revolution in 1688 amounted to only £664,263, with an annual charge of £39,855. During the reign of William III. this increased to the comparatively large sum of £12,767,000, with an annual charge of £1,215,324, which at the accession of George I. had grown to £36,000,000 and United Kingdom.

£3,063,135 respectively. In 1727 the capital had increased to £53,979,000, while by reduction of interest the annual charge had diminished to £2,360,930. Partly by the operation of the sinking fund, the debt in 1739 had decreased by upwards of 7 millions, but the wars which followed left it at the treaty of Aix-la-Chapelle in 1748 at the sum of £77,488,940. By the end of the Seven Years' War, however, in 1763, the debt had risen to £133,287,940, besides terminable annuities, and the annual charge to £5,032,732. At the commencement of the American War, 1775, the debt had fallen to £126,842,800, but as a result of that war this was more than doubled, and the burden had grown to £273,000,000, including the capitalized value of terminable annuities. After a diminution of about 10 millions during the nine years' peace, the long French wars, which terminated in 1815, left the country burdened with a debt of over 900 millions, at an annual charge of £32,645,618. With various fluctuations during the next forty years, the debt gradually diminished to a little over 800 millions. The two years of war with Russia cost upwards of 30 millions, and in 1857 the capital sum had risen to £838,900,000 and the annual charge to £28,681,177. In 1870 it had fallen again to 800 millions, which in 1883 had diminished to £756,376,519, with an annual charge of £29,678,672, including terminable annuities and the charge thereon, as well as the sinking fund. As we have already pointed out, the actual capital of the British debt does not represent by any means the sums actually received by the state. During the past and the early years of the present century enormous sums were borrowed at a price far below par, the difference adding many millions to the actual burden of the debt. At the same time some relief has been obtained from this burden by judicious conversions into lower-priced stock and the creation of terminable annuities. For the relations between the South Sea Company and the Bank of England and the British national debt, we must refer to the articles BANKING and FINANCE. In the above estimates we have taken no account of the indebtednesses of cities, counties, and other local divisions, which can scarcely be regarded as included in the debt of the nation as a whole. Were these sums added they would increase the total amount of the debt by about 150 millions.

France. One peculiarity of the national debt of France is that it is reckoned, not according to capital, but according to rente or interest; so that any estimates based on rente must be regarded as approximate. Another peculiarity is the minute distribution of the consolidated debt among a multitude of creditors, most of whom are French; this arises from the fact that the shares in French debt may be subdivided into minute parts, and an investor may thus purchase a few francs' worth of rente. Thus in 1883 the number of holders of rente was over 4,000,000. The debt of France can be traced as far back as 1375, and at the death of Louis XIV. in 1715 it is estimated to have amounted to a capital of £124,000,000, though this was arbitrarily reduced in the following year to 80 millions. The republican Government of 1793 cancelled nearly the whole of the then existing debt, reducing it to a capital of £32,000,000, with a rente of £1,600,000. During the empire, notwithstanding Napoleon's extensive wars, the debt had only grown to £70,645,000, including a floating debt of 20 millions. Under the Bourbons, what with war-levies and constant deficits, it grew rapidly, and in 1830 stood at £141,770,000. To this the Orleans dynasty added 40 millions, leaving the debt in 1848 at 182 millions. During the four years of the republic this grew to £245,250,000, while the enormous deficits and the wars of the second empire raised it to £550,000,000 in December 1870. The further cost of the German war, with its enormous indemnity and the foreign occupation of 1870-73, added upwards of 300 millions to this. Since then the French debt has steadily grown, and in 1883 stood (capitalizing all classes of debt) at about £1,000,000,000, with an annual charge of £52,722,300,—the largest in the world.

Austria. In 1763, at the end of the Seven Years' War, Austria had a debt of only £15,000,000; but, as it is a country of almost constant deficits, this sum has rapidly increased. In 1815 it was £82,500,000; in 1830, 108 millions; in 1848, 125 millions; in 1862, after the French war, £252,671,860, to which the war with Prussia added 40 millions in 1866. Since then it has grown apace, and in 1883 stood at £380,000,000, including floating debt, paper-money, and Austria's special liabilities, amounting to £105,700,000, but excluding the special debt of Hungary, which amounted to over 104 millions; Hungary, besides, contributes three-tenths to the interest of the common debt, this interest in 1883 amounting to £12,024,070, in addition to over 2 millions for Austria's special debt.

Germany. The debt of Prussia in 1800 was only £5,250,000, which as a result of the French wars grew by 1820 to 31 millions. By 1842 10 millions were paid off, but in 1866 it had risen to 42 millions, partly from deficits, partly from war preparations, and partly from money sunk in the construction of railways. The war with Austria, and the annexations in 1866, raised it by 1870 to £56,400,000. Since then it has nearly doubled, and in 1882 had reached the sum of £102,984,071, with an annual charge of £4,381,032. Much of the debt of Prussia has, however, been contracted for railways and the development of the resources of the country, and is in fact nearly covered by the revenue of the state-railways, domains, and mines. The German empire, as such, had no debt at the time of its re-establishment in 1870, though one has since been created; in 1883 the total funded debt was £18,500,000 at 4 per cent. interest. There was also an unfunded debt consisting of state treasury bills amounting to £7,698,210. The expenses of the French war were far more than covered by the indemnity, while the various invested funds of the empire amounted to £37,390,528. Besides Prussia, each of the German states has its own special debt. In all these amounted to about 170 millions, most of this sum having been borrowed for the construction of railways, so that the actual burden is comparatively small. Thus the total debt of the empire and of the states composing it is only a little over 300 millions.

It is difficult to obtain any trustworthy figures as to the debt of Russia. The history of its finance is a history of almost continual deficits, largely covered since the time of Catherine II. by the issue of paper roubles, which at her death amounted to about 30 million pounds sterling, and in 1817 to 125 millions. The total debt was first stated for 1853, when it was given as 125 millions, including paper-money. In 1858, after the Crimean War, it was 240 millions, and in 1869, including the floating debt, 300 millions. In 1880 it was estimated at 640 millions, one-third of which was paper roubles. Were the depreciated rouble taken at par, the sum would be nearly half as much again. The interest on the debt in 1880 amounted to 17 millions, and in the budget for 1882 the total charge of the debt was set down at over 28 millions.

In 1876 the debt of Turkey stood at 296 millions, but since then, by a process of reduction, it has been brought down to 150 millions, besides an internal debt estimated at 20 millions.

The united kingdom of Italy began in 1860 with a debt of $97\frac{1}{2}$ million pounds sterling, which, mainly through continual deficits, but partly by the construction of railways, had grown to $446\frac{1}{2}$ millions in 1881, with a net interest of 17 millions, a heavy burden on one of the poorest countries of Europe.

Like Austria, Spain has been a country of constant deficits, combined with frequent repudiations and chronic inability to meet the claims of creditors. Spain was deeply in debt so long ago as the 16th century; the amount in 1745 was 9 millions sterling, which was repudiated by Ferdinand VI. A commission in 1822 reported the debt at 140 millions, but in 1822 a second junta reduced it to 52 millions. In 1851, with the floating debt, the amount was 113 millions, one half of which was declared passive, bearing no interest. In twenty years this had more than doubled, being in 1870 £237,400,000, with an annual charge of £6,735,000. In 1881 the capital sum had increased to 512 millions, but by a process of conversion this was to be reduced to 240 millions, according to official statement, bearing an annual charge of £9,500,000.

Portugal has for its size a large debt, the result also of vicious financial administration. It began in 1796 with £900,000, which in 1854 rose to 20 millions, in 1866 to 48 millions, in 1871 to £64,333,000, and in 1881 to £97,512,000, with an annual charge of £3,065,285.

Greece began her independence by becoming a debtor in 1824 for £800,000, and her borrowings since have loaded the little kingdom with a debt of 15 millions, the interest on which has never been regularly and fully paid. Part of the debt is guaranteed by England, France, and Russia.

The debt of Holland began in the 16th and 17th centuries in her struggle with Spain and wars with England, and in 1778 the Dutch were oppressed with a debt of 62 millions, which by 1814 had risen to 144 millions, the annual charge per head of population being over 30s. By 1851 the capital was reduced to $102\frac{1}{2}$ millions, which has gone on steadily decreasing, and in 1882 the capital sum was £78,442,370, with an annual interest of £2,419,222, being about 12s. per head, though the revenue of the state railways makes it somewhat less. A sinking fund of £833,000 is annually devoted to the redemption of the debt. The debt of Belgium began with 10 millions taken over from Holland after 1830, which, after growing to 39 millions and again falling by the operation of the sinking fund to £24,400,000 in 1865, has since steadily grown to about 72 millions in 1882, including the railway purchases, the annuities granted for which represent about 13 millions. Most of the remainder of the debt is covered by the proceeds of the various public works for which it has been raised.

The debt of Denmark was £4,150,000 in 1821. Partly through deficits, partly through war with Prussia, and partly owing to the construction of state railways, this grew to £14,862,465 in 1865. This declined to £9,629,257 in 1880, but subsequent loans raised it to over 11 millions in 1882, the annual charge being £554,400. So much of the debt, however, is caused by productive investments that the annual burden is only 2s. a head. Only £700,000 of the debt is external.

The existing debt of Sweden began with a railway loan of £1,228,575 in 1858, and nearly all her subsequent loans have been contracted for similar purposes, the total debt in 1882 being $12\frac{1}{2}$ millions. So much of this is covered by the proceeds of the railways that the annual burden is less than 9d. per head of population.

Norway. The debt of Norway, which has grown from £1,656,315 in 1871 to £5,806,222 in 1882, has also been largely contracted for railways, though the net annual charge per head is 2s. 6d.

Switzerland. Switzerland in 1882 had a nominal debt of £1,477,881, more than covered by the "federal fortune" or property belonging to the state. The separate cantonal debts amounted in all to 12 millions sterling, in most cases also covered by the proceeds of cantonal property.

United States. Outside Europe we can only refer to the progress of the debts of the United States and India. The former began their career as a federal republic with a debt of 15 millions sterling (1791), on which there was little increase till 1816, when it reached 25 millions, which in 1835 was almost extinguished. The debt, however, rose again, but never exceeded 14 millions till 1860, the year before the civil war, when it reached 18 millions. During the next four years the debt rose rapidly, and after the conclusion of the war in 1866 the country was saddled with a debt of £556,685,175. This has gone on decreasing since with wonderful rapidity, on account of the systematic application of the large surplus revenue to its reduction, and in 1882 it had sunk to £382,662,598, being at the rate of over 10 millions a year. At this rate the debt would be extinguished within forty years. Each of the States has, besides, a debt of its own, these amounting to about 57 millions sterling in 1882.

India. The debt of India, as might be expected from its peculiar conditions, far exceeds that of any other British dependency. During the early years of the century there were considerable deficits in the revenue owing to the various wars, and these by 1820 had reached over 5 millions. In 1834, taking the nominal value of the rupee as 2s., there was a total debt of £41,350,952. When the administration was taken over by the imperial Government there was a debt of 81 millions (1859), which, with slight fluctuations, has gone on increasing, until in 1882 it had reached £156,820,614, with interest of about 4½ millions. Were the Government guarantees of railway and other undertakings added, this would raise the liabilities of the country to about 250 millions. The large receipts from productive investments, however, considerably reduce the net burden of the debt, which has fallen from 9½d. a head in 1871 to about 5d. at the present time.

In the following table we give a list of the leading national debts (1882 and 1883), with various other items, by which some idea may be formed of their comparative burdensomeness:—

Table of Leading National Debts.

	Debt.	Per Head of Population.	Annual Charges.	Per Head of Population.	Revenue per Head	Expenditure per Head.	Imports per Head.	Exports per Head.	Imports and Exports per Head.

The total debt of the British empire may be set down at about 1050 millions sterling, or at the rate of about £4, 6s. per head of the population of the empire. The gross debt of all the states of the world is estimated at about 5200 millions in 1882, or about £6 per head. In some of the Central and South American states it is scarcely possible to obtain the actual amount and burden of the debt, as the interest has remained unpaid for years. For example, the debt of Costa Rica is equal to £22, 8s. per head, but as no interest has been paid for years, the actual burden is nil. In the case of Honduras, if the overdue interest were added to the outstanding debt, the burden per head would be something like £38. Most of those states, however, have been defaulters, and have sought to escape the burden of their liabilities by not meeting them. The classification given by Mr Dudley Baxter in 1874 (*Jour. Stat. Soc.*) is still (except as regards the United States) essentially correct. He classified the borrowing states into four categories, according to the rate of interest on the market-price of their stocks:—(1) low interest states, 3 and 4 per cent.—United Kingdom, Denmark, Holland, Belgium, Germany, India, Canada, Australasia, Sweden; (2) moderate interest, 5 to 6½ per cent.—Morocco, United States, Brazil, Russia, France, British African colonies, Chili, Argentine Republic; (3) high interest states, 6½ to 10 per cent.—Portugal, Japan, Hungary, Austria, Colombia, Roumania, Uruguay, Italy, Cuba, Egypt, Peru, Ecuador, Turkey (states whose expenditure exceeds their income, and whose other circumstances show some risk to lenders); (4) excessive interest, 14 to 66 per cent.—Guatemala, Bolivia, Spain, Mexico, Costa Rica, Paraguay, Venezuela, San Domingo, Greece, Honduras (states of unsettled governments and finances, and threatened or actual default of interest). Most of the last class have been or are defaulting states, and among them, in this respect, should be classed Peru and Ecuador.

The above table cannot be said to represent the real relative amounts and burdens of the various national debts. For example, the interest per head of the British debt is 17s., while that of Russia is 5s. 10d., of the United States 7s., of Australasia 31s. 9d., and of Egypt 18s. 4d. But it is evident that these figures give no adequate idea of the real burden,—that the average Englishman can more easily afford to pay his 17s. a year, the Australasian his 31s. 9d., and much more the average American his 7s., than the average Russian his 5s. 10d., or the poor Egyptian his 18s. 4d. It has been sought (Fenn's *Compendium*) to show the real comparative indebtedness by readjusting the capital sums on a 5 per cent. basis. In this way the British debt would be represented by about 460 millions; that of France by 780 millions; Austria, 226 millions; Russia, 485½ millions; Italy, 432½ millions; United States, 225 millions; India, 118½ millions; Belgium, 53½ millions; Holland, 50 millions; Japan, 93 millions; Egypt, 99 millions. If, moreover, from these sums be deducted the amount covered by the net earnings of reproductive investments, a considerable reduction would have to be made in some cases in the amounts to be provided for by taxation. In the case of Prussia, for example, the whole of the debt in 1882 was met by the proceeds of reproductive investments. The Cape Colony, on the 5 per cent. basis, had only half her nominal debt to provide for by taxation, and so more or less with the Australian colonies; the debt of India would thus be reduced by one-third, of Belgium by about one-half, Norway the same, Sweden by about nine-tenths. Perhaps the most satisfactory test, according to the above table, of the relative burden of the various debts, is a comparison between the interest per head and the annual value per head of exports. Compare, for example, Great Britain with 17s. per head of interest and £8, 8s. of exports, Australasia 31s. 9d. and £17, 8s., Canada 8s. 8d. and £4, 6s. 11d., the United States 7s. and £3, 1s. 7d., and Holland 11s. 9d. and £12, 13s. with France and its £1, 8s. of interest per head and £3, 16s. 8d. of exports, Russia 5s. 10d. and 15s. 9d., Austria-Hungary 11s. 8d. and £1, 17s. 10d., Spain 11s. and £1, 8s. 5d., Egypt 18s. 4d. and £2, 8s., Portugal 12s. 11d. and 19s. 5d., Japan 3s. and 3s. 6d.,—and some idea will be obtained of the different conditions of the countries to meet their national liabilities. But even this comparison does not give anything like a complete idea of the real burden of national debt, and should be supplemented by reference to the total income of each nation from all sources and the total amount of its capital, supposing all its assets were realized. Estimates, which can only be regarded as roughly approximate, have been made of the value of national capital of the leading states and the amount of their national income. Taking, then, the capital of the United Kingdom at 10,000 millions sterling, we find that the national debt, 756 millions, bears to this the proportion of only a little over 7½ per cent.; and even if we added the local debts the proportion would be only about 9 per cent. Taking again the national income at 1200 millions, we find that the annual charge of the debt is only 2½ per cent. of this sum, and even if we added the charges of the local

debts the percentage would scarcely be above 3. The whole national and local debt could be paid off by about two-thirds of a year's income; as they could be also by the produce of three years' exports.

The national capital of France may be roughly estimated at 7500 millions sterling, to which the debt, 960 millions, bears the large proportion of 12·8 per cent., while if the local debts be included the proportion rises to 14½ per cent. The income of France may be taken at 950 millions, to which the annual charge of the debt bears the proportion of 3·65 per cent., and that of the local debts would raise it to 4 at least. It would take nearly five years even of the proceeds of the "general exports" of France to pay off the national debt.

The national capital and income of the United States increase with unexampled rapidity. The former cannot be less at present than 7000 millions, and the latter 1500 millions (more than even that of the United Kingdom). The national debt is 5 per cent. of the former, and the total federal and State debts only 6 per cent., while the interest (including that of the Pacific Railway loans, for which there are reimbursements), £17,775,000, is only 1·2 per cent. of the rapidly increasing income. One-fourth of a year's income would pay off the whole of the debt.

If we take the total debts of the German empire and all the states at 300 millions, and the national capital at 4500 millions, we find the former only 6 per cent. of the latter. Belgium and Holland are equally favourably situated in this respect, while in the Scandinavian countries the proportion of debt to national capital is only about 2 per cent. Coming to Russia, we find the debt bears the enormous proportion of 23 per cent. to the approximate national capital, while the interest is 5 per cent. of the national income. Estimating the latter at 560 millions, we see that one year would not suffice to pay off the 640 millions of debt. Austria-Hungary is not quite so bad, as the debt is only 17 per cent. of the capital, and it could be nearly paid off by a year's income. Italy seems even in a worse state than Russia, as her debt is estimated at 27 per cent. of her capital, which it would take two years' income to pay off, while Spain and Portugal (even with the greatly reduced principal of the former) have a combined debt amounting to 29 per cent. of their united national capitals. India and the British colonies are nearly as favourably situated in this respect as the mother-country, while the rapid development of the enormous resources of Canada and the Australian colonies tends constantly to diminish the proportion of debt to capital.

Other elements which ought to be taken into consideration in estimating the real burden of national debt, besides the above and the increased development of the world's resources, are the increase of population and the depreciation of the precious metals. Thus, while the annual charge of the British debt per head was 34s. 8d. in 1815, it was only 16s. 10d. in 1882, and this not solely from the decrease of the debt, but even more largely by the increase of the population. Moreover, owing to the decreased value of money, 16s. 10d. in 1882 is in reality very considerably less than the half of 34s. 8d. in 1815. Thus even by the operation of the unearned increment, not to speak of the increasing value of reproductive investment, the natural tendency is for the actual burden of national debt to decrease every year, unless it is recklessly increased by fresh loans.

NATURALIZATION. See ALIEN.

NAUDÉ, GABRIEL (1600–1653), French librarian and scholar, was born at Paris in February 1600. An intense love for books caused him to accept, when only twenty years of age, the appointment of librarian to the president De Mesmes, whom he left in 1626 to finish his medical studies at Padua. On returning to Paris in 1628 he was chosen to deliver a panegyrical discourse on the medical school. The credit thus acquired brought him under the notice of Cardinal Bagni, who took him to Rome and gave him charge of his collection. On Bagni's death in 1641 he became librarian to Cardinal Barberini, under whose patronage he commenced a wearisome controversy with the Benedictines concerning the authorship of *De Imitatione Christi*. Richelieu, wishing to secure the services of Naudé, recalled him to Paris in 1642, but, the great minister dying a few months later, Naudé accepted a similar offer on the part of Mazarin, and for the next ten years his unwearied energy was directed to the task of bringing together that noble assemblage of books since known as the Bibliothèque Mazarine (see LIBRARIES, vol. xiv. p. 525), making for the purpose expeditions to all parts of Europe. The troubles of the Fronde caused him to assent to the wish of Queen Christina that he should become her librarian at Stockholm. He was not happy in Sweden, however, and on Mazarin's appeal that he should reform his scattered library Naudé returned at once. But his health was altogether broken, and he died on the journey at Abbeville in July 1653. The friend of Gui Patin, Gassendi, and all the liberal thinkers of his time, Naudé was no mere bookworm; each of his books shows traces of the critical spirit which made him a worthy member of the company of humorists and scholars who prepared the way for the better known writers of the "siècle de Louis XIV."

Including works edited by him, a list of ninety-two pieces is given in the *Naudæana*. The chief are *Le Marfore, ou discours contre les libelles*, Paris, 1620, very rare, reprinted 1868; *Instruction a la France sur la vérité de l'histoire des Frères de la Roze-Croix*, 1623, 1624, displaying their impostures; *Apologie pour tous les grands personnages faussement soupçonnez de magie*, 1625, 1652, 1669, 1712,—Pythagoras, Socrates, Thomas Aquinas, and Solomon are among those defended; *Advis pour dresser une bibliothèque*, 1627, 1644, 1676, translated by J. Evelyn, 1661, full of sound and liberal views on librarianship; *Addition à l'histoire de Louys XI.*, 1630 (this includes an account of the origin of printing); *Bibliographia politica*, Venice, 1633, &c., in French 1642, a mere essay of no bibliographical value; *De studio liberali syntagma*, 1632, 1645, a practical treatise found in most collections of directions for studies; *De studio militari syntagma*, 1637, esteemed in its day; *Considérations politiques sur les coups d'état*, Rome [Paris], 1639, first edition rare, augmented by Dumay, 1752 (this contains an apology for the massacre of St Bartholomew); *Biblioth. Cordesianæ Catalogus*, 1643, classified; *Jugement de tout ce qui a été imprimé contre le Card. Mazarin* [1649], Naudé's best work, and one of the ablest defences of Mazarin; it is written in the form of a dialogue between Saint-Ange and Mascurat, and is usually known under the name of the latter.

NAUMACHIA, the Greek word denoting a naval battle, was used by the Romans as the name for mimic sea-fights which were shown as a spectacle to the public. The first that is recorded was given by Julius Cæsar on an artificial lake which he constructed in the Campus Martius. After this naumachiæ became a favourite spectacle for the emperors to give to the people. Claudius made a great one on the Lacus Fucinus, Nero another in the amphitheatre at Rome. Gladiators or condemned criminals fought in these battles; in later times even volunteers took part in them. The combatants were often dressed in costume: Augustus showed a naumachia of Athenians and Persians; Titus acted a sea-fight between Corinth and Corcyra.

NAUMBURG, the chief town of a circle in the district of Merseburg, Prussian Saxony, and the seat of the provincial law courts, is pleasantly situated on the Saale, near its junction with the Unstrut, in the centre of an amphitheatre of vine-clad hills. The cathedral, an imposing building in the Romanesque Transition style (1207–42), has a Gothic choir at each end, and contains some interesting mediæval sculptures. There are also three other Protestant churches, a Roman Catholic church, a gymnasium, a real-school, an orphanage, and two or three hospitals. The town-hall was originally the residence of the bishop. The inhabitants, who in 1880 numbered 17,868, are chiefly employed in producing wine (12,000 gallons yearly), but also manufacture cotton and woollen fabrics, chemicals, combs, and leather. Trade, facilitated by the navigable river, is

mainly concerned with wine, grain, vegetables, and dried fruit. An annual fair, founded by the emperor Maximilian in 1514, is still held here, but is now of little importance. Near Naumburg are Kösen, a favourite watering-place, and the celebrated school of Schulpforta, which has perhaps the strongest claim to the title of a German Eton.

In the 10th century Naumburg was a stronghold of the margraves of Meissen, who in 1029 transferred to it the bishopric of Zeitz for protection against the Wends. In Saxon history Naumburg is memorable as the scene of various treaties; and in 1561 an assembly of Protestant princes was held there, which made a futile attempt to cement the dissensions of the Protestants on doctrinal points. In 1564 the last bishop died, and the bishopric fell to the elector of Saxony. In 1631 the town was taken by Tilly, and in 1632 by Gustavus Adolphus. It became Prussian in 1814. An annual festival, with a procession of children, is referred to an apocryphal siege of the town by the Hussites in 1432, but is probably connected with an incident in the Brothers' War, between elector Frederick of Saxony and his brother Duke William (1447–51). Lepsius the antiquary and his more distinguished son the Egyptologist were born at Naumburg.

NAUPACTUS. See LEPANTO.

NAUPLIA, a town in the Peloponnesus, at the head of the Argolic Gulf. In the classical period it was a place of no importance, and when Pausanias lived, about 150 A.D., it was deserted. At a very early time, however, it seems to have been of greater note, being the seaport of the plain in which Argos and Mycenæ are situated. A hero Nauplius took part in the Argonautic expedition; another was king of Eubœa. The mythic importance of the town revived in the Middle Ages, when it became one of the chief cities of the Morea. It was captured in 1211 by Godfrey Villehardouin with the help of Venetian ships; a French dynasty ruled in it for some time, and established the feudal system in the country. In 1388 the Venetians bought Argos and Nauplia. In the wars between Venice and the Turks it often changed masters. It was given to the Turks at the peace concluded in 1540; it was recaptured by Venice in 1686, and Palamidhi on the hill overhanging the town was made a great fortress. In 1715 it was taken by the Turks; in 1770 the Russians occupied it for a short time. The Greeks captured it during the war of independence on December 12, 1822, and it was the seat of the Greek administration till 1833, when Athens became the capital of the country. The population in 1879 was 4598.

NAUTILUS. For the Paper Nautilus (*Argonauta argo*) see vol. vi. p. 750; and for the Pearly Nautilus (*N. pompilius*) see vol. xvi. p. 670 *sq.*

NAVARINO, or NEOCASTRO, a seaport of the Morea, Greece, in the nomarchy of Messenia, stands on the south shore of the Bay of Navarino, in 36° 54′ N. lat. and 21° 41′ E. long. It consists of a citadel, situated on a high rock, and a lower town,—the whole being surrounded by a wall. The population is under 2000. The bay, one of the best harbours in Greece, about 4 miles in length by 2 in breadth, with a depth ranging from 12 to 26 fathoms, is protected towards the west by the long and narrow island of Sphagia, the ancient Sphaeteria, to the south-east of which lies the entrance, now nearly a mile wide, but anciently much narrower (Thucyd. iv. 8).

The word Navarino is explained as equivalent to Avarino, and is said to record an Avar settlement made here in the 6th century. The name Neocastro distinguishes the place from Palæocastro, the alleged site of the ancient Pylus, on the northern shore of the bay. Sphacteria was the scene of the famous blockade and defeat of the Spartans in 425 B.C.; and it was by the victory of the combined fleets of Great Britain, France, and Russia over those of Turkey and Egypt in the Bay of Navarino on October 27, 1827, that the independence of Greece was virtually secured.

NAVARRA, an inland province of northern Spain, lies between 41° 57′ and 43° 18′ N. lat., and between 40′ and 1° 15′ 50″ W. long.,—its greatest length from north to south being 90 miles, its breadth from east to west 86 miles, and its area 4046 square miles. The population in 1877 was 304,184. It is bounded on the N. by France (Basses Pyrénées), on the E. by Huesca and Zaragoza, on the S. by Zaragoza and Logroño, and on the W. by Alava and Guipuzcoa. It is traversed from east to west by the Pyrenees and by the Cantabrian mountains, their continuation in the west; and almost the whole of the province is overrun by the ramifications of this great central cordillera, which on the north-east especially presents an almost impassable barrier, and encloses numberless secluded pastoral valleys. From Navarra there are only three practicable roads for carriages into France,—those by the Puerta de Vera, the Puerta de Maya, and Roncesvalles. The highest summits in the province are those of Altoviscar (5380 feet) and Adi (5220 feet). Southward of a line drawn from Sanguesa by Tafalla to Estella the country presents a series of descending but comparatively level terraces, until the Ebro is reached. The chief river flowing towards the Atlantic is the Bidasoa, which rises near the Puerta de Maya, and after flowing southwards through the valley of Baztan takes a north-easterly course, and for a short distance above its outfall at Fuenterrabia constitutes the frontier between France and Spain (Guipuzcoa); by far the larger portion of the province has its drainage to the Mediterranean through the Ebro, whose main feeders there are the Ega and the Aragon with its tributary the Arga. The geology of the province will be best explained in connexion with that of the Pyrenæan system and of the country as a whole. Gypsum, limestone, freestone, and marble are quarried; there are also mines of copper (near Leiza), lead (Leiza and Vera), and iron (Goizueta and the valley of Aezcoa), employing a considerable population; and rock-salt is mined at Funes and Valtierra. There are numerous mineral and thermal springs, but none of more than local fame. The hilly districts are almost entirely appropriated to forests and pasture, the most common trees being the pine, beech, oak, and chestnut. Much of the lower part of the province is well adapted for agriculture, producing the various cereals in remunerative abundance; the principal fruit grown is the apple, from which cider is made in some districts; hemp, flax, and oil also occur, and the cultivation of the mulberry for the silkworm is not unknown. Game, both large and small, is abundant in the mountains, not even the bear being wholly extinct; and the streams abound with trout and other fish. The manufactures of the province, which are not important, include cloth and paper; wool, iron, salt, hides, and liquorice are the chief exports. Administratively Navarra is divided into five "merindades" or departments,—those of Pamplona, Tafalla, Olite, Estella, and Sanguesa. The capital is Pamplona, with a population of 25,630. It is connected by rail on the west with Alsasua on the trunk line between Madrid and San Sebastian, and with the Ebro valley in the south. There are no other railways in the province. Besides Pamplona, the only ayuntamiento with a population exceeding 10,000 is Tudela (10,086); Baztan comes next with 9931.

Navarra, or Navarre, along with Guipuzcoa, at the time of the Roman conquest formed the territory of the Vascones, which afterwards became part of Hispania Tarraconensis. Never thoroughly subjugated by the Romans, the Basques or Navarrese offered considerable resistance to the Visigothic kings in the 5th and 6th centuries, and afterwards in the 8th, with more success, to the Moors. In 778 Charlemagne succeeded in imposing his yoke upon them, but with the assistance of their old enemies they soon afterwards asserted their independence of the Franks. Garcias Ximenez (860) is named as having been their first king. In the beginning of the 11th century Sancho III., el Mayor, had made himself sovereign of Castile and Leon as well as of Sobrarve and Aragon, but before his death in 1035 divided his extensive dominions into four unequal parts, Navarre being assigned to his son Garcia III. Garcia's son Sancho IV. was overthrown in 1076 by a cousin, Sancho I. of Aragon, in whose line the two crowns remained united

until the election of Garcia Ramirez on the death of Alphonso I. (VII. of Castile). In 1234 Theobald, third count of Champagne, was crowned at Pamplona as Theobald I., having been adopted as heir by Sancho VII., and through Joanna, the granddaughter of Theobald, who married Philip the Fair of France in 1284, the crowns of France and Navarre became united in the person of Louis X. They were again separated on the death of Charles IV. of France without male issue; Joanna II., the daughter of Louis X. and wife of Philip, count of Evreux, was crowned queen of Navarre at Pamplona in 1329. Her great-granddaughter Blanche was married first to Martin of Sicily and afterwards to John, son of Ferdinand of Aragon; the second after her death made himself king of Navarre in spite of the claims of his son Charles, taking the title of John II. He was followed in 1479 by his daughter Eleanor, the wife of Gaston de Foix, and after her death in the same year Francis Phœbus, her grandson, succeeded, being crowned in 1482. At his death (1483) his sister Catherine, wife of Jean d'Albret, naturally succeeded, but, the latter having fallen under the papal ban, Ferdinand the Catholic in 1512 seized the whole of what is now Spanish Navarra, only the small portion of the kingdom on the French side of the Pyrenees being retained by Henry II., son of D'Albret (1516). Her grandson, Henry III. of Navarre, became king of France (Henry IV.) in 1589, and united non-Spanish Navarre to the French crown in 1607.

NAVARRETE, Juan Fernandez (1526–1579), surnamed El Mudo (The Mute), an eminent Spanish painter of the Madrid school, was born at Logroño in 1526. The illness which deprived him of his hearing occurred in early infancy, but at a very early age he began, it is said, to express his wants by sketching objects with a piece of charcoal. He received his first instructions in art from Fray Vicente de Santo Domingo, a Hieronymite monk at Estella, and afterwards he visited Naples, Rome, Florence, and Milan. According to the ordinary account he was for a considerable time the pupil of Titian at Venice. In 1568 Philip II. summoned him to Madrid with the title of king's painter and a salary, and employed him to execute pictures for the Escorial. The most celebrated of the works he there produced are a Nativity (in which, as in the well-known work on the same subject by Correggio, the light emanates from the infant Saviour), a Baptism of Christ (now in the Madrid Picture Gallery), and Abraham Receiving the Three Angels (one of his last performances, dated 1576). He executed many other altarpieces, all characterized by boldness and freedom in design, and by the rich warm colouring which has acquired for him the surname of "the Spanish Titian." He died at Toledo in February 1579.

NAVARRETE, Martin Fernandez de (1765–1844), Spanish historian, was born at Abalos, Logroño, in 1765, received his early education at the seminary in Vergara, Guipuzcoa, and entered the navy as a midshipman in 1780. His ship was engaged in the unsuccessful operations against Gibraltar in 1782, and afterwards in the suppression of Algerine pirates. Ill-health compelled him for a time to withdraw from active service, but he was able to devote the leisure thus forced upon him to historical research, and in 1789 he was appointed by the crown to examine the national archives with a view to the publication of a series of documents relating to the maritime history of Spain. Rejoining the navy in 1793, he was present at the siege of Toulon, and afterwards received command of a frigate. From 1797 to 1808 he held in succession various important posts in the office of the minister of marine. In 1808 the French invasion led to his withdrawal to Andalusia, and the rest of his life was entirely devoted to literature. In 1819 appeared, as an appendix to the Academy's edition of *Don Quijote*, his *Vida de Cervantes*, the best biography of the great poet and humorist that has as yet been written, and in 1825 the first two volumes of the *Coleccion de los Viajes y Descubrimientos que hicieron por Mar los Españoles desde fines del Siglo XV.*,—characterized by Humboldt as "one of the most important historical monuments of modern times,"—were published. The third followed in 1829, and the fourth and fifth in 1837. After the publication of his *Life of Cervantes*, Navarrete's literary merits received ample recognition: various public posts were conferred on him, including that of director of the hydrographical institute, and in 1837 he was made a senator and director of the academy of history. At the time of his death, which occurred on October 8, 1844, he was assisting in the preparation of the *Coleccion de Documentos Ineditos para la Historia de España*. The last two volumes of the *Coleccion de Viajes* were published posthumously, as also were a *Disertacion sobre la Historia de la Nautica* (1846) and the *Biblioteca Maritima Española* (1851).

NAVIGATION

NAVIGATION is the art of conducting a ship across the ocean. It is here treated to the exclusion of seamanship, which forms a distinct subject. The present article will give, first, a view of the history of the art from the time of the epoch-making voyages of Columbus and the Portuguese, with special reference to advances made in England, and then a sketch of practical navigation as the art now stands.

Up to the time of the Portuguese exploring expeditions, sent out by Prince Henry, which led to the discovery of the Azores in 1419, and the rediscovery of the Cape Verd Islands in 1447 and of Sierra Leone in 1460, navigation had been conducted in the most rude, uncertain, and dangerous manner it is possible to conceive. Thousands of years had passed without the least improvement being introduced, except the magnetic needle about the beginning of the 14th century (see Compass and Magnetism). Prince Henry did all in his power to bring together and systematize the knowledge then obtainable upon nautical affairs; he also established an observatory at Sagres (near Cape St Vincent) in order to obtain more accurate tables of the declination of the sun. John II., who ascended the throne in 1481, followed up the good work of his grand-uncle. He employed Roderick and Joseph, his physicians, with Martin de Bohemia, from Fayal, to act as a committee on navigation. They calculated tables of the sun's declination, and invented the astrolabe, or at least recommended it as more convenient than the cross-staff. The king established forts and settlements on the coast of Africa; that at St George de la Mina was on the Gold Coast, showing by the position a great geographical advance.

The backward state of navigation at this time is best understood from a sketch of the few rude appliances which the mariner had. He had a compass, a cross-staff or astrolabe, a moderately good table of the sun's declination, a correction for the altitude of the pole star, and occasionally a very incorrect chart. The first map or sea chart seen in England was brought by Bartholomew Columbus in 1489, and the first map of England was made in 1520. Decimal arithmetic was invented by Simon Stevin about the end of the 16th century. Watches were unknown till 1530, and immediately Gemma Frizon or Frisius seized the idea for the purpose of ascertaining the difference of longitude between two places. They were too rough to be of use, and their advocate proposed to correct them by water-clocks or sand-clocks. Almanacs were first published in Poland in 1470, and in London three years later. These contained tables of the sun's declination and that of many of the stars, and tables for finding

the latitude by the pole star and the "pointers." There was not till 1607 any means whatever of measuring a ship's progress through the water, and none in general use till twenty or thirty years later (see LOG).

The "cross-staff" appears to have been used by astronomers at a very early period for measuring heights and distances, more recently by seamen for measuring altitudes. It was one of the few instruments possessed by Columbus and Vasco da Gama. The old cross-staff, called by the Spaniards "ballestilla," consisted of two light battens. The part we may call the staff was about an inch and a half square and 36 inches long. The cross was made to fit closely and to slide upon the staff at right

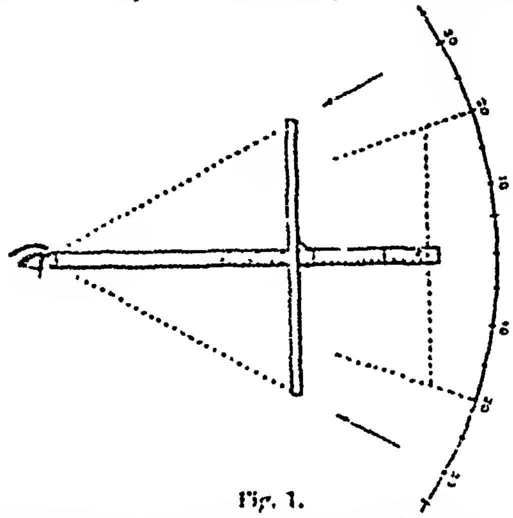

Fig. 1.

angles; its length was a little over 26 inches, so as to allow the "pinules" or sights to be placed exactly 26 inches apart. A sight was also fixed on the end of the staff for the eye to peep through at the other two sights and objects to be measured. It was made by describing the angles on a table, and laying the staff upon it (fig. 1). The scale of degrees was marked on the upper face. Afterwards shorter crosses were introduced, so that smaller angles could be taken by the same instrument. These angles were marked on the sides of the staff.
